Three dollars a year

Continental Motors will be on exhibition at the Chicago Automobile Show, Coliseum Gallery 50-51.

There is no one factor, of course, that is responsible for the dependability of the Red Seal Motor. Red Seal performance is the result of a combination of factors each of which contributes toward the perfection of the finished motor. ¶But in the Continental Testing Room there is just a suggestion of the eternal care that is largely responsible for Red Seal quality. For here, newly completed Red Seal motors are tested under their own power—dismantled—inspected—re-assembled and tested again—all as part of the program for upholding the quality that is everywhere associated with the Continental Red Seal.

VOLUME XLIV

(Jan. 6 to June 30, 1921)

OF

Automotive Industries

Every effort has been made to present in these pages a table of contents for six months' issues of AUTOMOTIVE INDUSTRIES that it may serve as a guide to the authoritative current and reference articles printed. This index will also serve as a reference for those who wish to use the news pages of this publication as a guide to the history of the material development of the industry. This work is in keeping with our efforts to make this publication entirely representative of the great industry.

VOL. XLIV NEW YORK—THURSDAY, JANUARY 6, 1921 No. 1

Are Your Dealers Discontented? A Good Many Dealers Are!

We have heard so much about discontent and the prospective shakeup in dealer representation that we have obtained intimate opinions from 13 representative men. We believe these replies form a very important contribution to the research that must be made into the subject of automotive vehicle selling.

By Clyde Jennings

A FEW days ago there came into the Class Journal office a man who wanted to talk over the prospects of manufacturing a car. This man has a completely equipped factory; a satisfactory (to him) design of a car that has successfully made the experimental runs. What he needs is a dealer organization. When that is completed, he will be ready to give the word to begin manufacturing as soon as he thinks the selling situation is right.

What we want really to tell is **this man's plan for building up a dealer organization.** He has spent several months studying the situation as it presents itself and here is his conclusion:

> **There are many good dealers and distributers who are disgusted with the methods under which they have been working. They believe that they have been threatened, forced to do this and that, and have been given no voice whatever in the preparation of the article that they must pass on to the public. I am going to nose about among dealers and distributers, pick out some of these men and put them into my organization. I want 20 distributers and I am going to make these men into a selling board and the last word on the car design and method of selling will be their word. In other words they will come into my organization as directors, representing their dealers, and have a voice in the making of the article they are to sell.**

A FEW weeks ago the Uruguay legislature passed a bill making unlawful a merchandising contract with a foreign firm that could be cancelled by a 60-day notice.

The reason for this action is said to have been the cancellation of a sales contract between an American automotive manufacturer and an Uruguayan dealer. In this case, so it is reported, some vehicles shipped to this dealer before the cancellation notice was mailed did not reach him until after the cancellation became effective. The idea that influenced the legislators was that this dealer's investment in his business and the effort he had put into building up a good will were swept aside **without a hearing of his side** of the case.

THESE two incidents would indicate that manufacturers have been somewhat high handed in their dealer operations. The two incidents might be

construed to indicate that the present methods could be improved. Of course, none of us expects that any manufacturer will ever build a dealer organization that will be 100 per cent efficient and contented. Human nature has not reached that point as yet.

But it is reasonable to expect that the state of mind of the dealers and distributers would be such that a prospective manufacturer would not expect to build a worthy organization on the ruins of another's structure, and that legislatures need not be called in to protect dealers.

Now what are the facts as to the present state of mind of the dealers? There is only one place to find the answer, and that is the men most concerned—the dealers.

So the question was put to some of the most important dealers and distributers in the country. The question was asked by a man who knows the men who wrote the replies we will quote. The questioner knows these men well, he knows their families and their homes and so the men are truthful to each other.

We will say further, these men did not know that they were writing for publication, nor do they belong to the same organization. Probably 25 cars are handled by these men, as several of them sell more than one line of automobiles.

The question was this:

In your opinion do you believe that there will be a general shakeup of dealer representation? Will dealers quit their lines for the reason that they believe that they have not had a square deal from their factories? What, in your opinion, will happen?

Now come the answers. They are an important document, as important a document, I believe, as has ever been contributed to the sales end of the automotive business. Remember, in reading what follows, that you are reading the testimony of men who have sold motor cars for years. Some of them have been in the business twenty years, and all of them long enough to become recognized units in the business. They are not interlopers, nor are they mere observers. They are the men who have given a good account of themselves on the firing line.

Surely it is time for some manufacturers to stop, look and listen when such opinions are given by the best men in the business.

Just to keep the question in front of you as you read the replies, we repeat it here:

In your opinion do you believe that there will be a general shakeup of dealer representation? Will dealers quit their lines for the reason that they believe that they have not had a square deal from their factories? What, in your opinion, will happen?

1—I believe there will be a general shakeup and have talked with some of the distributers and factory branch managers and it is safe to assume that there will be a general shakeup and many of the dealers will be bothered. Here's what happened:

In many cases during the non-delivery period, many dealers have taken on lines on which they could get deliveries or hoped to, and where they previously carried one or two lines, they are now carrying four or five. In many instances they have done this, believing they have not received a fair deal from their factories. In most instances, perhaps, it was the fact that the factories could not make delivery. What is going to happen is this:

Many of the dealers who have been handling certain lines for many years will change and go on to other lines because of special and extra inducements given by these manufacturers to beat out the "other fellow." Of course, some of the better lines will not suffer from this materially, but some will. It will be a question here of the survival of the fittest.

2—No doubt there will be some changes to take place among the dealers, part of which will be caused by the desire of the factories to get better connections and part by the fact that some dealers who have sold cars that are more or less undesirable will endeavor to obtain better connections.

I believe this situation will be very much like the recent labor situation. When there are plenty of jobs it is rather hard to hold laboring men in line. In other words, a little competition should do no harm. It is my belief that there are a number of dealers in some cases handling very excellent lines who have no more right to success in business than I have to a place in heaven.

Anyone who is familiar with the automobile industry can testify that in no industry is there such a large number of men who are apparent successes but who, as a matter of fact, have been carried along by the current. No doubt, when it becomes a matter of selling automobiles rather than telling the people when you can give them a car, many of this class of dealers will be eliminated.

For many years I have found it very hard to understand how some fellows have been able to remain in business when you take into consideration the methods pursued in their various establishments. Some of the so-called successful automobile establishments remind one very much of the old-fashioned livery stable and one of the second-rate at that.

It must be taken into consideration that there are many distributers and dealers, as well as manufacturers in the business who had no right to start in the first place. Due to an over-liberal credit situation which existed up until about a year ago, many dealers started in the business on a very extensive scale on a very limited capital. I have a very intimate knowledge of one outfit that started on barely enough money to unload one carload of automobiles. Due to some particular good fortune, this concern has been able to remain in business and has at last got its finances on a rather substantial basis.

I believe that in the future to handle the automobile business, it will require more capital. In other words, fellows who have started in the past would be unable to duplicate the feat.

This, undoubtedly, will result in a more substantial class of dealers with better methods and more profit to all who are in the industry.

3—Dealers who have been handling several different lines will quit all but possibly two lines. In some cases, they will handle only one line.

4—Dealers cannot afford to quit their lines, even though many have just grievances. At present, factories hold the reins and distributers and dealers alike must comply with their wishes and accede to their demands.

5—My opinion is that there is going to be some awful change. I have received quite a few letters from distributers and dealers with whom I was not connected at all in the business world, who have told me that they were waiting for the time to come when the cars would be plentiful and they could tell the manufacturers to go to hell.

I am giving you this just as they put it to me.

My opinion is that if the manufacturer does not do something soon to get his dealer organization together and regain their confidence that the different manufacturers will be bidding against each other trying to get the best representative, because he, the manufacturer, will get desperate and will do these things in order to save his factory organization.

6—There will be no shakeup in our dealers. Our factory has been running almost continually. I do know, though, of a lot of dealers who are dissatisfied with the service they receive from their factory and are willing to jump to some other make of car, but the dealers who are handling cars made by reputable manufacturers will not give up their agencies and the factories are not increasing the number of dealers, so we hardly know what will become of the dealers who want to jump.

I imagine that a lot of dealers are going out of business. I know that a lot of Blank dealers are going to and have, either because they could not get the cars, the cars were no good, made bad deals, and cut prices and did not know how to conduct their business.

7—Some dealers who have good lines and are not well financed will, undoubtedly, be forced out, and the dealers with poor lines who are well financed will ease into the place vacated by the former. This is natural. I do not believe that dealers will quit their present lines unless for the purpose of securing a better one.

The successful automobile man is an optimist and lives in the belief that things will change for the better to-morrow. They look forward to improved relations with the factory on the theory that "further up the creek you go, the better the fishing."

8—I do believe there will be a general shakeup of dealer representation when cars become more plentiful, but I do not think that this will take the form of changing agencies. Rather the dealer will go out of business, because I am satisfied that there are too many dealers and too many manufacturers in this business at this time.

9—The need of education in the automobile dealer industry along merchandising principles, as laid down by other successful lines of business, when automobile dealers have to sell their cars, will bring forth many changes and shakeups because the dealer does not know how much it costs him to do business. Dealers will quit more on this account than because they have not been treated fairly.

In most cases, their organizations will have become so badly disrupted they will not know who or what to blame. Furthermore, there are many dealers and distributers organizations who are handling the product of certain manufacturers whose unfairness has caused them loss of money, prestige and so forth, who will switch from their present position to take on the line of automobiles from the manufacturer who has a clearer vision of the automobile industry which the dealer or distributer occupies.

10—There is going to be quite a change in dealer representations throughout the country, as I believe that the dealer who is well organized, which includes sufficient financial backing, will be in a position to obtain the pick of agencies.

There are many dealers who have not received a square deal from their factories and I believe that if this financial stringency continues that many dealers will be forced to retire, and this will leave the better dealers to command something from the factories and they will be in a position that they have never been in before.

11—I think the time is not yet here when dealers will give up standard profitable lines, no matter how they might feel. If the factories impose conditions which dealers find it hard to meet and still handle their outputs, some readjustment will have to take place. One factory, for instance, imposes a $15 national advertising charge on every car which we must pass on to the customer. I think the manufacturers of less known cars will suffer seriously under present conditions of contracts in view of coming competition and fall-off in the market.

12—This is entirely problematical in my mind. It is to be presumed that there will be several changes both from the dealer viewpoint and the factory viewpoint. Both may be justified. We are looking forward to some changes in our own distributing organization of dealers. Dead-wood is appearing; that is, those who cannot sell, but were able to take orders. We must have sellers in a buyers' market.

13—It is natural that every factory will look for the best dealer representation it can find. If it finds its present dealer complaining against the treatment received it will either mollify him or look elsewhere. The standard lines always will be well represented. I believe the average dealer continues to do business as long as possible with the factory he is familiar with, and **I believe that statistics will show that most cancellations are made by the factories.**

Yes, there are more questions.

This article and those to follow delve more deeply into the question of dealer-manufacturer relations than anything heretofore put on paper. The frankness and honesty of the replies to the questions must be their own defense. No names will be given in this treatment of the question. But we will endeavor to make plain to the manufacturer just what his dealer thinks about a number of very important topics, such as:

The bad taste left after the allotments in 1919.

Introduction of new models.
Careless factory inspection.
Poor assembly.
Price changes.
Dealer contract.

You will note in reading these answers that six men are outspoken in the opinion that there will be a big shakeup among dealers, while only three are outspoken against it and at least a part of the three give the opinion as referring only to the organizations they represent.

You will also note that five of these men speak out squarely that the dealers have not had a square deal.

According to A. P. Young, writing in *Engineering* (London), if a spark gap be connected to an alternator or transformer designed to produce about the same voltage as that generated by a magneto (say 10,000) at the usual frequency of 50 per second, owing to the comparatively slow rate of application of the voltage, the spark voltage will be much less than with a magneto, in which latter the secondary voltage builds up extremely rapidly. The ratio between the spark voltage with magneto current with an ordinary alternating current of 50 cycles per second is frequently known as impulse ratio.

New Model Lexington Car Uses Ansted Engine

Model T chassis similar to model S except for new engine. Latter is high speed type with overhead valves, novel rocking valve gear, and vacuum oil control. Large well heated inlet manifold cast integral with exhaust header. Hand brake is mounted on transmission. Makers set good precedent by furnishing more detailed specifications than are customary.

By J. Edward Schipper

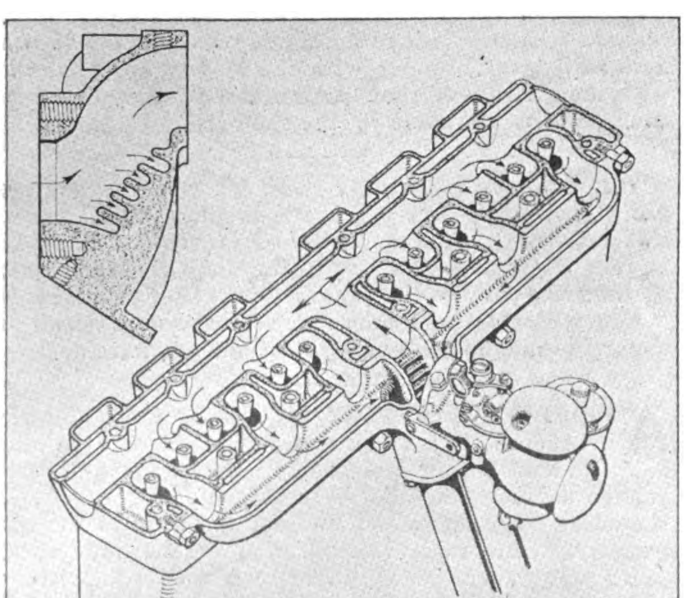
A NEW make of engine, the Ansted, features the new model of Lexington car. Otherwise, the new chassis is very similar to the model S (which will be continued), though the wheelbase has been considerably lengthened. For the present the new chassis will be fitted with seven-passenger and closed bodies only.

The Ansted engine is a valve-in-head type and is designed for operation at high rotative speeds, hence it is capable of giving considerably more power than the L head engine formerly used, though it is of the same piston displacement. Its maximum output of 73 hp. is obtained at 3200 r.p.m. It is of 224 cu. in. displacement and the maximum brake horsepower per cubic inch of displacement is 0.325.

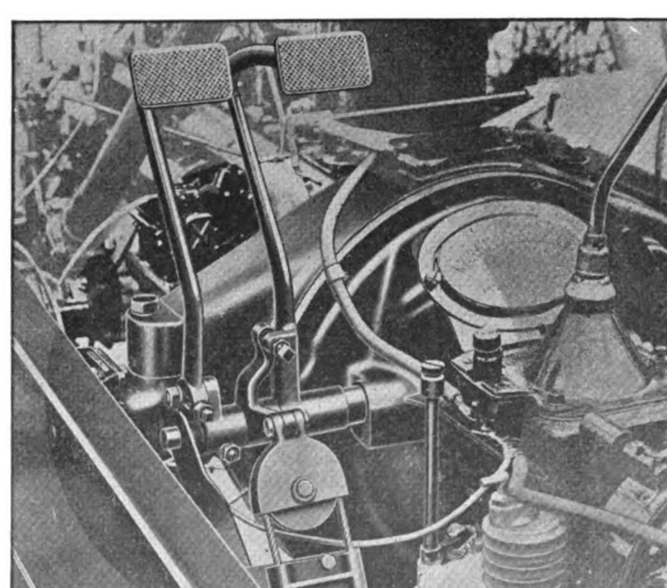
The cylinder barrels and upper half of the crankcase are in one casting, which makes a good manufacturing job. All finished surfaces of the block are at right angles or parallel to the bottom face of the cylinders. The water jackets are carried the entire length of the cylinder wall, and there are water spaces between adjacent cylinder barrels. The pressed steel underpan acts as an oil reservoir. The timing gear cover plate is so fashioned as to provide a suitable support for the electric generator.

The piston is a light cast iron shell, well ribbed and provided with only two rings. The piston pin is fastened in the connecting rod and bears in the piston pin bosses. There is a deep groove around the piston at the pin and there are two horizontal grooves on each side of the piston pin hole, so that oil scraped off the cylinder wall may be fed into the piston pin bearing. The two piston rings have a stepped joint and are provided with saw cuts to keep down oil leakage and also to assure perfect packing. Two of these rings were found to do the work of the three used on the experimental cars. The pistons have crowned heads and are machined on all exterior faces.

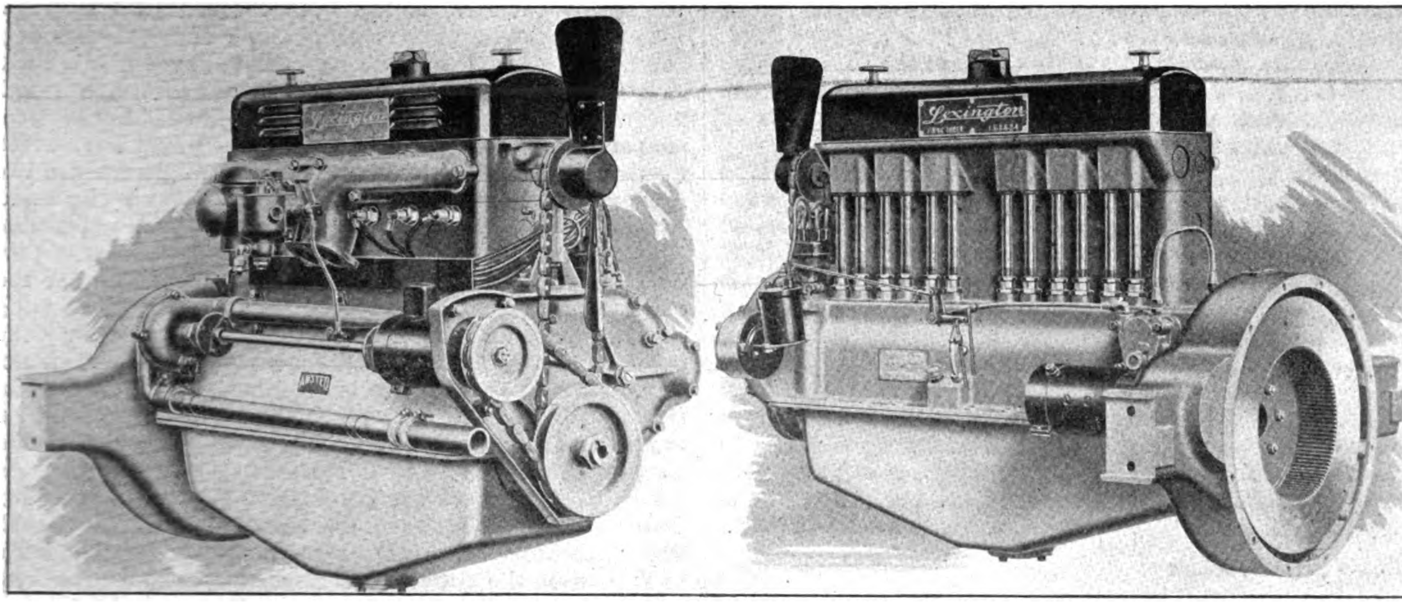
The connecting rod big end is lined with babbitt cast directly into the rod in order to insure good cooling of the bearing surfaces. In assembling, the rods are all weighed on a scale and grouped so that the differences in the weights of the big ends will not exceed 1/10 oz. In this weighing operation the piston pin end is mounted on a stationary knife edge and the big end on another knife edge located on the scale pan of the balance.



Sectional diagram of combined intake and exhaust manifolds, showing the vaporizing device employed on the Ansted engine used in Lexington car



Pedal controls, showing new equalizing device used on foot brake cables



The Ansted engine used in Lexington model T cars, showing belt drive for fan, generator and water pump

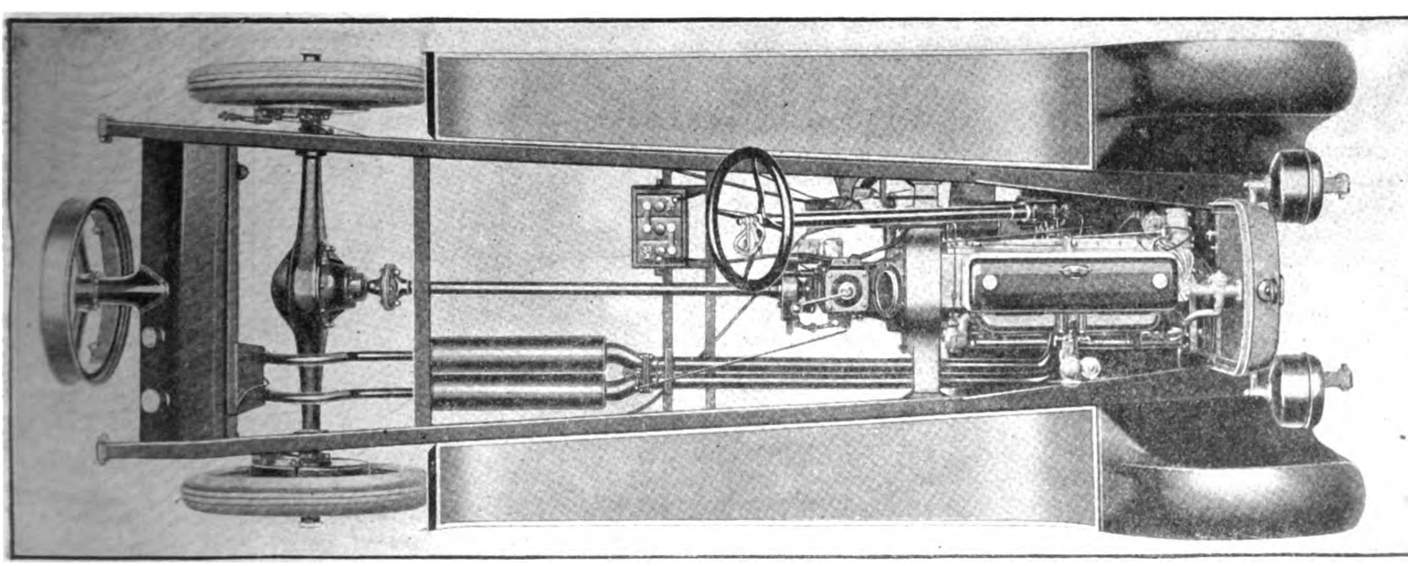
The crankshaft is unusually stiff and is very carefully balanced on a Carwen balancing machine before it is sent to the assembling department. The shaft is drop forged and has three main bearings. These are stepped so as to make the boring and reaming more economical and accurate. The bearings are assembled with a 0.006-in. shim between the case and the caps. They are reamed to size before the engine is run and do not have to be scraped or burned in. The front and rear bearings are provided with annular oil supply grooves, but aside from these there are no grooves in any of the main or connecting rod bearings.

The crankpins all have 0.4375-in. holes through their centers and the connecting holes from the main bearings to the pins and between the adjacent pins are all 11/32 in. in diameter. The crank cheeks are unusually heavy in section. Care has been taken to prevent oil leakage at both the front and rear ends of the crankshaft. At the front end there is a thrower ring on the inside of the crankcase, and a series of thin cork washers in the timing gear cover. At the rear end of the shaft there is an oil thrower ring turned integral with the shaft. Supplementing this there is a return thread on the shaft. At the rear end of the main bearing there is a small drain groove to prevent the oil under pressure from working out around the oil thrower ring.

The valve gear is unique in that the valve rocker arms are so mounted that their fulcrum points provide a variable rocker arm ratio from 1.265 to 3.047 to 1, which causes the valve to start and stop slowly, but to obtain greater and more rapid lift than would be possible with a constant ratio rocker arm. This prevents valve clatter at high engine speeds. Double valve springs are used to prevent synchronism between the valves and the rest of the mechanism from causing floating.

The valve tappets are easily accessible, as the tappet guides are held in place merely by the push rod inclosing tube. The tubes which inclose the push rods and through which the engine breathes are not fixed in place, but are pushed up into a counterbore in the bottom of the cylinder head and have a nut at the bottom end which presses down against the valve tappet guide. The latter is thereby held in place by the tube and the push rod completely inclosed. The valve tappet guides are grouped in pairs and have between them a small fillister head screw which prevents their turning in the cylinder casting.

The valve mechanism, including the rocker arms, is



Plan view of the series T Lexington chassis

completely inclosed, and the breather is located in the pressed steel valve cover on the top of the cylinder head. This insures a plentiful supply of oil to the valve rocker arms and the cup in the rocker arm is always full of oil. Valve clearance can be adjusted while the engine is running, which is said to be a great convenience.

A conventional three-bearing camshaft is used. The valve timing is as follows. Exhaust closes and intake opens at 10 deg. past top dead center; exhaust opens 50 deg. ahead of bottom dead center and intake closes 57 deg. after bottom dead center. The front bearing does not support the camshaft directly, but through a sleeve which carries the ignition distributor gear at its rear end and a flange at the front end. To the latter the camshaft gear is secured with four cap screws. End play is taken up at the forward end by a phosphor bronze thrust washer, which can be adjusted by a set screw in the timing gear cover. The flange on the camshaft collar takes the thrust in the other direction against the camshaft bushing.

The Fuel Vaporizer

A horizontal Rayfield carbureter is bolted to the combined intake and exhaust manifold on the right side of the engine. The mixture leaving the carbureter strikes a series of ribs that are heated by the exhaust and are directly in line with the incoming mixture. The mixture is deflected upward over them by the shape of the manifold and because of this change in direction, the heavier particles of unvaporized gas are thrown out of the mixture and precipitated on the ribs where the heat of the exhaust vaporizes them. The intake manifold measures 1¾ in. in diameter at all sections, hence the gas velocity is not sufficient to sweep unvaporized particles of the fuel off of the vaporizing ribs. The use of separate exhaust pipes and mufflers for each group of three cylinders prevents the overlapping exhaust from interfering.

One of the features of the lubricating system is the control of the oil pressure by vacuum. When the throttle is nearly closed and the engine is running light but little lubricant is needed. At such times there is a high vacuum in the intake manifold and the vacuum operated piston controlling the oil by-pass valve is raised against spring pressure, thus opening the oil by-pass. The oil pressure is thereby reduced and excessive oiling and smoking are prevented.

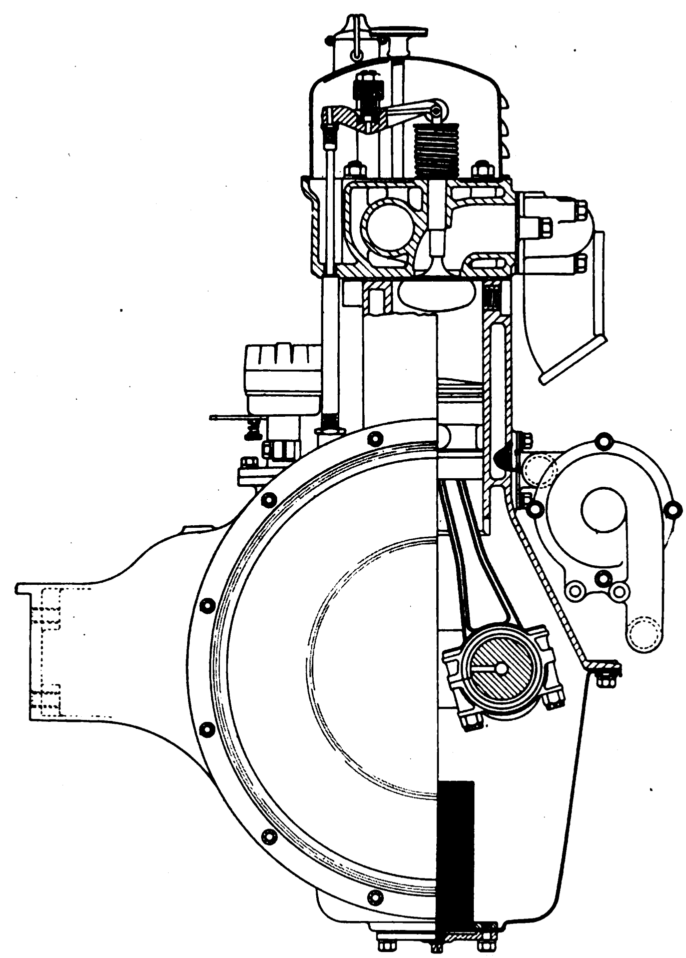
The oil pressure regulator is located at the front end of the crankcase immediately over the oil groove in the front main bearing into which the oil passing through the crankshaft is discharged. The plunger, which acts as a valve, extends down into the crankcase to the bearing groove. The piston is located in a small cylinder casting on the outside of the case. This cylinder is connected to the intake manifold. The system operates at a maximum pressure of 40 lb. per sq. in. The oil level in the crankcase is determined by means of a bayonet type gage.

A Rayfield regulator is used for the thermostatic control of the cooling system. The water is circulated by a new type of screw or turbo-impeller pump which gives a good head of water at low speeds and yet does not give excessive circulation at high speeds. The pump is open so that thermal circulation takes place if the pump drive fails. The pump is located at the rear end of the engine and is driven through the electric generator and a small shaft with two fabric universal joints. The water enters the cylinder jacket through a distributor pipe with three outlets, the object being to assure uniform distribution of water with consequent uniform cylinder temperature.

The use of only two timing gears and belt drives for the auxiliary apparatus is quite a departure from conventional practice. It has been found that two gears with 1.25-in. face and a spiral angle of nearly 24 deg. can be made from steel and iron and kept quiet if a third gear is not meshed with them. The gears are rough hobbed and then finished on a Fellows helical gear shaper. The fan, generator and water pump are driven by Graton & Knight 28 deg. V link belts. There are two independent belt drives, one for the fan and the other for the generator. The fan is mounted on an adjustable support, and adjustment for the generator drive is provided for by using a standard S. A. E. mounting for the electric generator, whereby the generator can be swung through quite an arc. This feature makes necessary the two universal joints between generator and water pump.

The new Ansted engine is combined with a transmission forming a unit powerplant and has a new design of multiple disk clutch which is now being made by the Lexington company. It contains five driving and six driven disks. There are ten floating Raybestos moulded friction rings in between the metal disks of saw steel. The Raybestos disks just clear the driven clutch drum so that when the clutch is released they cannot drop into the teeth of the driving member. Teeth of 10-12 pitch are cut on the inside of the driving and on the outside of the driven clutch members. The teeth on the clutch plates and the drums are formed on a Fellows gear shaper.

The most marked change in the chassis is the lengthening of the frame to give a 128-in. wheelbase in place of 120-in. The section of the side frame channel is now practically 9 in. in depth with 2-in. flanges, top and bot-



Transverse section of Ansted engine, showing "rocking chair" type of rocker arm used to increase and decrease valve acceleration in opening and closing

tom. The running boards are bolted to the bottom of the frame, thus giving it additional lateral strength. A cross member is carried from the underside of the running boards across the frame to prevent sag in the running boards and to stiffen the frame. The frame side members are now straight, the frame tapering from front to rear. This makes it possible to rest the body directly on the edge of the frame side members.

Both the emergency and the service brakes are unusual in their construction. The hand brake operates upon a drum located on the rear of the transmission. The foot brake operates on drums attached to the rear wheels, and is in the form of contracting bands. The hand brake is operated through a spring tensioning device so that it is possible to bring the car to a stop with very light pressure. The foot brakes are operated by a cable guided to each rear wheel by a heavy tube attached to the frame. The brake cables pass through loops or guides on the axle tubes and therefore are not affected by the slight rotation of the axle when the brakes are applied. Fabric universal joints connect the three speed selective gearbox with the rear axle. The drive is Hotchkiss type. The transmission is completely fitted with anti-friction bearings. The counter shaft and spigot bearings are furnished by Hyatt, while the main shaft bearings are New Departure.

The new body lines are very distinctive. The low hung effect of this body is obtained by carrying the doors right down to the frame line and cutting into the body sill to permit the door to shut. Sears-Cross locks are used in all the doors and dowel pins are provided in the side of the sill to hold the doors in position. This design is made possible by the deep, stiff frame.

A triangular instrument board located in the center of the cowl carries the ammeter and oil pressure gage, speedometer, switches and two-way valve for controlling the tilt of the head light.

The schedule of prices is as follows: Seven-passenger touring, $2985; four-passenger Sedanette, $4150; seven-passenger Salon Sedan, $4250.

Detail Specifications Model T Lexington Car

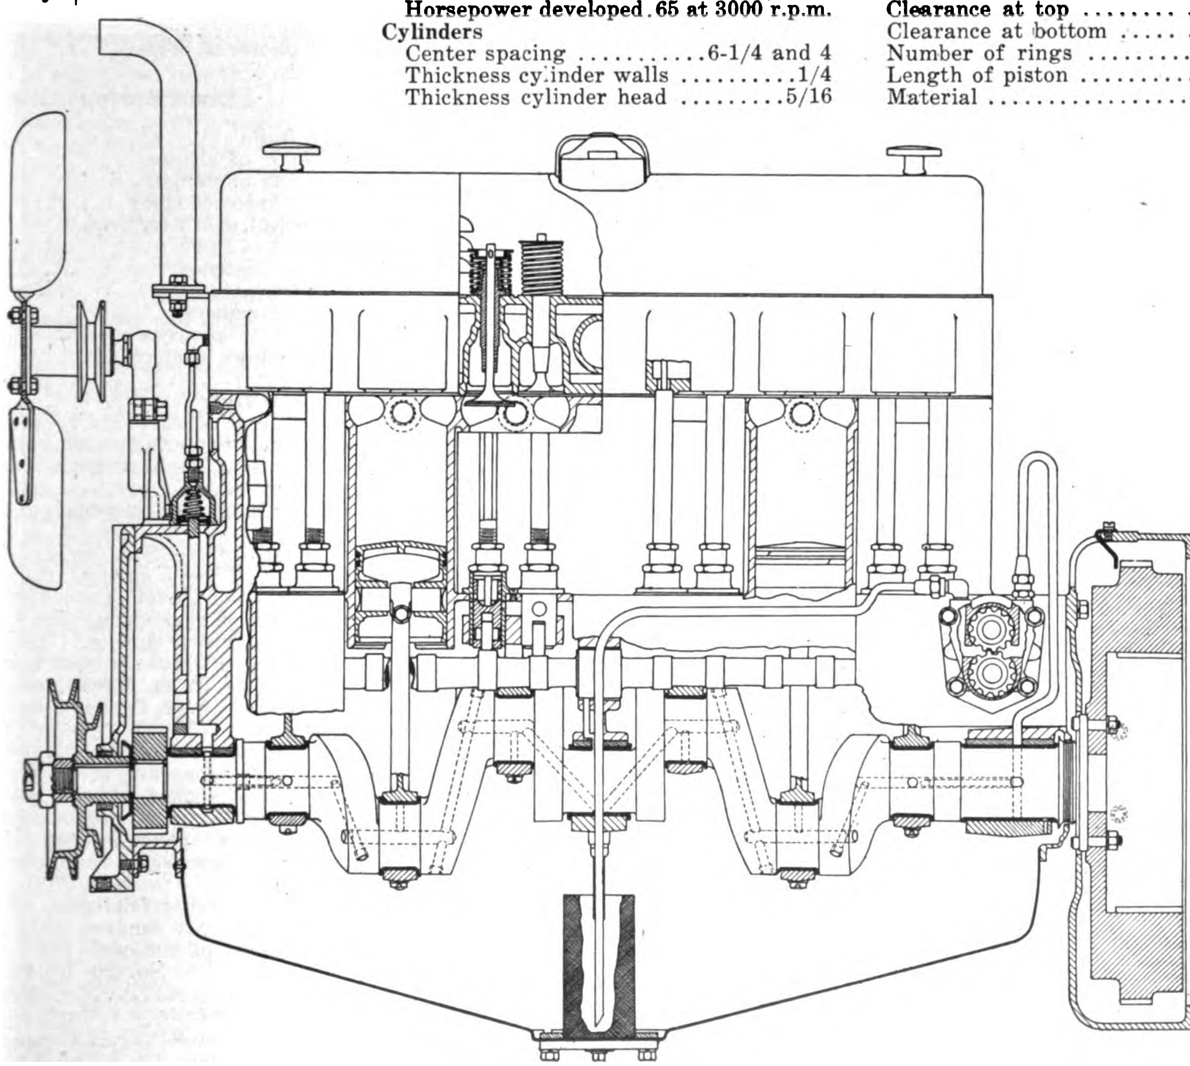
(All Dimensions in inches.)

Engine

General
- Bore 3-1/4
- Stroke 4-1/2
- Number cylinders 6
- Compression .... 80 lb.
- Clearance volume .... 10.5 cu. in.
- Piston swept vol. .... 37.3 cu. in.
- Total piston displacement .. 224 cu. in.
- Horsepower by S. A. E. formula .. 25.39
- Horsepower developed . 65 at 3000 r.p.m.

Cylinders
- Center spacing .... 6-1/4 and 4
- Thickness cylinder walls 1/4
- Thickness cylinder head 5/16
- Thickness water jacket-walls 3/16
- Mean water jacket space 13/16
- Material .... Cast iron

Pistons
- Thickness— head, 1/8; walls, 1/16
- Clearance at top .... .009 to .013
- Clearance at bottom .... .003 to .004
- Number of rings 2
- Length of piston 3-17/32
- Material .... Cast iron



Longitudinal section of Ansted engine, showing arrangement of oil pump, and flywheel with internal teeth to mesh with teeth on driven clutch plates

Piston Pins
Outside diameter .... .873
Inside diameter ....9/16 to 11/16
Material..No. 1020 S. A. E. steel, annealed and case hardened

Connecting Rod
Length center to center 8-1/2
Diameter cap bolts 7/16
Thickness of web 5/32
Thickness of flange 3/16
Width flanges 5/8
Material ....D. F. steel

Crankshaft
Front b'r'ng..1-3/4 dia. x 2-31/64 long
Second b'r'ng...2-1/4 dia. x 2-3/8 long
Third bearings....2-3/8 by 3-1/8 long
Crankpin ....2-1/4 dia. by 1-1/2 long
Cr's sec. long crank arm....3-⅛x1-¾
Cr's sec. short crank arm..2-¾x1-1/16
Diameter flywheel flange 4-7/8
Thickness flywheel flange 3/8
Material ..D. F. steel .40 to .50 carbon

Crankshaft Bearings
Thickness of shell 3/32
Material..........Babbitt-bronze back

Camshaft
Diameter 1-1/8
Frnt bearing..2-1/8 dia. by 1-1/4 long
Second bearing
1-3/4 dia. by 1-1/2 long
Third bearing ....1 dia. by 2 long
Diameter gear flange 3
Width of cam face 5/8
Radius follower circle 8437
Material..D. F. steel No. 1020 S. A. E.
Material camshaft bearing
Phosphor bronze S. A. E. No. 26

Valves
Clear diameter 1-5/8
Diameter of valve stem... .310 to .311
Lift .... .415
Material ....E. W. P. alloy

Valve Springs
Total load—main spring...45 to 50 lb.
Total load aux. springs....23 to 28 lb.
Material .....Round steel spring wire

Timing Gears
Pitch 10

Putting the Factory to Work on Service Jobs

Most factories have idle equipment and space. All lines of vehicles need more and better service. Here is a suggestion which, if applied, will enable manufacturers to use both space and equipment advantageously.

By Clyde Jennings

THE idea that service is the biggest single factor affecting the future of automotive transportation is gradually gaining recognition. New ideas for organized service and a realization that manufacturers must be responsible for the service in recognized shops and that it is their obligation to better the service in all shops (and do their utmost to eliminate the "gyp") are developing.

But the mail brought the other day an announcement which we believe will have a widespread influence for good. Also it probably will provide employment for some idle factory space and equipment. The idea is so good that we are going to pass it on. It is well worth the manufacturers' consideration. Here is the communication:

> There is a popular idea that after four or five years' use a motor truck must be sold to the junk dealer. This is entirely wrong and a very wasteful theory.
>
> We all know that there is a large number of the component parts of a good motor truck which really never wear out, or on which the wearing parts can be easily renewed. Such parts as the following represent quite a large proportion of the value of a truck, and are just as good at the end of four or five years as they were to begin with: Axles, wheels, frame, frame castings, gasoline tank, steering gear, radiator, carburetor and magneto, transmission case, clutch housing, etc.
>
> Motors with a large number of moving—and consequently wearing—parts, need overhauling and replacement from time to time as is only reasonable. Tires of course have to be replaced, and springs will eventually lose their life. Transmission gears may wear and need replacement. But there is no justification for practically throwing away so much valuable material that doesn't wear out at all.
>
> The work of RECONDITIONING a used truck is a much bigger proposition than what we usually mean by an annual overhauling, and can only be properly undertaken by the factory that originally built the truck.
>
> RECONDITIONING calls for the following:
>
> 1. All cylinders to be rebored and standard oversized pistons fitted, with the understanding that if the motor needs a very large number of new parts in order to put it in first-class shape, with a consequent considerable cost, in some instances it is more advisable to install a complete new engine.
> 2. Brand new tires should be fitted on all wheels.
> 3. All springs should be renewed, and all parts including transmission gears that are not as good as new should be replaced by new parts.
> 4. The testing of a RECONDITIONED truck should be as exhaustive in all respects as the testing of a new machine.
> 5. The factory should give its original guarantee as given on a new truck covering any machine RECONDITIONED at the factory.
>
> You are doubtless aware that in locomotive practice locomotives are RECONDITIONED at regular intervals, and by this means the life of the railway locomotive is almost indefinite, some engines being in active service for twenty or thirty years. The same policy is applicable to trucks.
>
> The work of general overhauling a truck can be handled by our dealers, but the work of RECONDITIONING, which is quite different, is a factory operation. It begins with the entire dismantling of the chassis and the inspection of all parts, the rejection of those that are imperfect and their replacement by new parts, the reassembling of the chassis and the same road test and final inspection and factory guarantee as goes with a new machine.
>
> The result of this is that the RECONDITIONED machine goes back to its owner ready to make a fresh start.
>
> We are prepared to undertake this work at the factory and on trucks owned in the vicinity of Detroit, we are prepared to give immediate estimates of the cost of such work. and on trucks that are located at a distance from Detroit, we are willing to send an expert to inspect and make an estimate, providing that if the truck is sent to us for RECONDITIONING we will make no charge for the time and expenses of our expert's appraisal, but if it is decided not to have the work done, we will expect our customer to pay the traveling expenses only occasioned by our expert's trip.
>
> The railroads are moving freight very freely at the present time and trucks can be shipped into Detroit from a radius of 500 to 1000 miles at a freight expense of probably not more than from $50 to $100 each way, and under existing conditions the railroads will deliver them to us quickly and they will get back to you quickly when we ship them out again. We invite immediate correspondence on this proposition, as it is difficult to cover it fully in one letter, but all Acason owners will, we are sure, appreciate the economical possibilities of the plan herein outlined.
>
> In some cases when desired trucks of previous years' models can be reconstructed and brought up to the specifications of our 1920 new series with 4-speed amidships transmission, etc.
>
> Particulars of our recommendations on these points can be given to each individual owner.
>
> ACASON MOTOR TRUCK COMPANY.

This idea can be applied to other vehicles than trucks. Before the big manufacturing rush came, a motor car factory located outside the Detroit district had excess paint shop space except in the very busy season. It was the practice of this factory to solicit among its dealers painting jobs. The amount of such work sent to the factory was surprising. Cars were driven several hundred miles for this work and many owners who had refused to listen to the solicitor who wanted to repaint the car in a dealer's shop gladly accepted the invitation to have the vehicle repainted in the factory.

Probably the belief that the vehicle would be better painted in the factory was unfounded, but it existed. While the chassis was waiting for the painting, it was examined, a statement of condition, the price for making needed repairs and any advice the factory experts saw fit to give. This became a source of considerable revenue, helped small dealers and had a good effect on owners.

A New Dual Reduction Truck Axle

Latest model of Mack truck uses Hotchkiss drive and novel spring mounting. Emergency brake on propeller shaft and service brakes on wheels. Makers consider dual reduction superior to worm drive, which is discontinued. Continue chain drive model, regarded best of three types.

By P. M. Heldt

CHAIN drive for motor trucks has one ardent supporter in the American truck industry—the International Motor Co., manufacturers of Mack trucks. The large trucks of this company always have been fitted with chain drive exclusively, while the smaller trucks, known as Model AB, have been built with either chain or worm drive, at the customer's option, for the past several years. The company has never been very enthusiastic about the worm drive, but in view of the public demand for shaft drive, it furnished worm drive trucks when asked for. Ever since the introduction of the AB truck, the engineering staff of the company has been making a study of different forms of shaft drive, both European and American, and has built and tested various experimental rear axles. It has now decided to discontinue the worm drive and to offer instead a dual reduction drive axle. The chain driven AB model will also be continued.

The dual reduction axle has a drop-forged housing of the double banjo type, and this is said to be the only drop forged axle housing extending from hub cap to hub cap that is made in America to-day. The yoke at the center of the axle housing is placed at an angle of 45 deg. instead of vertically or horizontally. This brings the plane of greatest strength of the housing substantially parallel with the direction of the severest shocks on the axle, and has the further advantage of increased road clearance. Incidentally this arrangement of the rear axle yoke places the gear train at an angle and produces a straight line drive. A double reduction axle is naturally somewhat heavier than a worm driven axle, and in order to reduce this extra weight to a minimum, the gear carrier and cover plate, which are secured to opposite sides of the yoke of the axle housing, are made of aluminum alloy. As is customary in such axles, the first reduction is by a pair of bevel gears, and the second by a pair of spur gears, the spur ring being mounted on the differential. The spur pinion is formed integral with the jackshaft, and the bevel gear is mounted thereon in a most secure manner. All of the shafts in the rear axle are mounted on Timken tapered roller bearings. The bevel pinion shaft is supported by a cast steel carrier, which is bolted to the aluminum gear carrier. All bearing adjustments are made with the aid of shims. That is, instead of having a screw adjustment locked by means of a dog or key, the adjusting collar is screwed up tight against shims, and if it is desired to make an adjustment one or more of the shims have to be removed. This same method of adjustment is used on the jackshaft on which the bevel gear is mounted. All bearing adjustments can be made without disturbing the assembly of the parts, and either the differential, jackshaft or pinion-shaft can be removed without disturbing any of the other parts.

The gear carrier is held in position on the rear axle housing by four studs passing through the metal of the yoke. These studs serve also to hold the cover plate in position. In addition to these four studs, there are four bolts which pass through the flanges of the gear carrier and the cover plate but not through the metal of the axle housing. They serve to distribute the holding down pressure uniformly over the flange of the gear carrier. The axle housing is forged of chrome nickel steel, with the wheel spindles and the spring saddles integral. The driving shafts are of chrome vanadium steel.

The Hotchkiss drive being used, it was thought necessary to provide exceptionally heavy springs and the most secure fastenings for same to the axle housing. In this connection the integral spring saddles of the axle housing offer quite an advantage. The spring is held to the sad-

Transmission and clutch. Interrupted spline construction used to give greater rigidity and ease in sliding of gears

dle by means of four heavy studs, which pass through the saddle and through a spring pressure plate, and are provided with 1 in. nuts at the bottom of the spring saddle. As the driving thrust is transmitted through the springs, there is a considerable tendency to displace the spring lengthwise relative to the saddle. It was not thought expedient to rely on the center bolt of the spring to take care of this thrust, as is often done. Instead, the main leaf was formed with a circular ridge around the center bolt hole, which mates with a counter-sunk slot in the spring pressure plate. There is a similar slot at the center of the spring saddle, and a corresponding circular ridge on the bottom of the smallest leaf.

The Hotchkiss drive, of course, imposes increased load on the springs and all parts thereof, and this has been taken fully into account in the design of the axle. The spring eyes are 1¼ in. in diameter and are provided with self-lubricating bushings. At the forward end the spring bolt is supported in the bracket at both sides of the spring. There are two rebound clips on each side of the axle, and the bolt of each clip passes through an eye formed on one of the intermediate leaves, the clip being free on the spring, so as not to interfere with the spring action. The rear springs are 54 in. long and 3½ in. wide.

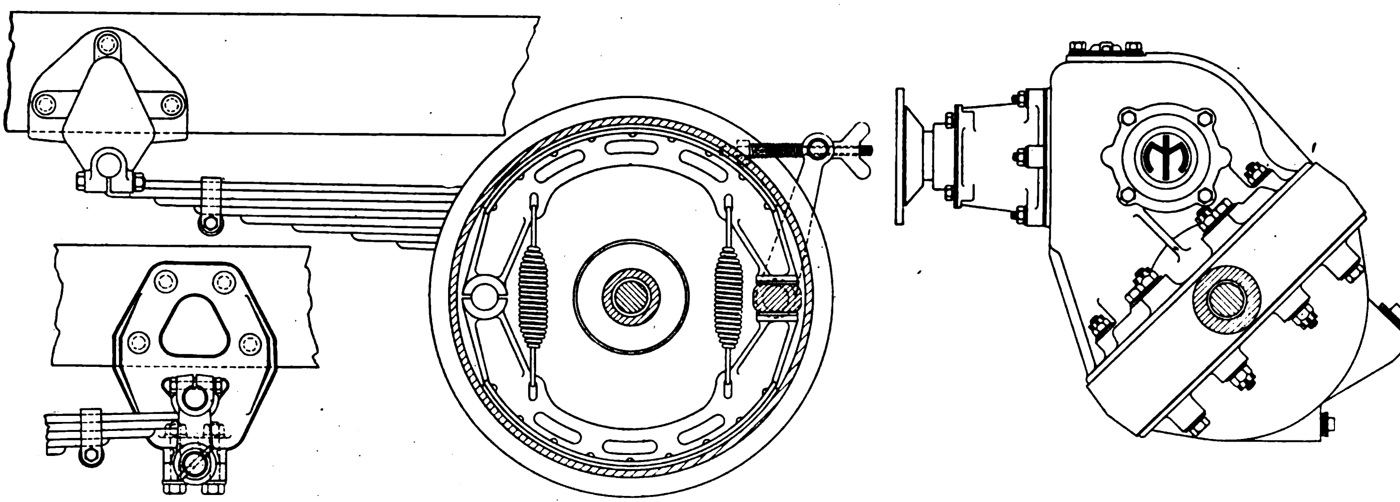
An oil filler is cast onto the cover plate of the axle housing, and this serves also as a level gage in filling the axle with oil. For the lubrication of the bevel pinion shaft bearings, an oil trough is cast in the upper part of the housing, into which oil is thrown by the revolving differential and crown gear. This oil flows by gravity through a suitable passage to the bearings. The road clearance is 10¼ in.

Four different gear ratios are offered with the dual reduction axle, viz., 5⅞, 7.6, 9¼ and 10¾. A change in gear ratio is quite easy to make, as the axle does not have to be dismantled, nor the adjustment of the differential disturbed. The only gears affected are the bevels, and only two new parts are required to get a new gear ratio, viz., the pinion shaft and the bevel gear. The pinion shaft is removed from the front and the jackshaft through the side. The new pinion shaft is installed and a new bevel gear substituted for the old one on the same jackshaft, by means of six bolts.

The adoption of the dual reduction axle has been accompanied by several other changes in design. One of the most noteworthy is in connection with the brakes. The truck is provided with a transmission brake and two rear wheel brakes, but, contrary to ordinary practice, the rear wheel brakes are the service brakes and the transmission brake is the emergency brake. The result of this is that ordinarily the braking effort is applied directly to the wheels and does not have to be carried through the transmission gear. Another reason for making the rear wheel brake the service brake is that with a given effort the driver cannot produce such a strong braking effect with the rear wheel brakes as with the transmission brake, and he is therefore less likely to abuse the tires.

The transmission brake is mounted on a short shaft carried on a one-piece drop forged frame, which completely surrounds the brake drum and is bolted to two cross members. The propeller shaft, therefore, is really in three sections, and four universal joints are used. These joints are much larger than those heretofore used by the International Motor Co., and the strain on them is correspondingly reduced. The transmission brake is 11 in. in diameter and 6 in. wide. It is of the contracting type, the sectors consisting of heavily ribbed drop forgings to which asbestos lining is secured by flat head screws. Each brake covers only about 100 deg. of the drum circumference, this comparatively small angular span having been found desirable to prevent excessive wear at the ends of each sector. The lining of each sector measures 6 x 12 in. The brake is operated by means of a double armed lever, whose axis extends across the chassis frame, the two arms being linked to the upper sector on one side and to the lower sector on the other side of the center. All bearing surfaces on the operating mechanism are liberal.

The new dual reduction AB truck will share with the chain driven model a number of other improvements, such as the new engine crankcase having 3 gal. oil capacity, as compared with 1⅞ gal. on the old engine, and the new Mack unit powerplant clutch and transmission, both built complete in the New Brunswick plant. In general design, this transmission is similar to the stock transmission formerly used, but it incorporates a number of improvements. The main shaft is splined, the splining being of the interrupted type, in which the gears are guided on ground surfaces between two sets of splines. This is said to give a much easier sliding action and



Spring anchorages, rear wheel brake and side elevation of rear axle. Note inclined position of differential housing

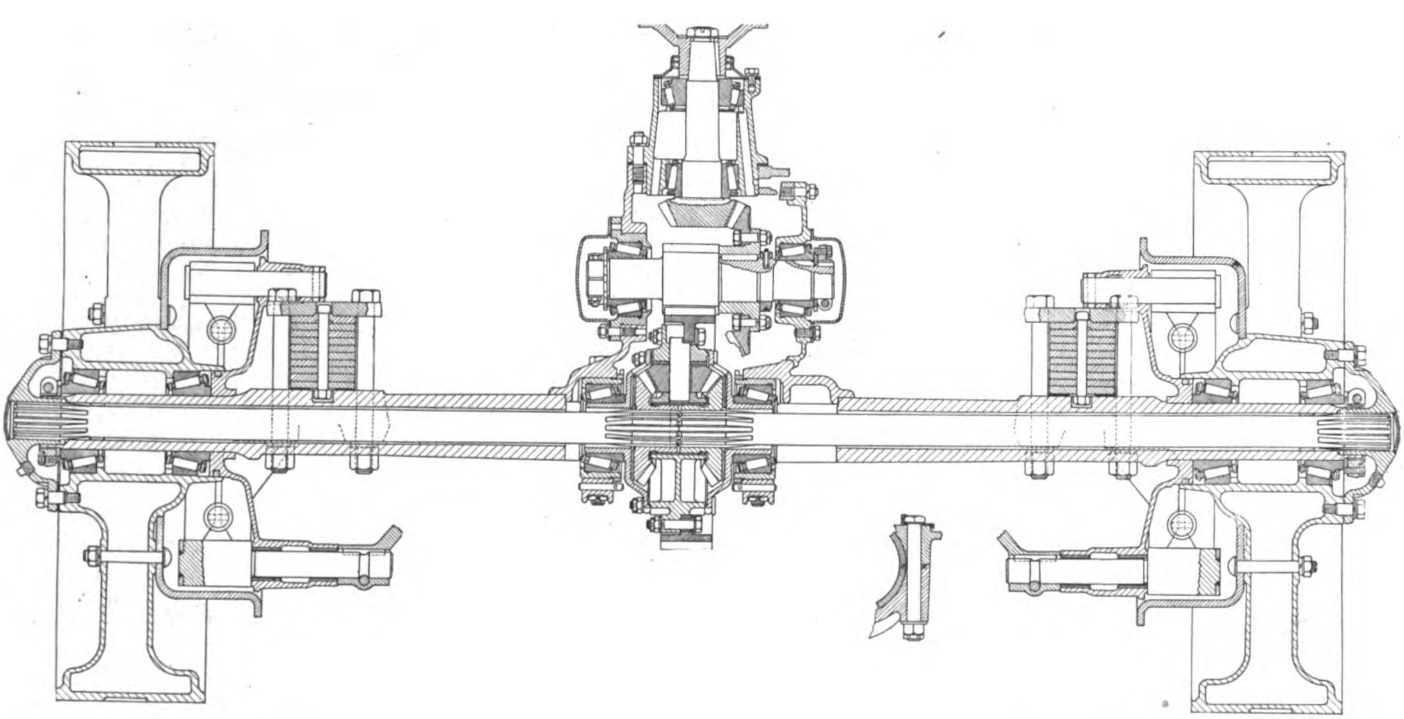
greater rigidity. The case is larger and holds more lubricant. An extension counter-shaft with a keyed power take-off is standard equipment. The standard S.A.E. tire pump mounting is provided on the side of the case to receive a pump for the inflation of pneumatic tires. The control has been simplified by the elimination of the reverse latch trigger. Instead, the lever is one solid piece and the reverse lock is released by depressing the entire lever.

A demonstration of three Mack model AB trucks was given before a number of trade paper representatives in the upper part of New York City on Dec. 15. The three trucks were equipped with chain, worm and dual reduction drive, respectively. They were all built to the same specification as to weight (approximately 5800 lb.), power delivered to the final drive, and gear ratios, the motors all being governed to 1275 r.p.m.

It was announced at the trial that one of the three engines had shown slightly greater power than the others and this had been put in the worm drive truck. The total reduction ratios were alike to within one per cent. (two being 9.25 and one 9.20). In each test three trials were made, with different drivers, so as to eliminate the personal equation. In the first test the trucks were allowed to coast down a slight incline with gears in neutral and all brakes released, and to run themselves out on the level at the bottom of the decline. Both the distance coasted on the level and the time from the start to the stop were measured. The results, averaged, were as follows:

Truck type.	Distance coasted on level.	Time from start to stop.
Chain	49 ft. 2 in.	1 min. 16 sec.
Worm	26 ft. 7 in.	1 min. 57 sec.
Dual red.......	45 ft. 2 in.	1 min. 16 sec.

In the second test, held on Exterior Street, the Bronx, the trucks were started from a point at the bottom of a hill averaging 16 per cent for its entire length of 80 yards, there being one point, about 30 yards from the top, where the grade is 18 per cent. The three trucks were started from the bottom of the hill, one at a time. Each was put



Horizontal section through rear axle, showing mounting and arrangement of bevel and spur gears in double reduction

in second gear as soon after the start as possible, and note was taken of the points where the drivers were forced to shift back to first gear. The time taken for the complete ascent of the hill was also taken. The results, averaged, were as follows:

Truck type.	Distance to shift to 1st speed.	Time to shift to 1st speed.	Elapsed time.
Chain	153 ft. 5 in.	29.6 sec.	51 sec.
Worm	16 ft. 7 in.	5.6 sec.	57 sec.
Dual red...	104 ft. 5 in.	22.3 sec.	52.6 sec.

In the third test all of the trucks were run, one at a time, part-way up the hill and left standing for 2 min. in order to allow the oil to drain off the gears of the final drive. The drivers were then given the signal to start and to ascend the hill as quickly as possible, notations being made of any changes in gear. All three trucks ascended the hill on first gear, the chain driven truck requiring 31 sec., the worm truck 32 sec., and the dual reduction truck 31 sec. A speed and acceleration test was made on a level course on Anderson Avenue, from Jerome Avenue north to West 162d Street. The trucks were started from a line, one at a time, and were accelerated as fast as possible, the distance and time in which the maximum speed was reached being noted. There was an observer on each truck, and the governor cover had been removed, so as soon as the observer noted the governor closing on direct drive—which showed that the maximum truck speed had been reached—he would pull a string and a vertically arranged chalk pistol on the truck frame would discharge, making a white mark on the roadway, so that the distance from the starting point could be accurately measured. The results with the three trucks, averaged for three trials, were as follows:

Truck type.	Time to full acceleration.	Distance to full acceleration.	Elapsed Time.
Chain	14.3 sec.	174 ft.	21.3 sec.
Worm	16.7 sec.	190 ft. 1 in.	21.6 sec.
Dual red...	15.3 sec.	181 ft. 2 in.	21.6 sec.

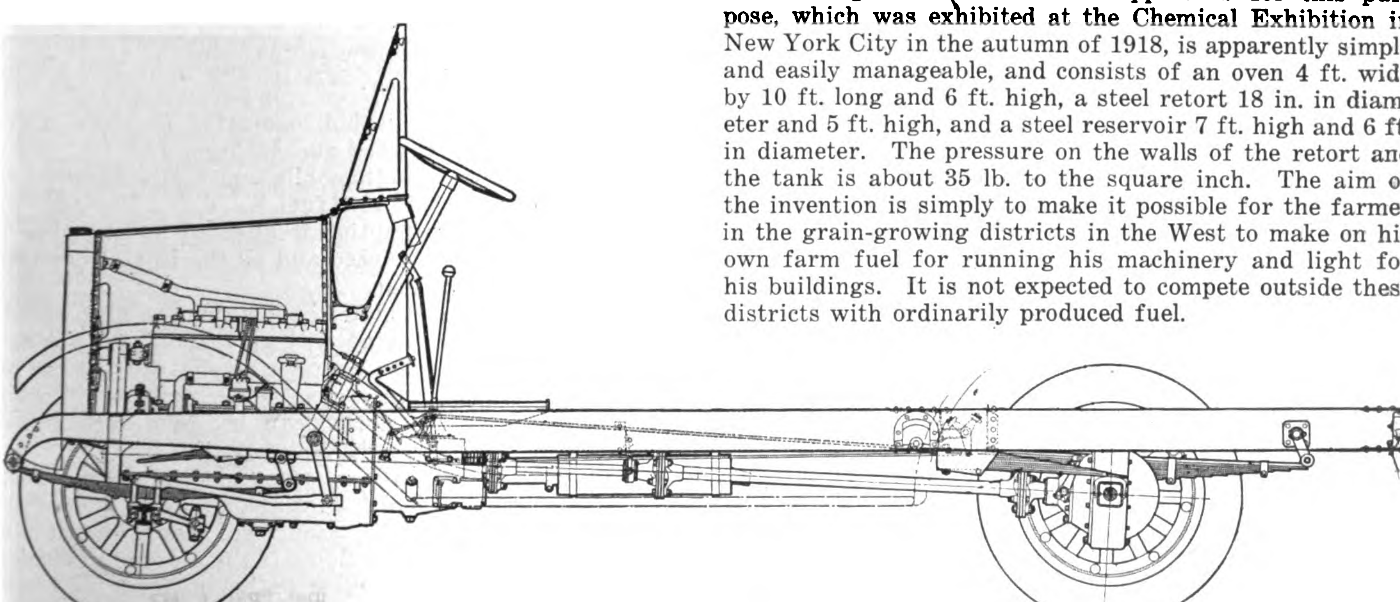
The fifth test was an obstacle test, the truck being backed up to a 6-in. curbstone, and an endeavor made to lift the rear end over the obstacle without rolling or bumping. The chain driven truck was lifted over the curb three times in succession without difficulty. The worm driven truck would not climb the curb without bounce, while the dual reduction went over without any great difficulty. In the final test the three trucks were hitched through a dynamometer to a truck anchored in the roadway, and the maximum drawbar pull which the trucks were capable of exerting was observed. Three successive attempts were made with the trucks, and the drawbar pulls registered, averaged, were as follows: Chain, 3700 lb.; worm, 2633 lb.; dual reduction, 2833 lb.

A New One-Ton Speed Truck

A NEW commercial car, designated the Akron multitruck, will be turned out by the Thomart Motor Co. It is of the speed truck type, with pneumatic tire equipment (34 x 5 in. cord) and has a rated capacity of 1 ton. The engine is a four cylinder block type, 4½ x 5 in., with force feed lubrication and three point suspension. The clutch is a dry disk type and the gearset affords three forward speeds. Unit powerplant construction is used. The propeller shaft is made up in two sections with three fabric universal joints, the central joint being supported by a floating ball bearing. The rear axle is a semi-floating spiral-bevel-gear driven type, and the Hotchkiss drive is used. The frame is of pressed steel, the channel section being 5⅞ in. deep. In addition to the primary set of semi-elliptic springs there are quarter-elliptic auxiliary springs secured to the under side of the frame channels, the free ends of which come down on the spring pressure plates when the truck is heavily loaded. The truck has a wheelbase of 133½ in. and has a speed of 30 to 35 m.p.h. It comes regularly equipped with Westinghouse electric generator and starter. A one year guarantee is given.

Motor Fuel from Straw

COMMENTING on press reports relative to the production of gas and motor fuel for lighting and power purposes from straw, the British Commercial Counsellor in Washington states that the apparatus for this purpose, which was exhibited at the Chemical Exhibition in New York City in the autumn of 1918, is apparently simple and easily manageable, and consists of an oven 4 ft. wide by 10 ft. long and 6 ft. high, a steel retort 18 in. in diameter and 5 ft. high, and a steel reservoir 7 ft. high and 6 ft. in diameter. The pressure on the walls of the retort and the tank is about 35 lb. to the square inch. The aim of the invention is simply to make it possible for the farmer in the grain-growing districts in the West to make on his own farm fuel for running his machinery and light for his buildings. It is not expected to compete outside these districts with ordinarily produced fuel.



The Akron 1-ton truck chassis

Significance of Alcohol in the Motor Fuel Problem

The probable shortage of gasoline and the limited capacity of the country for the production of alcohol and benzol renders desirable the use of a synthetic fuel containing all three constituents. Data on the characteristics and advantages of such a fuel are set forth in this article.

By Burnell R. Tunison*

THE growth of the petroleum industry has been nothing short of phenomenal, but the production of gasoline has been made to keep pace with the automotive industries, only with the greatest difficulty. The production of crude petroleum has increased about 90 per cent during the last ten years. Due to better refining methods; to casinghead gasoline; to cracking processes and other contributing factors, the production of gasoline during the same period has increased approximately 550 per cent. According to the United States Bureau of Mines during the year 1918 the production of this fuel was over 3,570,000,000 gal. and in 1919 the production was nearly 4,000,000,000 gal.

The National Automobile Chamber of Commerce states that last year the volume of the automotive business was represented by the prodigious sum of $3,166,834,600. This is surely one of our major industries involving an invested capital of over a billion dollars, employing 300,000 persons who receive annually approximately $375,000,000. There were 7,500,000 motor vehicles in use this year, or one to every fourteen persons in the country. Assuming an average motor car mileage of 3,000, the total mileage is 22,500,000,000 miles per annum. If each motor vehicle carried an average of three persons the total passenger mileage was 67,500,000,000. The total passenger mileage of all our railroads during 1919 was 46,145,070,650.

In two years the end point of the average gasoline has been raised from 392 deg. F. to 425 deg. F., or an increase of 33 deg. F.

The United State Geological Survey is authority for the statement that the petroleum resources of the country have been depleted to the extent of approximately 40 per cent, and that the remaining six and one-half billion barrels at the present rate of consumption will last only sixteen to eighteen years. But the rate of consumption will continually increase.

There is unanimous agreement among those in the automotive and petroleum industries that there is a real internal combustion engine fuel problem before us now. It is clearly evident that unless some partial solution of this problem is found the progress of the automotive industries will be seriously impaired. This would be a disastrous blow to the economic equilibrium of the nation.

Now that the problem is generally recognized, what are some of the possible remedies which may assist in its solution?

It has been said that benzol and coal tar products will assist. Even under war time stimulation the production of distillates suitable for motor fuel amounted to less than 75,000,000 gal. At present, if all these products were used as motor fuel, which is impossible because of their many other important uses, the fuel thus made available would be less than 100,000,000 gal. per year.

This article, written by a chemist connected with the United States Industrial Alcohol Co., outlines the advantages of and need for using synthetic fuel containing alcohol, and gives data regarding the performance of engines using such a fuel.

In an early issue we will publish an article by Prof. H. B. Dixon of the University of Manchester, a British authority on combustion phenomena, in which are presented the results of basic research into the properties of alcohol and its behavior during combustion when used alone and in combination with other hydrocarbons.

Alcohol has real value as a motor fuel. That it has not been a factor in America up to the present time has been due to an economic condition rather than to inherent difficulties in its use.

Some of the conclusions of the Department of Agriculture on the use of alcohol are:

1. The ordinary engine can be run on alcohol without material change.
2. When run on alcohol, operation is more nearly noiseless than when run on other fuel.
3. For air cooled automobile engines, alcohol is especially suitable as a fuel.
4. The fuel consumption is affected by the time of ignition, by the speed and by the initial compression of the charge.
5. The economy is better at low than at high speeds.
6. The average engine will give about 10 per cent more power when burning alcohol but at the expense of a greater fuel consumption. Twenty per cent more power can be developed by especially adapting the engine to the fuel.

The time is not far distant when alcohol must become a factor as a motor fuel. That alcohol cannot meet the situation at once is readily seen from a consideration of our present alcohol production. If the alcohol producing capacity of the country were to be utilized for motor fuel purposes only 100,000,000 gal. annually would be made available.

*From a paper read before the Washington Section of the American Chemical Society.

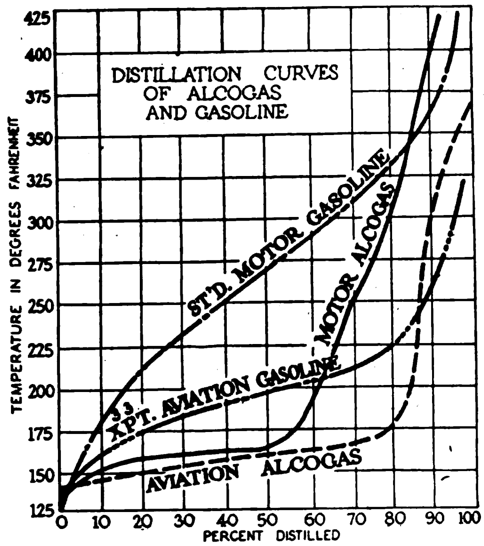


Fig. 1

The combined coal tar distillate and alcohol production of the nation would amount to less than 5 per cent of our motor fuel requirements. There is a limit to the quantity of coal tar distillates which can be produced. We have not yet realized that limit and larger quantities of coal should be carbonized in by-product recovery ovens so that these distillates will be available for motor fuel purposes.

We can and must make more alcohol. This necessity is not dependent upon natural reservoirs or deposits. We all realize that alcohol can be produced from any material containing starch or sugar. Even large quantities of waste cellulose material can be utilized for the production of alcohol for motor purposes.

The Present Solution

Knowing that no one remedy is going to be the solution of the problem, consideration should be given to the various factors contributing to it. There must be a complete co-operation between the designer and builder of automotive apparatus, the user, and the industries which supply the fuel. The designer and the builder should sacrifice power, speed and accelerating ability for efficiency. The motor car of the future should run the greater portion of the time at nearly full load conditions in order to secure the maximum efficiency. There should be material reduction in the weight of car and engine parts and a more logical proportioning of engine speed to car speed. The user should not demand high speed and rapid acceleration. He should be willing to change gears more frequently.

The producers of motor fuel should co-operate to produce a fuel which permits of higher compression ratios without the difficulties of "knock." Higher compression ratio means not only greater thermal efficiency but less weight per unit of power; and by proper design the possibility of smaller engines.

It has been conclusively demonstrated by prominent automotive engineers that the present day motor fuel is far from ideal and has very serious limitations. Efficiency is now demanded and high efficiencies are not possible with our present fuel.

Petroleum products, benzol, or alcohol when used alone are not entirely satisfactory. Each possesses distinct advantages when used in internal combustion engines. Alcohol and benzol both have certain disadvantages which will preclude their use alone in the engines of the near future. It is possible, however, to make a combination of these fuels in such a manner as to derive the natural advantages of the several components. Such a fuel including gasoline and some of the heavier distillates would indeed be a step forward.

Benzol and similar coal tar distillates possess desirable properties as motor fuels. They can be used in high compression engines and there are few detonation difficulties. In an engine cylinder benzol ignites slowly and burns in such a manner that detonation does not take place. Large quantities of carbon are formed, however, which render it undesirable, when used alone. The freezing point of benzol when not mixed with other fuels is 40 deg. F. This renders unmixed benzol unsuitable for winter use. Its use with petroleum mixtures is also undesirable inasmuch as petroleum distillates have little controlling influence over the physical or chemical properties of the benzol mixed with them.

On the other hand, it is possible to make mixtures of alcohol and benzol which show very remarkable properties. The presence of the alcohol has a marked effect on the freezing point of the mixture as well as on the formation of carbon.

Alcohol is one of the most stable fuels known, but in order to obtain best performance with it alone it is essential to use engines with very high compression ratios. The fact that alcohol has a latent heat of evaporation of 385 B. T. U. per pound as compared to 170 B. T. U. per pound for benzol and approximately 190 B. T. U. per pound for gasoline, renders it unsuitable for starting an engine in cold atmospheres. Furthermore, the low vapor pressure of alcohol as compared to other fuels makes it difficult to use in low temperatures unless blended with other components. Alcohol starts to burn very rapidly in an engine cylinder, but does not increase its rate of combustion as do the petroleum products. It can be readily seen that when alcohol is carefully blended with other fuel components which possess the qualities which it lacks, a very desirable fuel is the result.

Nearly every country in Europe to-day is seriously engaged in research work in connection with alcohol as a fuel for internal combustion engines. There is no question but that alcohol will play a very important part in the fuel of the future. The importance attached to alcohol as a fuel factor in England, France, Germany and Italy is so great that these countries are spending large sums of money to support investigations which the respective governments have called upon their best scientists and engineers to make. This work is relative to sources and processes for producing alcohol on a large scale.

Many investigators have been quick to realize the importance of alcohol as a fuel. As a result, there have been many attempts to produce satisfactory fuel mixtures containing alcohol as an important component, with the

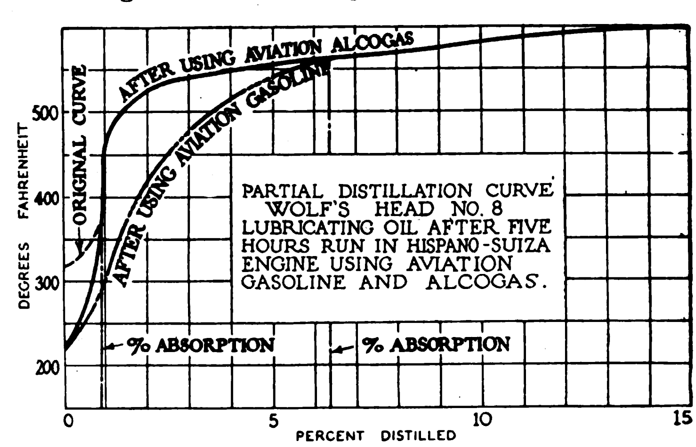

Fig. 2

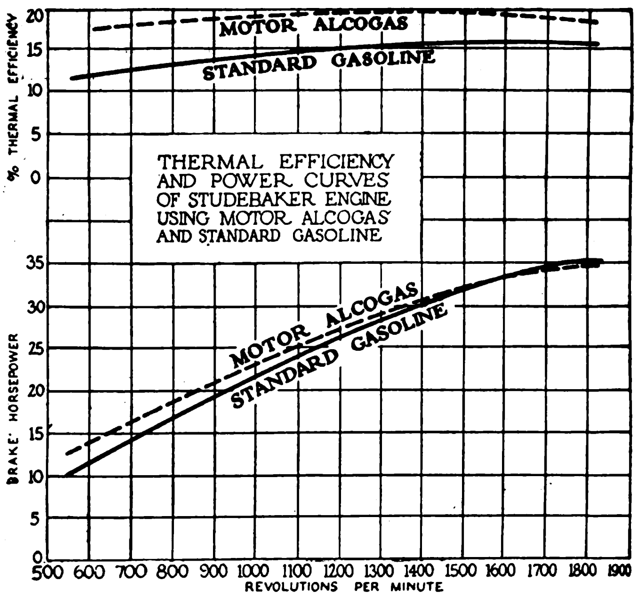

Fig. 3

hope of realizing the advantages accruing from it. In almost every case, however, these attempts have proven unsuccessful, due entirely to their impracticability or failure to meet all the present or future requirements, or both. One successful synthetically blended fuel, in which alcohol with all its advantages plays an important part is being produced in limited quantities under the trade name "Alcogas." This fuel combines among others, the advantages of petroleum distillates, coal tar distillates, and alcohol. For commercial reasons the exact formula is not given, but the components have been so chosen and proportioned that each renders the maximum assistance to the others in meeting the many fuel requirements for both present and future engine designs. The practicability and usefulness of this fuel is adequately supported by results of official tests conducted by the Bureau of Standards, the U. S. Navy, U. S. Air Mail Service, Columbia University and by the experience of many individual users of the fuel in trucks, passenger cars, marine engines, etc.

In Fig. 1 are shown the distillation curves of two grades of alcogas as compared with those for export gasoline and standard motor gasoline. It will be noted that the initial boiling point is approximately the same for all these fuels. The homogeneity of alcogas is clearly indicated by the distillation curves. In the case of the more volatile grade almost the entire volume is distilled over at the initial boiling point, while more than 50 per cent goes over at the same temperature in the case of the motor fuel. This factor is a very important one as regards crankcase contamination and oil consumption. Under actual flying tests conducted by the U. S. Air Mail Service with alcogas between New York and Washington, for a period of six months, the average oil consumption was about 40 per cent less than when using gasoline.

To determine the comparative percentage of fuel absorption by oil for alcogas and gasoline, a five-hour full power run was made with each, using a Hispano-Suiza engine, a partial distillation of the oil, before and after using being made. The results are shown in Fig. 2. The absorption in the case of alcogas was 0.9 per cent while in the case of gasoline it was 6.33 per cent. This is a very important consideration, especially as regards efficiency of lubrication and the life of engine parts and the engine as a whole.

Fig. 3 shows the fuel consumption, thermal efficiency and b. hp. obtainable on a standard four-cylinder Studebaker engine, after setting the carbureter for an air-fuel ratio to give maximum thermal efficiency. The maximum horsepower for both alcogas and gasoline is approximately the same at maximum engine speed, but the power is slightly greater at all lower speeds when using alcogas.

Fig. 4 shows the fuel consumption in pints per b.hp.-hr. for alcogas as compared with gasoline for an air-fuel ratio giving the leanest possible mixture. The mean fuel consumption for this condition is 1.00 pt. per b.hp.-hr. for alcogas and 1.17 pt. for gasoline. This represents a saving of nearly 15 per cent.

The following table shows the limiting conditions of mixture for alcogas and gasoline.

Table of Air-Fuel Mixture Properties

	Gasoline	Alcogas
1. Richest mixture on which engines will operate over the speed range employed	9.7	9.15
2. Leanest mixture on which engines will operate over the speed range employed	14.9	16.0
3. Chemically correct ratio	14.7	12.3
4. Per cent of air chemically required present in 1	66	75
5. Per cent of air chemically required present in 2	102	130
6. Ratio for maximum power	13.2 to 11	12.5
7. Ratio for maximum efficiency	14.9	16
8. Per cent of air chemically required present in 6	90 to 75	102
9. Per cent of air chemically required present in 7	102	130

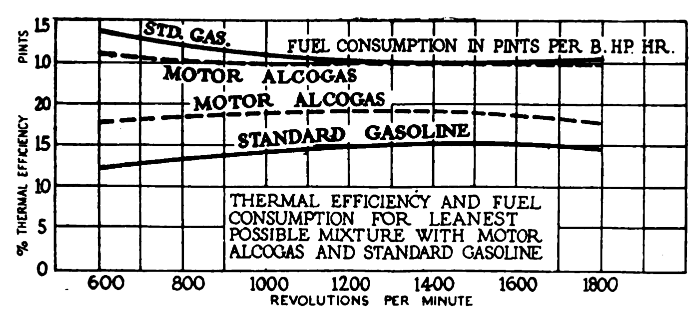

Fig. 4

From the above it will be noted that gasoline has practically no range on the lean side of the best mixture, while with alcogas the range is about equally divided, the total being over one and a half times as great as for gasoline.

From the above discussion it is evident that alcogas is an entirely practical fuel meeting the requirements of present day engines besides possessing many very important advantages. Probably its most important advantage is its applicability to the very high compression engines of the future.

In Fig. 5 are shown the results of tests made by the Bureau of Standards on a standard Liberty engine using alcogas at various altitudes up to 25,400 ft. The engine was equipped with special pistons to give a compression ratio of 7.2 to 1. The curves show the increase in power and economy resulting from this compression ratio as compared to a ratio of 5.6 to 1.

Conclusions

Alcogas is only one of the many blended fuels proposed to aid in the solution of our motor fuel problem. No synthetic fuel will probably be the ultimate solution

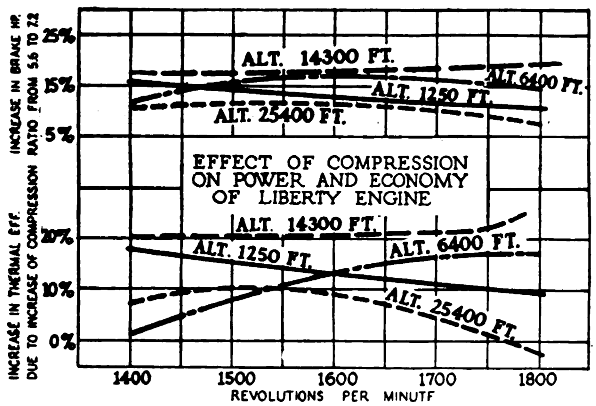

Fig. 5—Fuel used, Alcogas

of the problem, but they will all assist in postponing the day when we can no longer depend entirely upon petroleum resources.

In engine design, construction and use it is impossible to jump from the present day petroleum fuel to alcohol. Blended fuels can be efficiently and effectively utilized in present day engines and will meet existing requirements. Future developments will very probably take the direction of slower speed engines, higher compressions, longer stroke, etc., which are the qualities required for the efficient utilization of alcohol fuels.

In the near future it is hoped that this country will emphasize and encourage the production of alcohol for motor purposes as well as the use of blended fuels so that when the day approaches when our petroleum resources are exhausted, we shall have ample capacity for the production and utilization of fuel alcohol.

Petroleum

THE production of petroleum involves a higher proportion of waste than is found in the mining of coal, with far more serious consequences because the domestic supply is altogether inadequate for meeting the present requirements of the country and the domestic resource is rapidly suffering depletion. Less than half of the oil underground is raised to the surface; there has long been an overproduction in respect to the higher types of uses, prompting the surplus to be used for crude purposes in the place of coal and water power. The responsibility for these conditions lies with the small-unit competitive type of mining prevalent in the United States, whereby the geologic unit or pool is arbitrarily divided into many small holdings separated by vertical boundary planes. Petroleum is a migratory mineral, moving underground in the direction of lower pressure, and hence each individual producer is forced to race with his neighbor for the extraction of the product. Thus not only is production in each new field quickly forced beyond the handling facilities of the moment, but much of the oil underground is permanently placed beyond reccvery by this discordant type of production. There is a drift toward commercial integration and individual co-operation in petroleum mining, but with insufficient rapidity in view of the resource size.

The transportation of petroleum makes use of an extensive system of pipe lines, thousands of miles in length, spread over half of the country, connecting points of production with refineries, markets, and seaports. The efficiency attained in the transportation of petroleum energy is in marked contrast to that characteristic of coal energy and should point the way to the reconstruction of the latter, whose faults are now throttling the commodity transportation of the country as well as contributing to unhealthy urbanization and sectionalization.

The utilization of petroleum is far in advance of coal in that the bulk of crude petroleum now produced is separated into its chief components—gasoline, kerosene, fuel oil and lubricants—whereas coal is employed dominantly in the raw state. Here again the oil industry points to the analogous need for a coal refining industry to separate coal into mobile forms of energy and commodities. The utilization of the various petroleum products displays various degrees of efficiency, with the greatest discount applying to the low-use products such as fuel oil. The by-product actualities held in petroleum are not yet adequately utilized, nor are the by-product potentialities sufficiently developed. The most important immediate problem in connection with petroleum utilization is involved in the rapidly mounting demand for motor fuel, a circumstance requiring a rapid diversion of fuel oil from its present rôle of steam-raising fuel to that motor fuel—a change which may be brought about by a co-ordinated development of cracking methods of distillation and adaptations on the part of internal combustion engines to a lessened dependence upon volatility. The adequate growth of automotive transportation on land and sea and in the air would seem to be involved in the successful handling of this issue.—*From a paper by C. G. Gilbert and Joseph E. Pogue presented before American Society of Mechanical Engineers.*

The Havre-Paris Pipe Line

FOR the purpose of delivering petroleum from Havre to Paris, a pipe line 126 miles long is being constructed for the Compagnie Française de Transport des Mazouts et Petroles. Except for one-tenth of the distance the line will follow the Route National from Havre to Paris. The pipe, which is to be 10 in. in diameter, is to be laid along the edge of the road 3 ft. below the surface. At Havre and Paris there will be ten tanks of a capacity of 55,000 barrels each, and six tanks of a similar capacity will be stationed along the route at the pumping stations. The latter will be provided with apparatus for heating heavy oil so that it may flow easily.

An interesting point in the plans for construction is that arrangements have been made to utilize trench-digging machines, which were sent to France for the American Army, and were taken over by the French Government when the latter acquired the American Army stores. The pipes, tanks and pumps required for the undertaking are being sent from America.

THE Society of Motor Manufacturers and Traders (Great Britain), has voted a sum of $125,000 (nominal exchange) for the formation of a fund to be known as the "S. M. M. T. Trust Fund" which will be used for the purpose of granting relief to persons considered eligible as having contributed to the encouragement, promotion, or protection of the motor trade. In addition, the Society has voted a further sum of £5,000 to the Cycle and Motor Trades Benevolent Fund, bringing the total contribution of the Society to that Fund to nearly £14,000.

Steel Spoked and Disk Wheels Popular on British Cars

Wire wheels still favored for high grade cars but wood wheel is almost extinct. Pressed steel spoked type used extensively on small medium priced cars. Several types of disk wheel employed. Corrugated disks are hard to clean and are being abandoned. Demountable rims uncommon.

By M. W. Bourdon

ON British cars the wood type of wheel is practically extinct, for only one or two makers will use this type in 1921. The wire spoked wheel is still favored for high-grade cars, the principal makers of this type being Rudge-Whitworth and Dunlop, both of whose designs are probably well known in the United States.

Unquestionably the most popular type of wheel for small, medium priced cars is the pressed-steel hollow-spoked variety, of which Sankey was the originator. The Sankey wheel consists essentially of two pressings, each forming half the rim, spokes and hub, these being welded together at the vertical center line. There is one other part, however, consisting of a unit which forms lateral webs in the spokes, which is inserted between the halves before they are welded together. The hub of the complete wheel is drilled for tubular distance pieces, through which pass the threaded studs holding the wheel to the hub in casting by means of exterior nuts, this being the favored method of fastening detachable wheels of this variety.

Some few failures of the Sankey wheel are said to have occurred through the tire pressure separating the two portions of the units forming the rim. This shortcoming is made a great deal of by a competitor who has entered the field against Sankey, namely Goodyear (no connection with the Goodyear Tire Co.). To overcome this drawback Goodyear welds a complete rim between two steel pressings resembling those of the Sankey.

Detachable flange rims are comparatively rare in England, though there is one well-known popular make, the Warland. This has a detachable flange secured by bolts, but this flange merely locates a transversely split rim with a loose segment which can be removed and the ends of the main portion drawn together for easy fitting or removal of clincher tires. Sankey has, however, recently introduced a detachable flange rim for a wheel of the pressed steel hollow spoked variety, the method of construction otherwise being identical with that of his original pattern.

A novel type of wheel construction is that introduced by Smith-Parfrey, originally wood wheel builders. It is

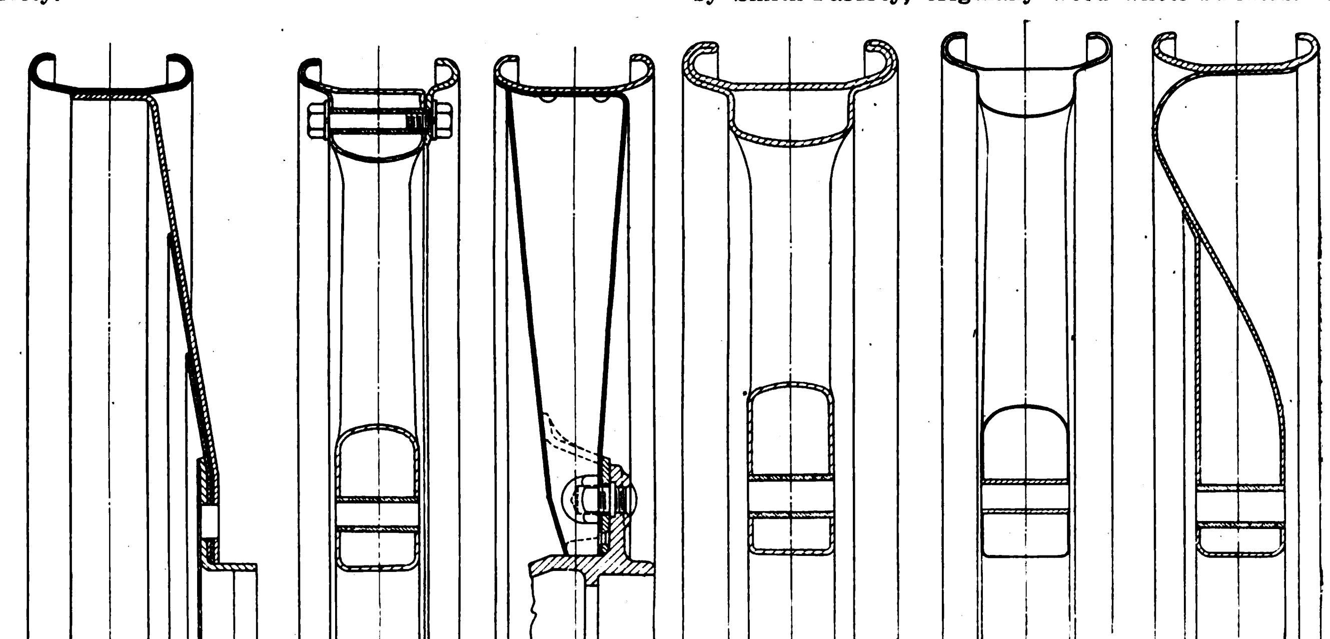

Fig. 1 *Fig.* 2 *Fig.* 3 *Fig.* 4 *Fig.* 5 *Fig.* 6

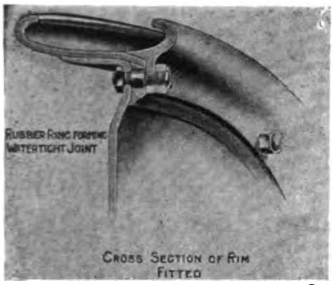
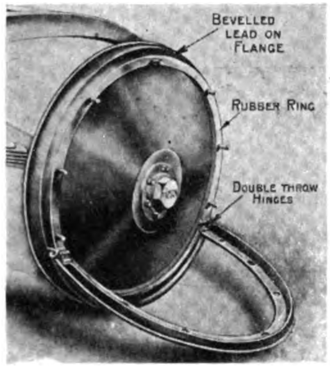
Fig. 1—The Riley laminated disk wheel. Fig. 2—The Sankey hollow spoked wheel with detachable clincher flange. Fig. 3—Section of the Goodyear corrugated disk wheel. Fig. 4—Section of the Sankey pressed steel hollow spoked wheel, which consists of two units welded at the center line. This is the original of its type. Fig. 5—The Goodyear pressed steel hollow spoked wheel, which has a separate and complete rim welded between the two units forming the felloe, spokes and nave. Fig. 6—Part section of the Sankey dual disk wheel. This is used by some makers with the flat surface outward, though the curved surface is normally intended to form the exterior



Section of Rapson hinged flange rim and disk wheel



Rapson hinged flange rim and disk wheel

built up, as shown in an accompanying sketch, of flat steel plates shaped at one end so that the combined units form the hub, the outer ends of the spokes being riveted and welded to a rim base of flat section. Strength for weight, there does not seem any advantage in this system, nor does it present any benefit in cleaning. It is put forward for both cars and trucks.

In regard to disk wheels, these are gradually becoming more popular with both makers and users, and not infrequently wire spoked wheels are enclosed by detachable aluminum disks. Two car manufacturers make their own disk wheels, namely Armstrong-Siddeley and Riley. The first named has attached to the rim by welding and riveting a disk with a very large hole in the center, the inner diameter of the disk in the case of rear wheels overlapping the brake drum and being secured to it by studs and nuts. In the case of front wheels the disk is bolted to inner disks secured to the hub.

Riley has a laminated disk built up of three disks increasing progressively in diameter. All are secured to the wheel hub, but only the larger one extends to the rim, where it is spot-welded. The laminations are also spot-welded together. The Riley design somewhat resembles the Michelin, except that the latter has a single disk tapering in section.

Sankey is making a disk wheel for quite a number of car manufacturers, but this is a dual disk, as shown in the section herewith, the main unit extending from hub to rim and being considerably dished toward the center. At the back of the main disk there is a second, flat-surfaced disk, welded to the other, the two together forming a hub varying in width according to size of wheel as a whole.

The Goodyear wavy disk wheel, which first came into prominence when it was adopted for Angus Sanderson cars in 1919, has not found a great deal of favor, and, although it is being continued, the makers are shortly introducing a flat disk type. It has been found that the wavy disk, as might have been expected, is almost as difficult to clean as a spoked wheel, and while it fails to present any advantages in that respect, it certainly has none in appearance, the corrugations giving a distinctly clumsy effect, both when the wheel is stationary and when running.

Another make of disk wheel is the Lynton. This has a flat disk of uniform thickness offset from the rim center and is riveted and welded to the tire rim. Lynton has for many years past made a disk wheel consisting of two plates, between which the tire rim is clamped. The inner plate is fixed to the hub, the outer one being detachable, thus providing a demountable rim effect.

Dunlop has recently introduced a corrugated disk wheel, but it is considered doubtful whether this will obtain any popularity. Although it probably is considerably stiffer than a flat disk, the multitude of corrugations is a distinct disadvantage in the matter of cleaning. A separate hub plate, to which the corrugated disk is welded, is used.

Rapson has recently put forward a disk wheel with two-thirds the rim flange hinged to the remainder to facilitate tire manipulation. This is shown in perspective and in section in accompanying illustrations.

Although the vast majority of British wheel makers specialize entirely upon wheels and rims for clincher tires, the possibility of straight-side tires being popularized in the near future has not been overlooked, and Dunlop, for example, is making the new corrugated disk wheel for both clincher and straight-side tires. There has, however, been no indications of any great move toward straight-side tires by British car makers or users.

A point in favor of the disk wheel of the single disk type is that it allows the point of tire contact with the ground to be more easily brought under the axis of the steering pivot. Armstrong-Siddeley, Riley, and one or two other makers have taken advantage of this, fitting vertical pivots immediately over the point of tire contact. Users confirm the claim for peculiar ease of steering and freedom from shock, even when compared with steering lay-outs having inclined pivot pins with their prolonged axes extending to the tire contact centers.

A New Type of Piston Ring

A PISTON ring of unusual construction has recently been designed and tested by Harry B. Johnston of Seattle. The ring is approximately triangular in section and but two rings are used per piston. The cylindrical face of the ring fits the bore of the cylinder. A second face at right angles to the axis of the piston is disposed toward the head of the piston in the case of the upper ring, and toward the skirt in case of the lower ring. The third face is inclined at an angle of 35 deg. and fits against a correspondingly inclined surface of the groove. The ring is given only a slight spring to hold it against the cylinder wall, but the pressure existing in the combustion chamber is admitted to the spaces between groove and ring, thus forcing the ring against the cylinder wall to maintain a gas-tight joint. The wedging action of the tapered face of the ring against the inclined face of the groove is said to increase the effectiveness of the seal. It is claimed for the ring that it effects an increase in power development as compared to conventional rings and prevents oil pumping as well as leakage of fuel into the crankcase of the engine.

Piston ring depending chiefly on gas pressure to maintain seal

Three Post-War Wolseley Chassis

Two are four-cylinder models of 10 and 15 hp. respectively, and the third is a 20 hp. six-cylinder model of earlier design but somewhat modified, and of quite different design from the fours. The "Fours" have overhead camshafts with blade-spring drive. Battery ignition is standard.

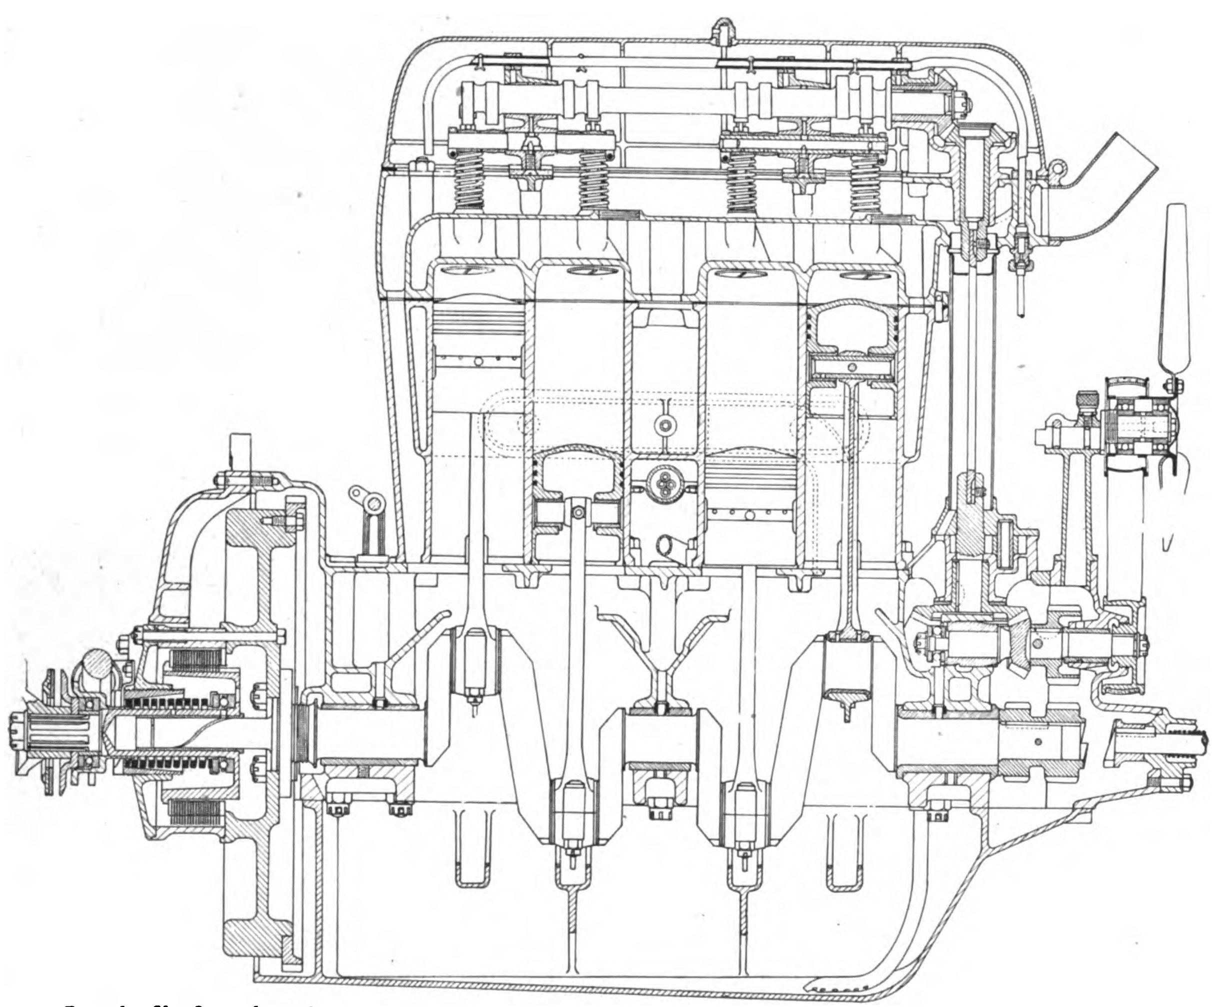
By M. W. Bourdon

THE three units of the post-war Wolseley range were shown at last year's Olympia Show and created a large amount of interest, but production and other difficulties prevented deliveries being commenced until quite recently in respect of the two smaller types, though the six has not been so belated.

Chief interest attaches to the 15 hp. model, made for four passenger bodies. It departs in almost every detail from pre-war Wolseley practice, has a high efficiency overhead camshaft engine and the complete chassis form weighs only 1800 lb. The special features of the engine are embodied also in the smallest model, a light runabout with a four-cylinder engine having a bore and stroke of 2 9/16 x 3¾ in. and being one of the best finished and best sprung of its type on the road. Its selling price is now $2,700 complete.

The 15 hp. chassis has, then, a four-cylinder 80 x 130 m.m. (3⅛ x 5⅛ in.) engine with a detachable head carrying the camshaft and valves. The cylinder block is of cast iron, and is bolted to the top part of the aluminum crankcase. The camshaft (like the crankshaft) is carried in three bearings and has the valve rockers pivoted on a shaft immediately below it, the cams applying to projections on the rockers situated midway in the length of the latter; the rockers are, in fact, of inverted T shape with the cams applying to their single member.

A somewhat involved form of drive is used for the camshaft. First there is a silent chain which runs on three sprockets, on crankshaft, water pump shaft and countershaft respectively. The countershaft carries a bevel pinion meshing with another pinion at the lower end of the vertical drive which latter carries just above the bottom



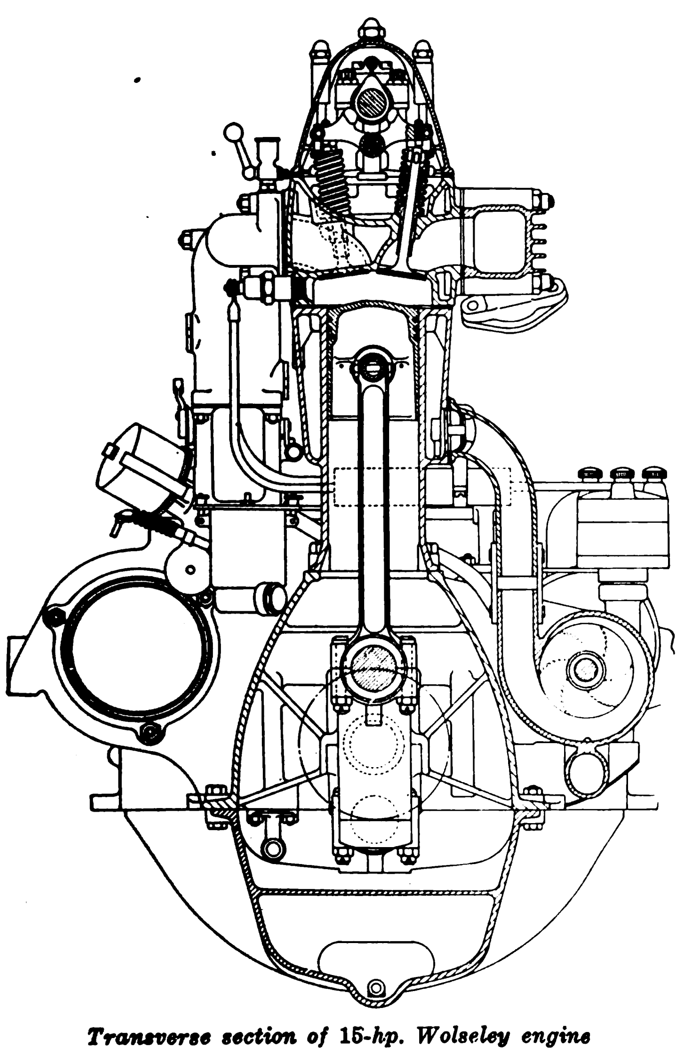
Longitudinal section of Wolseley 15-hp. (3⅛ x 5⅛ in.) engine, showing spring blade camshaft drive

bevel pinion the primary gear wheel of the oil pump. At the upper end of the driveshaft another bevel gear meshes with one on the front end of the camshaft. A special feature is a spring blade coupling 7 in. in length between the separate upper and lower ends of the drive shaft, the object being to afford a certain amount of flexibility in the camshaft drive to induce silent valve operation.

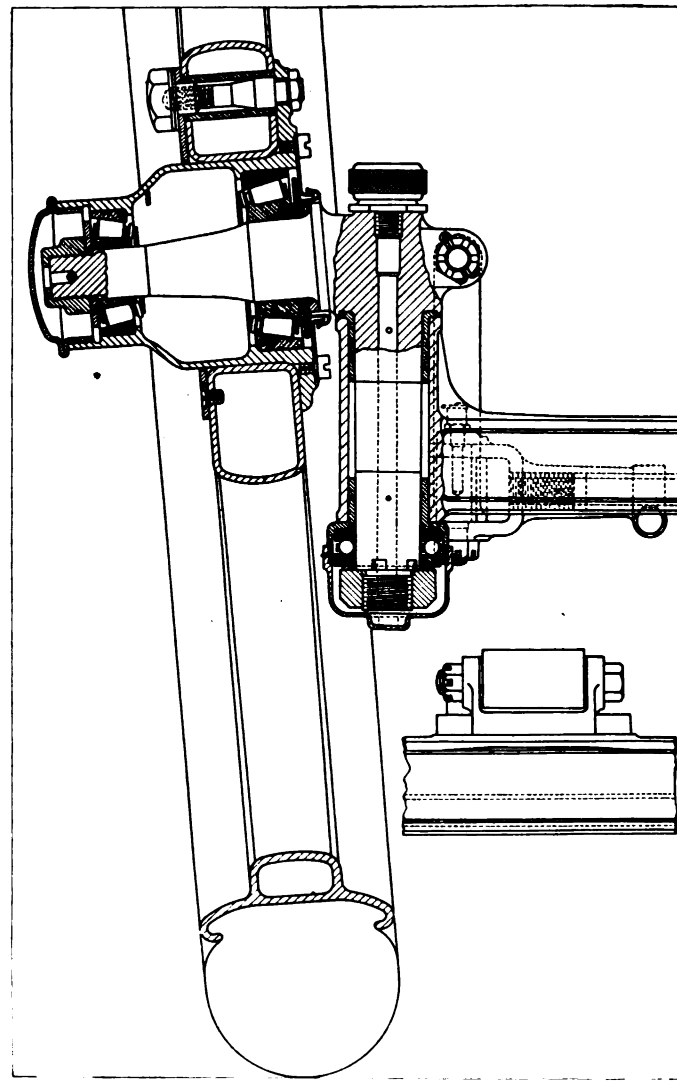
Dynamo-battery ignition is standard, but most of the chassis delivered hitherto have had magneto ignition. Whether magneto or dynamo be used (the latter as a unit with contact breaker and distributer), it is driven by a rearward extension of the water pump shaft on the left of the crankcase, the spark plugs being on the right and the cables passing across through a tunnel in the center of the cylinder block at the lower end of the barrels.

Lubrication is on the trough system for the connecting rod bearings and pistons, but large catch pits are formed over each main journal and oil is fed directly into these. The aluminum pistons have three rings with the hollow piston pins floating in bronze bushes in the bosses, the pins being fixed in the connecting rod small ends by ¼ in. bolts passing right through. From the oil pump, a copper pipe leads to the camshaft bearings and from the latter oil runs through drilled holes in the brackets to the bearings of the hollow rocker shaft and to the rockers themselves. Surplus oil returns to the crankcase through an external pipe at the rear end of the head casting and through the tube enclosing the vertical driveshaft at the front. Provision is also made for a direct oil lead to the silent chain and to an indicator on the instrument board.

There are separate exhaust and inlet manifolds on the left and right respectively of the head casting, the carbureter with vacuum feed being a Wolseley edition of the S. U. bellows pattern. A claim of a fuel consumption of 30 miles to the Imperial gallon is made.



Transverse section of 15-hp. Wolseley engine

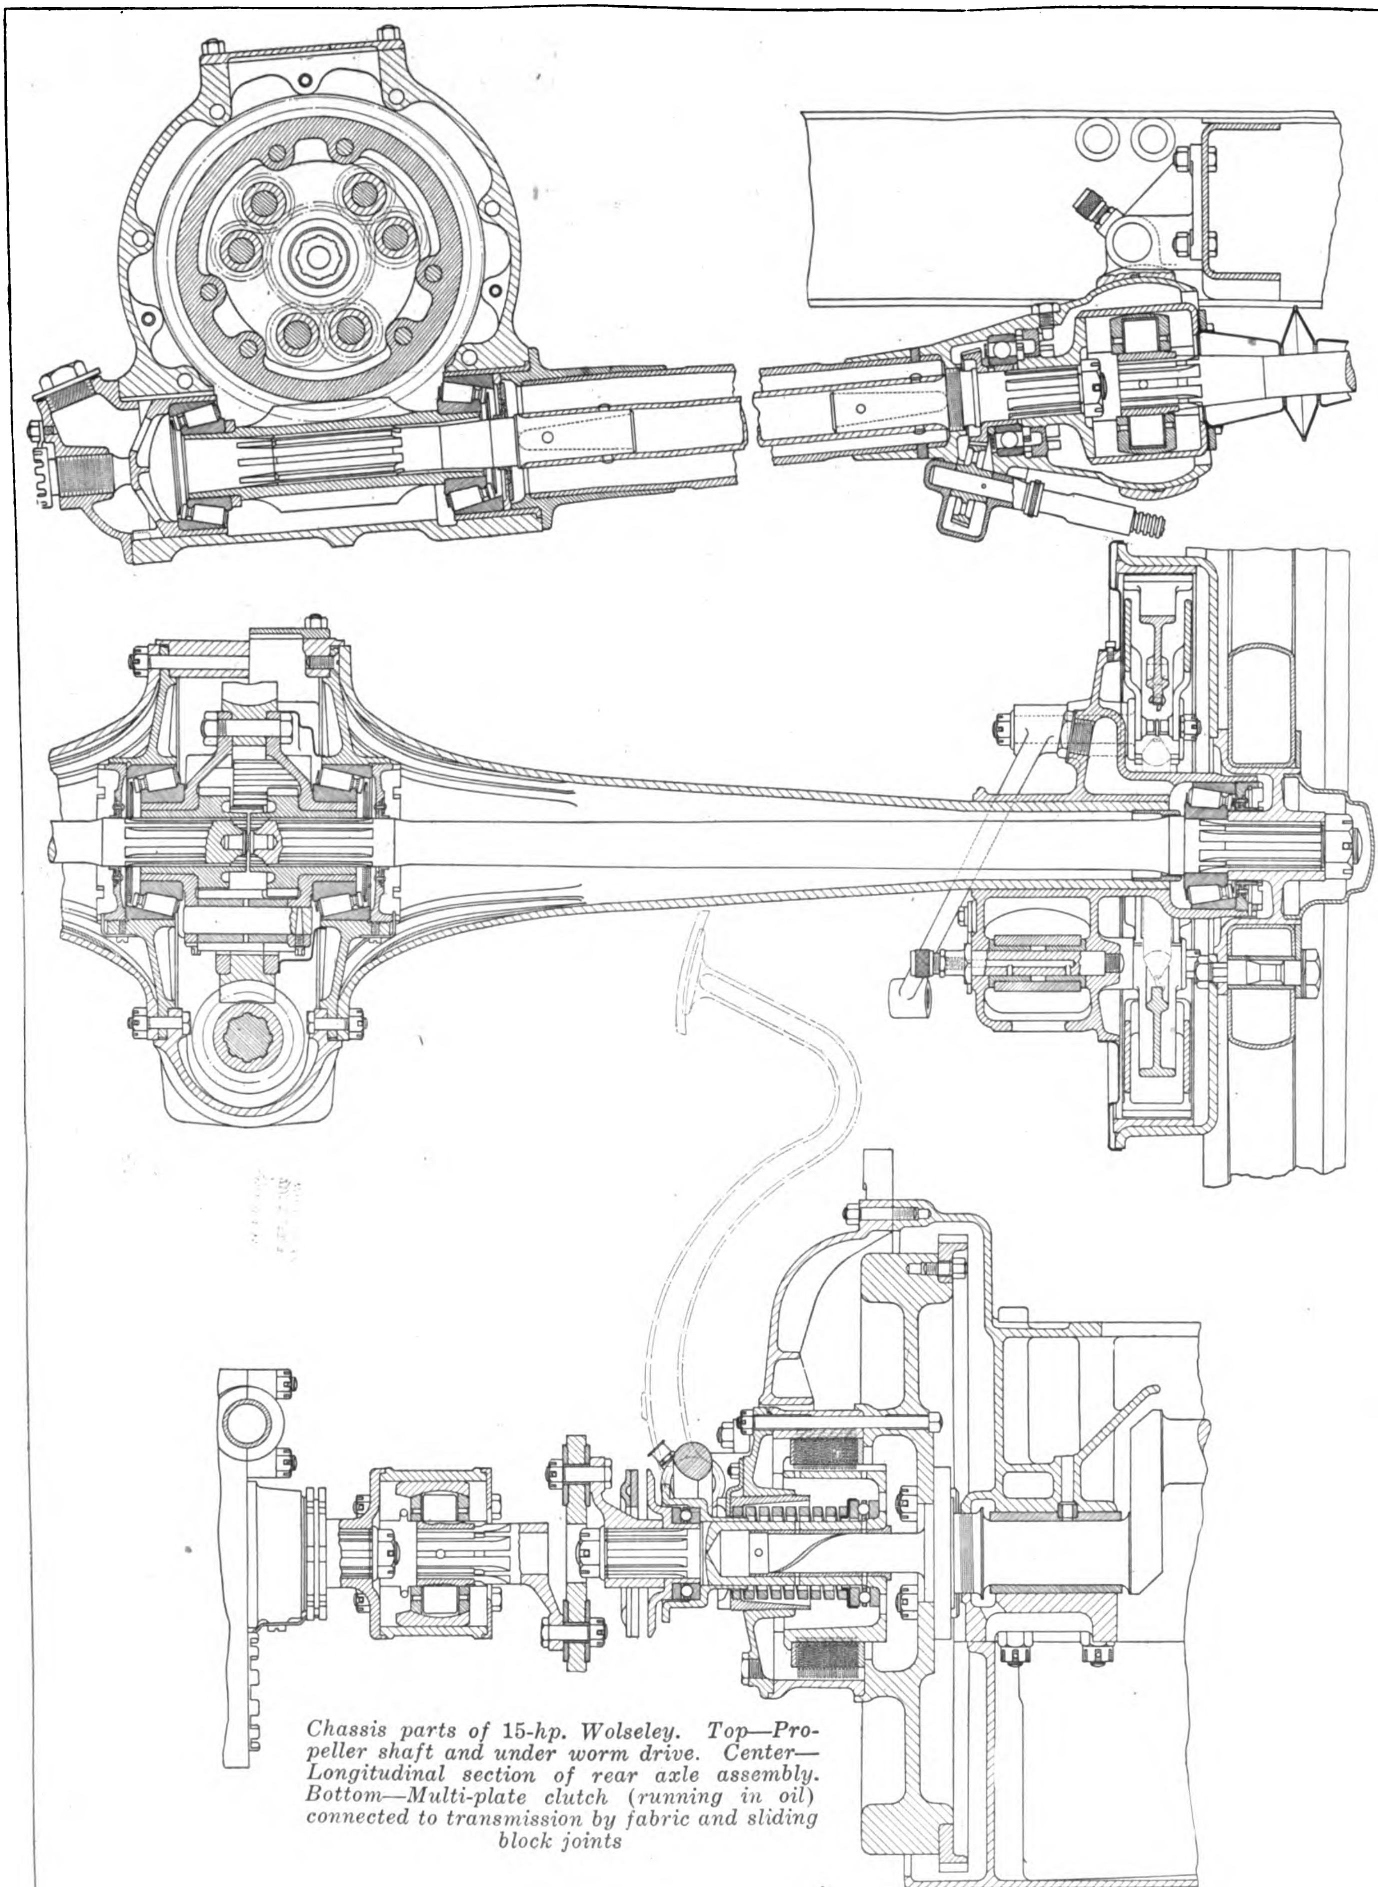


Wolseley front wheel and ball-thrust steering knuckle

The flywheel is completely enclosed, its casing supporting the starting motor alongside the right of the crankcase, which is carried by four arms extending to the main frame. A multiplate clutch running in oil is used, with a coupling shaft having sliding block and fabric disc joints. The three-speed gearset with right hand control is supported by tubular and pressed steel cross members, at one point from the former in front and at two points from the latter. Behind the gearset a short exposed coupling shaft with a fabric disk point at the front end leads to the enclosed sliding block type universal at the head of the propeller shaft, the latter being enclosed in a torque tube with a spherical mounting slung below the center of a pressed steel cross member.

Under-worm drive (4.8 to 1) is used in the rear axle, which latter has an aluminum center with tapered steel extensions. The axle is of the non-floating type with Timken roller bearings throughout, this type of bearing also being used in the gearset, except for the pilot, which has a plain bush. Front wheels also run on Timkens with a ball thrust for the steering pivots.

Both sets of brakes apply within the 14 in. wheel drums of pressed steel, the latter having steel rings shrunk into them to provide a wearing surface. In each brake drum there are four segments in the same plane, opposite pairs being actuated by hand lever and pedal, the shoes all being 1¾ in. wide.



Chassis parts of 15-hp. Wolseley. Top—Propeller shaft and under worm drive. Center—Longitudinal section of rear axle assembly. Bottom—Multi-plate clutch (running in oil) connected to transmission by fabric and sliding block joints

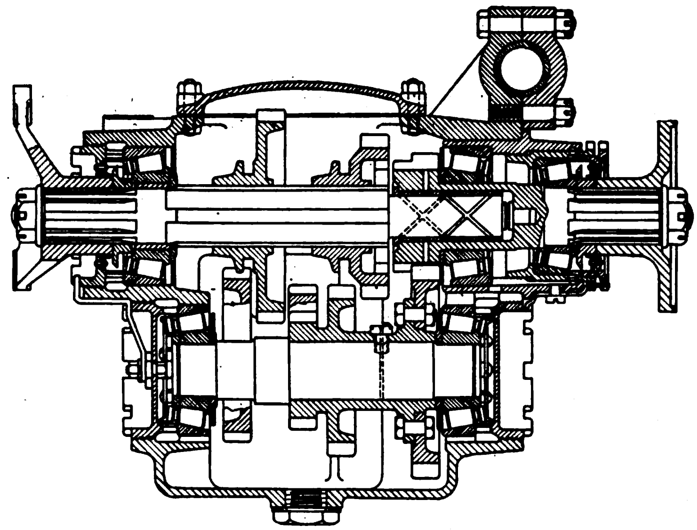
Another special feature (for a car of this size) is the use of quarter elliptic springs, these having been tried out on the 10 hp. model in pre-war times with great success.

The steering is of the worm and worm wheel type, the housing being mounted on the front arm of the crankcase on the right with a transverse drag link to the left hand swivel lever. Pressed steel hollow spoke wheels are standard with 815 x 105 mm. (32 x 4 in.) tires, the wheelbase being 118 in. and the track 52 in.

With its standard type four-passenger open body and the usual full equipment, the 15-hp. Wolseley sells at $4500, and it is currently reported that a substantial increase may occur in the near future.

The principal point wherein the 10-hp. model differs from the 15-hp. is that it has its three-speed gearset as a unit with the worm driven rear axle. Originally it had a unit cast cylinder block and crankcase; but these are now separate, the latter in aluminum.

In almost every main detail the 20-hp. six-cylinder is different from the 15-hp. It has its cylinders cast in threes with integral L heads, magneto ignition, four-speed gearset, transmission brake, open propeller shaft, cantilever rear springs and wire wheels. Where it bears resemblance is in the trough system of lubrication, aluminum pistons, vacuum feed, multiplate clutch, amidships position of gearset, and worm drive. It weighs 2460 lb. (chassis only), has a wheelbase and track of 138 in. and 54 in. and sells at $6300 with a five-passenger body.

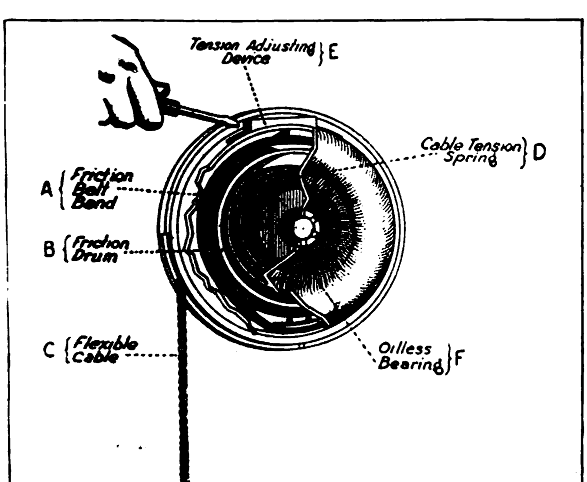


Three-speed gearset used on 15-hp. Wolseley

A Friction Band Shock Absorber

A SHOCK absorber acting only on the recoil of the spring is manufactured by the Gilman-Davis Mfg. Co. An adjustable friction belt band engages with a friction drum and any tendency of the body and the axle of the car to suddenly separate, causes a sufficient tightening of the friction belt band upon the drum to counteract the thrust and retard the upward movement. This result is accomplished by the frictional contact between the free end of the band and the drum and by the forward movement of the opposite end of the band by the rotation of the drum.

On the other hand, when body and axle approach each other, the tension of the flexible cable is released and the spring is permitted to return the drum. Coincidently the friction between the free end of the friction belt and the stationary drum, co-operating with the reverse movement of the opposite end of the band, loosens the band sufficiently to allow the drum to be returned by the spring. The tightening and the release of the friction belt band are automatic at the beginning of each forward or reverse movement of the drum. Adjustment of the band tension can be made with a screw driver.



The Gilman shock absorber

Repairing the Ford

THE Ford automobile is in such universal use and there are so many of them to be found that the business of repairing them assumes gigantic proportions. J. Howard Pile, in his recently issued book, "Modern Methods of Ford Repairing" (U. P. C. Book Co., New York), describes methods and tools which will facilitate the standard repairs. Competition is so keen and the margin of profit so small that the work must be done efficiently or the profits will turn to losses.

In the compilation of this service manual, the author has studied factory and shop methods from many angles, and the reader is given the benefit of observations covering many of the most profitable and efficient Ford service stations in the country. This material was first published in a serial in Motor World, but it has been revised and brought up to date and there is considerable material in the book that did not appear in serial, such as wiring diagrams of all the starting and lighting systems that were put on the Ford car before the FA starting and lighting system became standard equipment.

The size of the book is such that it can be carried in the pocket, the pages being 6½ x 4½. Beside the twenty-four wiring diagrams, there are 135 illustrations of special tools, equipment and devices and the pages run to 251, including a complete index of all operations and subjects.

British Production Methods Show Improvement

Many British manufacturers have made a decided improvement in their production methods, but there are still a number of high-priced, low-value cars on the market. In the British automobile industry it is considered discreditable to use stock parts. It is the general opinion that every self-respecting manufacturer must make all component parts of his cars.

By M. W. Bourdon

THERE are still a number of British firms who have not departed appreciably from their pre-war designs, and among these may be mentioned Sunbeam, Vauxhall, Arrol Johnston, Daimler, Rolls Royce, and Star. But such firms have not, up to the present, experienced any difficulty on that account, for they have sold all the cars they could make on the excellence of their reputations, and at any price, within reason, they have cared to demand.

But with increasing competition from makers who have thoroughly up-to-date designs which, in many cases, such as Austin, Crossley, Angus Saunderson and especially the new 18-hp. Phœnix, which is an excellent production job, have resulted or will result in reduced costs of production, the hands of the more conservative manufacturers will probably be more or less forced in the not far distant future. As supply continues to gain on demand the prospect of the pre-war standards of design being more generally superseded becomes nearer at hand, for there is plenty of scope for closer co-operation between designer and production engineer.

No surprise will be felt if before this time next year there is introduced the true post-war models of certain of the firms which are still making merely a modified pre-war car. The home market will before long approach the present saturation point so far as some of the comparatively high priced (or low value) cars are concerned, and if their makers are to keep their heads above water they will have to produce designs more adaptable to economical production. In his tours through some plants the writer has been astounded at the lack of evident endeavor to simplify design from the production standpoint.

The policy frankly adopted by one maker, if not actually advocated by him, of "letting buyers do the testing" of new models is not general; nor is it singular—unfortunately for both maker and user. Unfortunately for the latter for two reasons, one of which is obvious but the other not so clear. This policy may enable production of new types to commence earlier than would be the case if the experimental chassis were put through prolonged tests, but it cannot surely be so economical in the end; it has, in some cases, to the writer's personal knowledge, involved serious alterations to or replacements of patterns, jigs and special tools, and these must clearly be paid for by someone—if not by the maker, then by buyers.

Wolseley, Armstrong, Siddeley and a few others who introduced post-war chassis at the 1919 Show have been objects of contumely in some quarters for not having commenced deliveries until so many months later. But there has been "method in their madness" which should be to their subsequent advantage, even though they have lost immediate benefit.

Doubtless many who rushed deliveries of post-war chassis not thoroughly tried out were encouraged to do so by the need for revenue to keep plants going and by the clamoring of the public for new cars last year and until the end of the past summer. The former has indeed been a spur in some instances, but one that has been ineffective nevertheless, and as a result financial difficulties are being experienced in some quarters, while rumors of troubles to come are by no means infrequent and not always ill-founded.

Some if not a large proportion of the new firms who rushed into the automobile industry for the first time last year are currently reported to be *in extremis*, and although in certain instances the trouble has arisen from difficulty in obtaining material, from the molders' strike and from labor difficulties in general, in others it has developed from faulty design, bad organization and a lack of experience.

There is, therefore, in prospect a "weeding-out" of unstable concerns, not necessarily brought about by a "slump," but by mismanagement, unjustified optimism, lack of capital at the outset, or any combination of the three.

Multiplication of Models

It is to be noticed that a few British firms have changed their pre-war policy of endeavoring to cater for many markets with several models of different sizes. But the plan of specializing on one type has by no means received general approval as the following will show:

Daimler has three models, two with identical engines and gearsets but differing appreciably at various points of the chassis; the third with a larger engine and a heavier type altogether.

Star has two models issuing from one plant and two more from an allied and adjacent factory.

Humbers have three models, and though two are identical in engine and gearset they differ almost everywhere else; the third is entirely different.

Vauxhall has two models with different engines and chassis, but not entirely dissimilar, one being a "general purpose" model and the other a high efficiency sporting type.

Vulcan has three, two somewhat alike and the third bearing no resemblance.

Wolseley has three, all different, though two have the same system of overhead valve operation on engines of entirely different dimensions.

In addition, Daimler, Star and Vulcan produce truck chassis, the first and last one model each with detail variations, and Star three models.

Divergencies in Detail

As briefly indicated, in many cases where more than one model is produced there is very little opportunity—nor is there much endeavor—to make either main or subsidiary units adaptable to the different chassis. We find chassis with both unit power plants and separate gearsets issuing from the same maker; subframes and no subframes; cone and disk clutches; right-hand and central gear controls; vacuum and gravity fuel feed systems; magneto and battery ignitons; L head and overhead valves; open and enclosed propeller shafts; and so on indefinitely. It seems as though some firms cannot make up their minds as to which alternative in each case is the better, and though it is apparent that one system of construction in a particular part may not be suitable for two entirely different chassis types, that is not always, by any means, accountable for the divergent practice.

It will be accountable to most people, for example, why Daimlers fit a honeycomb radiator with the filler inside the bonnet on one model and a tubular radiator with a normally positioned filler on another model, both having identical engines; why they use two ball-bearing star universals on the propeller shaft of one of these cars, and a block and star at front and back respectively on the other. It cannot be said that one model is an earlier type than the other and therefore does not embody the latest approved practice. This is doubtless the reason in a few instances, but it does not hold good in the majority; it would certainly seem that there is only too frequently no endeavor to cheapen production by utilizing identical parts where possible for two or more models.

High Standard of Performance

But despite all the foregoing, British cars and British production methods are improving, there can be no question of that. Whether they are improving as fast as they might is another matter. The established British maker is, at least, far-seeing in one respect, if not generally; he is not attempting to turn out cars that he has reason to believe will do him no credit. He may adopt designs bad from a production standpoint and he may get down to production in his limited way (judged by American standards) without giving his new models a six or twelve months' testing; but, with a very few exceptions, he will not allow immediate gain by shoddy work to jeopardize his reputation. Nor will he "design down to a price" without consideration for his future interests.

In most branches of engineering the British manufacturer is inclined to be conservative, but it is only fair to give him credit for turning out "good goods" when he does adopt a new design or accessory. So the British automobile engineer usually sets himself a fairly high standard in engine efficiency, workmanship and finish. Most of his customers buy cars to keep and use for many years. Eighty per cent, too, take pride in the appearance of their cars, externally and under the hood, and therefore expect a finish which will do them credit. They like individuality to a certain extent, and therein the British maker gives them perhaps more than they need, generally designing and making every main unit to his own ideas.

Attitude Toward Stock Components

There is no pronounced expansion of the components side of the industry. One or two quite small concerns who have yet to make a name for themselves have commenced to supplement Wrigley in supplying gearsets, axles and steering outfits. But they do not count for very much, and, speaking broadly, the car manufacturer makes every component himself.

Admittedly Dormans and Tylors have turned out a lot of engines during the past eighteen months, but Vulcan, Ruston Hornsby (Dorman) and Angus Sanderson (Tylor) are the chief users of their engines. Both do far more business in truck engines, making, between them, for W & G, A.E.C. and Hallford among others, who, usually, do not advertise the fact that they are fitting engines of other than their own make.

In fact, the frame of mind among concerns and individuals in the British automobile industry is that it is discreditable to use stock components. There is no discredit attaching to Humber, for example, in getting some engines made to their own design by Peter Brotherhood (the general engineering firm whose own tractor did so well at Lincoln); but if they made use of a stock engine they would feel they had reason to be ashamed—they would look upon it as implying that they were not qualified, had not enough brains and experience, to design and make their own.

So with clutches, gearsets and back axles. The general opinion is that no self-respecting manufacturer would do other than use these as designed and produced in his own

No wonder, then, that British cars are highly priced when the foregoing is considered alongside the comparativley small outputs. The writer could mention offhand a score of firms, whose names would convey nothing in the United States, who are turning out small and medium powered cars at the rate varying from only 100 to 500 per annum and who make every component. It is the same in all branches of the industry—private cars, trucks, motorcycles, marine outfits and tractors—all makes have their individual components, apart from accessories such as carbureters, magnetos, etc.

New High-Speed Cutting Tool Alloy

A DEMONSTRATION was recently made at Sheffield, England, of the cutting powers of a new alloy produced by the Cooper Research Co.'s laboratory, Cleveland, Ohio, and known as cooperite. The basis of the material is nickel, and there are added tungsten, silicon, molybdenum, aluminum and zirconium—the latter up to 15 per cent. These ingredients are melted in a crucible furnace, cast into tools, and ground, no heat treatment being required. The material has a fine silky fracture, and, it is claimed, is free from shrinkage and blow-holes. Tools made from it have been tried by the Sheffield Testing Company, with very interesting results. For the tests the tools used were ¾ in. square, depth of cut 3-16 in., traverse per revolution 1-16 in., cutting speed 123 ft. per minute, and the weight of material removed from the test bar 4.85 lb. per minute. One tool ran for 9 min. 6 sec., and another for 14 min. 39 sec., the report in the latter instance being that at that time the tool was "slightly worn, but still cutting," while a tool of high speed steel was said to have been "done up" after 2¾ min. The British rights have been secured by London interests and the alloy will shortly be marketed in England.

Cutting Costs in the Manufacture of Small Units

A detailed study of the parts to be manufactured often reveals opportunities for cutting cost before unknown. This article contains a description of special tools and methods used by a carbureter company in manufacturing the small units which go to make up its product.

By J. Edward Schipper

IN the manufacture of carbureters and other small units, there are many opportunities for cutting costs which are not apparent except when a very close and detailed study is made of the parts to be manufactured. For maximum efficiency, the operator must never wait for the machine. This principle is true from the standpoint of the manufacturer, as well as from that of the operator himself, who is thus afforded every opportunity to make the most out of his premium or piece-work arrangements.

Another consideration which comes up very frequently in the manufacture of small parts, is whether to use hexagonal or round stock. It is oftentimes possible to save money on the stock by using round in place of hexagonal, even where hexagon heads have to be milled on the piece. The time necessary for the "hexing" operation, however, must be taken into consideration.

In the plant of the Zenith Carburetor Co. there are two or three notable examples of marked advances in efficiency by the installation of machines which handle relatively small parts. Fig. 1 illustrates a machine for cutting hexagon heads on round stock. This machine saves the Zenith Carburetor Co. 12 cents per ft. on material alone. The hexagonal stock would weigh 2.89 lb., as compared with 2.54 for the round. The price difference is 2 cents per lb., even on the same sizes, but considering the smaller weight it is possible to use with the round material, the money saved on stock is 12 cents per ft.

Furthermore, with hexagonal stock it is necessary that the nut or hexagon be the largest part of the piece. There are times when this proves inconvenient, from an assembling and accessibility standpoint, as is the case on the Zenith carbureter, where the parts are close together. The pieces manufactured on this machine have a hexagon 5/8 in. across the flat and of 1/4 in. depth. The machine is a duplex type, cutting on one side while loading on the other, and turns out 20 of these per minute. It operates so quickly that the number turned out per minute is entirely dependent on the skill of the operator in loading and unloading; he cannot quite keep up with the machine.

Efficient Machine Work

As will be seen from Figs. 1 and 2, there are two independent drives, one for the cutter spindle and the other for the feed, and for rotating the work holding spindle. The cutter is 5 in. in diameter with fifty ordinary straight teeth. It is made of high speed steel and has turned out 150,000 pieces without being reground. The machine has a cam feed operated by a drive independent of the cutter drive. It is started by the operator pulling a lever, and the cam feed is so arranged that a quick motion of the swinging arm carries the work up to the feed; then the cam moving the swinging arm goes out of operation and allows the work to follow the contour of the master cam, which is identical with the shape to be cut on the piece. That is, the master cam may be hexagonal or square, or any other shape. This master cam rotates with the work when it is moved over by the swinging arm cam, and comes in contact with a hardened block on the machine which acts as the cam guide, the cam traveling according to its contour on this hardened block, thus moving the swinging arm to and fro.

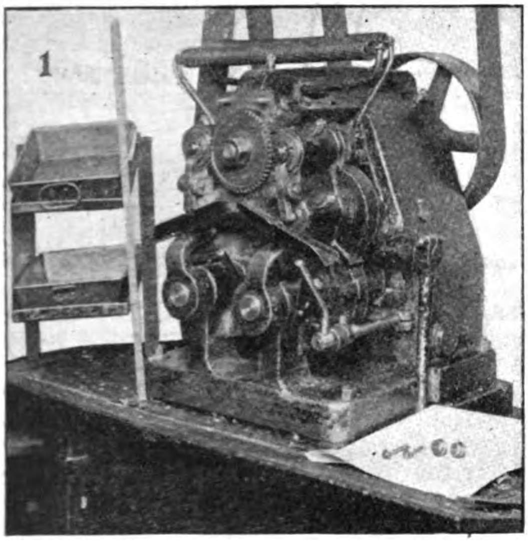
Table Operating Cam

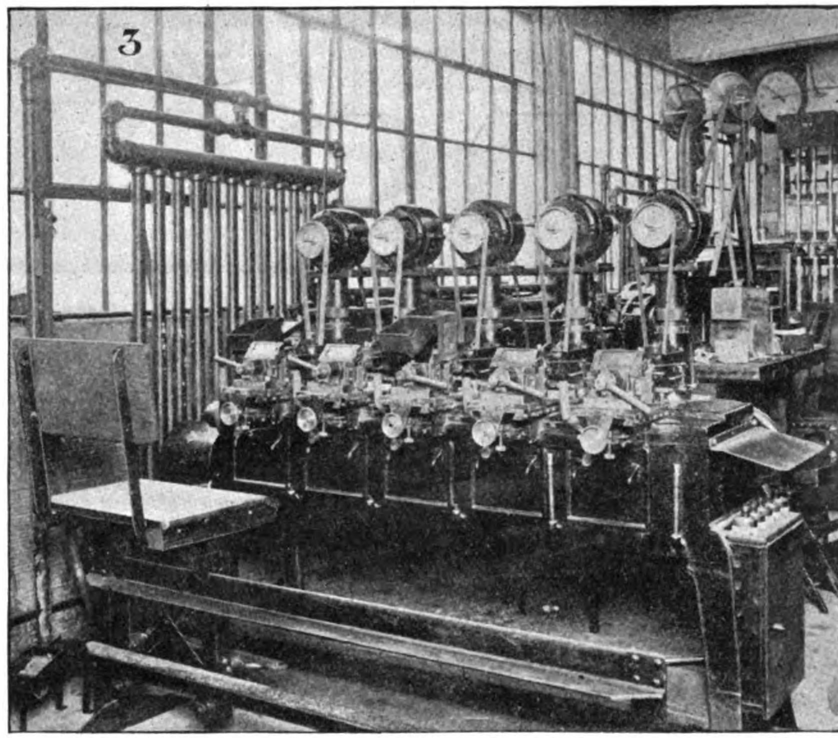
After the work has made two revolutions, the table carrying cam comes into operation again and moves the work away from the cutter so that the operator can remove it. The table has a quick motion away from the work, due to the shape of the table-operating cam. This is a one-revolution cam swinging the table quickly to the work, releasing it for the master cam to take up the action, then picking it up again after the cutter has done its work, and restoring it to its normal position. The table with its master cam is held against the hardened block by a spring, the action of which prevents bouncing and chattering. The spindle holding the master cam at one end and the piece at the other is geared 2 to 1 off the table camshaft.

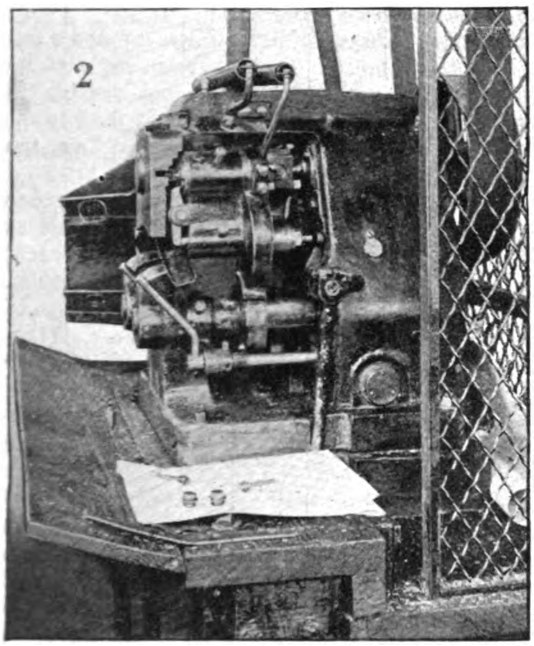
This machine, which has been patented by the Zenith Carburetor Co., has a cutting speed of 800 ft. per min. on brass and 100 ft. per min. on steel. It operates at high speed taking a very light chip, this having been found to give the best result with the brass composition used for carbureter parts.

Another machine used by the Zenith company for manufacturing small brass parts, is used for slotting the throttle shaft. This machine cuts a slot 1 1/4 in. in length by 1/8 in. wide in a 5/16-in. shaft. In order to give a layout which is sufficiently fast for the operator, a bank of machines is used with a chair placed on a track in front of the bank of five machines. The operator is thus able to slide rapidly up an down the row of machines and keep all of them in operation. A good operator can keep eight of these machines busy under normal conditions.

With this bank of five machines it is possible to slot four shafts per minute. The advantage of this machine over stock machines for the purpose is that the work is brought rapidly into position by the machine itself, instead of being screwed into position by a hand-operated, cross feed before the automatic speed of the machine comes into operation. By means of a cam the table is brought quickly up to the cutter and then the slow feed starts. When the cut is completed the table is backed rapidly away and the







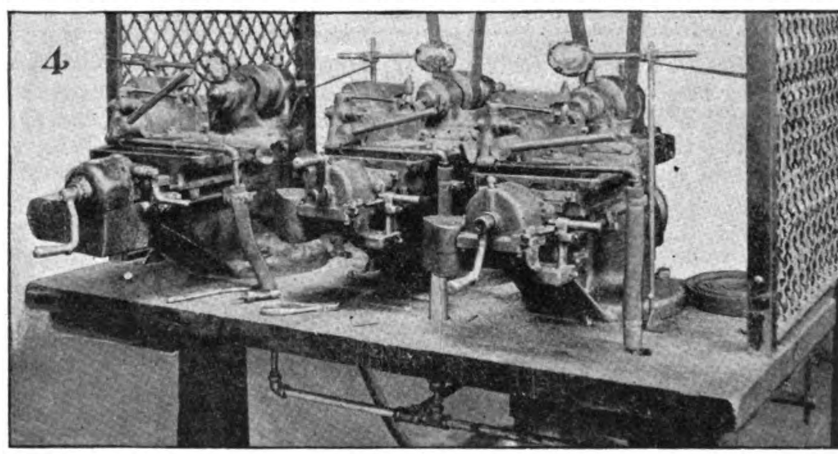


Fig. 1—Special machine for cutting hex or square heads. Machine is capable of turning out 20 pieces per minute, cutting on one side while loading on the other. Two sample pieces, one with a hex head and the other with a square head, are shown adjacent to the machine The guard plate in front of the cutter is removed. Fig. 2—Another view of the machine for cutting hex and square heads. Note the spring on top of the machine for keeping the swinging arm cam in contact with the hardened block on the machine, as described in the text. Fig. 3—Bank of five machines specially designed for cutting slots in Zenith carbureter shaft Fig. 4—Machines replaced by special machine for cutting slots in Zenith carbureter throttle shaft. These machines must be brought into position by hand rotation. On the improved machines the automatic arrangement quickly brings the table into position, after which the slow feed comes into control

mechanism stops, permitting removal of the finished piece and the insertion of a blank. It is then restarted by the operator. A very ingenious feature on this machine is a safety cap which comes down over the cutter, as the work is being backed away, so that while this is revolving continuously, there is no danger of cutting the operator's hand while placing the work in position.

The spindles are driven by independent electric motors at 10,000 r.p.m. The feed camshaft is driven by a single motor, which is located at the side of the machine and drives the one-revolution cam which brings the tables up to their work, gives the necessary slow feed for this operation and then, when the cut is complete, rapidly backs the work off and stops the machine until it is restarted by the operator.

The object aimed at in these machines and which is being pursued throughout the factory, is to have the machine do every bit of the work of which it is at all possible to relieve the operator. The stock machines replaced by the second machine described are shown in Fig. 4. The rotary hand feed necessary to bring the table up to the work before the automatic feed picks it up, is illustrated. This, of course, has the disadvantage of being slower, more irksome for the operator, far less foolproof and much more apt to cause breakage of tools. These are highly specialized machines, of course, and their specific features would not be adapted for other installations. They serve to relieve the operator of muscular and mental strain, for his own benefit and for that of the firm. He is not required to concentrate to the same degree, with the result that mistakes are less likely to occur. Furthermore, the work is done more rapidly and, consequently, production is greater than with the general type of stock tools.

The FORUM

The Proper Method of Measuring Starting Torque of Engines

Editor AUTOMOTIVE INDUSTRIES:

It is now common practice for automotive engineers to use the winter cranking torque of an engine as the determining factor in selecting a suitable starting motor, as it is well known that the winter conditions are the most severe to be met. In addition, the battery performance is much lower in winter than in summer, and this in turn lowers the performance of the motor. While engineers agree on the above, I find that there is a diversity of opinion as to the nature of cranking torque performance of an engine at low temperature and as to the proper method of measuring same.

It frequently happens, when an engine is very cold, that it is very hard to break the moving parts loose. This fact, along with tests where an oscillographic curve is taken of the starting motor current, will at first lead one to believe that the most severe condition is the break away, and that, consequently, the locked torque of the starting motor is the important characteristic to be considered.

It is my opinion that when the above break away condition exists, it is due to the presence of moisture in the crankcase, same having frozen at the low temperature, or in some cases where different kinds of metals are used in bearing caps, crankcase, etc., the bearings contract so as to actually seize the shaft.

Tests in which the writer has participated would indicate that at low temperature the cranking torque of an engine is proportional to the cranking speed, and the lower the temperature the greater will be the relative increase in torque with speed. Such being the case, it becomes apparent that it is not so much the locked torque as the speed-torque characteristic of the starting motor which is important, for if the motor will crank the engine at the required speed at say 10 deg. Fahr., then there is little chance that it will not meet the break away and summer cranking conditions. The summer cranking speed must, however, be sufficiently high to prevent what has been termed hunting, i.e., prevent the Bendix pinion flying in and out of mesh when going over the compression points.

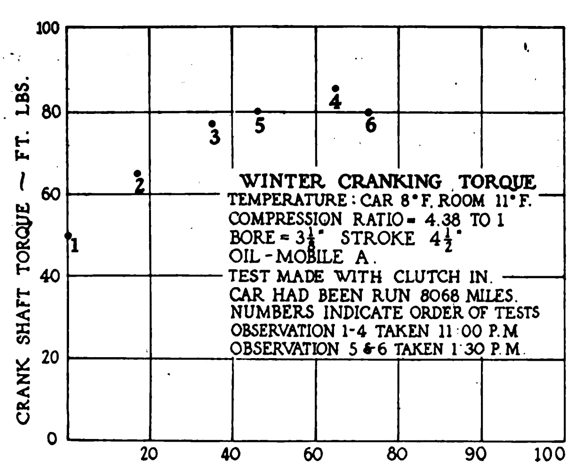
The proper way to measure starting torque is to gradually increase the applied torque until the crank starts to move. The applied torque at this point is equal to the break away torque. The applied torque should then be increased and after the speed becomes constant, the torque and speed observed. Make observation at several different speeds, and from the data obtained a curve may be plotted.

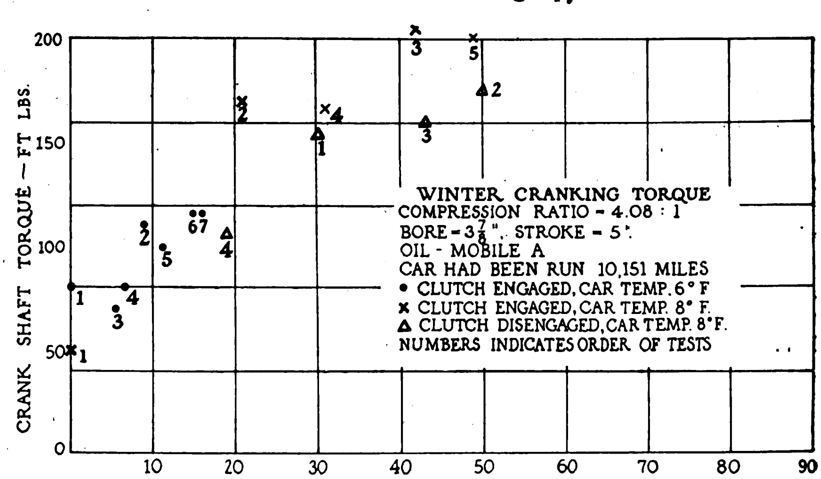
The two enclosed curves represent the winter cranking torque performance of a six-cylinder 207 cu. in. and a six-cylinder 354 cu. in. engine. The tests were made at approximately 10 deg. Fahr. in a large ice box constructed for experimental purposes. Mobile A oil was used in the engines, both of which had been run several thousand miles prior to these tests.

The cooling water was drained from the engines, and they were then run into the ice box, which had been cooled to near zero temperature. The cars were left in over night and the temperature was regulated so that in the morning we had approximately 10 deg. Fahr. The temperature of the battery electrolyte observed as that of the car. Thermometers were also placed in a bottle of oil in the same room.

To measure the torque, we had a calibrated starting motor with back gearing, the back geared shaft connecting to the front end of the crankshaft. The starting motor current was supplied by two six-volt batteries connected so we could throw from two to six cells in series, and in addition we had a rheostat and ammeter shunt in the line so that the current could be regulated and its value observed.

We would first gradually raise the current until the engine shaft would just barely turn over, and the observed current was taken for calculating the break away torque. The line resistance was then decreased and the switch closed. When the speed became constant the current was observed, and so on, until we had the current draw for several different speeds. From the calibration curves we then interpolated current draw to torque for each speed and plotted curves such as those herewith. Later on in the winter we checked the cranking speed of the small car





Cranking torque of automobile engines when cold

after leaving it outdoors over night, and found that the results checked closely with those obtained in the ice box.

All of these tests proved to us that within the range of winter cranking speeds the running torque was greater than the break away torque.

As to the general law that the friction of rest is greater than the friction of motion, I believe that conditions here do not warrant its application. This law I believe applies to friction between solids, whereas we are concerned with the shearing friction of congealed oil. I believe, if you will imagine yourself wading in a tank of congealed oil or similar substance you will have a fairly close idea of the condition in a cold engine, for it seems easy to conceive of the required effort increasing rapidly the faster you try to move.

In making tests of winter starting torque the inertia effect should be eliminated and also any other external influences which might affect the results.

The oscillographic curve method of measuring the starting torque I consider misleading, especially when full battery voltage is applied and the observed starting motor current recorded as the engine comes up to speed. In the first place, this method does not eliminate the inertia effect, which is a big factor, and in the second place the natural starting characteristics of the motor, even without load, would result in a high starting current which diminishes as the speed increases. Take the well-known equation of an electric motor:

$$E = IR + E_c,$$

where E is the applied voltage; E_c, the counter E.M.F. of the motor (which is a function of the speed) and IR the resistance drop in the motor. In starting, E_c is zero; therefore

$$E = IR \text{ and } I = \frac{R}{E}$$

Starting motors have a resistance of 0.006 to 0.008 ohm. Therefore, the current I at starting must be large and the falling off as the speed increases is an electrical characteristic entirely independent of the torque characteristic of the load. Of course, the exact shape of the oscillographic curve would be affected by the load. However, as the speed increases, E_c increases and IR must drop. R being constant, the drop is all in the current.

The principles advanced in this article are based on the assumption that the liquids in the crankcase or cooling system are not frozen solid, which should be the case at 10 deg. if the car is properly taken care of. P. J. KENT.

The Over-Geared Fourth

Editor AUTOMOTIVE INDUSTRIES:

In your editorial on Page 1035 in the Nov. 18 issue on the Question of Over-geared Fourth Speeds, you make some statements to which we would like to take exception.

You intimate that the primary object in using an over-geared fourth speed is to get maximum car speed. Our object in the design and use of a four speed transmission with an over-geared fourth was not primarily to obtain high car speeds, but was to obtain better economy at touring speeds without sacrificing good low speed performance in traffic on direct drive, and also to use a lower engine speed for touring.

We agree with your statement that "from a fuel economy standpoint it is always advantageous to use the highest gear possible, provided it does not pull the engine down to a speed where it runs unsteady and begins to knock." Fuel tests have shown that the gasoline consumption per b.hp. hour increases very rapidly from the one-half load throttle position to the nearly closed throttle position for any given speed. Therefore, if an engine were so geared to the rear wheels that it required nearly half of full engine power at a given speed to propel the car, very good economy would be obtained. It is easier to do this at the higher car speeds generally used for touring, say from 30 to 45 m.p.h., than at speeds used for city driving, since there is less need for quick acceleration at the higher speeds and therefore the engine can be used nearer to its maximum capacity.

In selecting the total reduction between engine and rear wheels, two conditions should be considered, city driving and country touring. One ratio cannot fill these two conditions as well as two when both economy and performance are considered.

A great deal can be said on the subject of gear ratio and its relation to car weight, performance and economy, and it would take several pages to go into this fully. All of these factors must be studied in relation to each other and with the engine characteristics, in order to make the best selection of gear ratio to meet the desired conditions. The fuel consumption curves of engines generally show that the best economy at both ½ and ¼ full load lies within a small range of the engine r.p.m. If the engine is so geared that this range is used for city driving on direct drive, good economy can be obtained, and then by gearing up for touring so as to use approximately the same range of engine speeds for the higher car speeds, good economy can also be obtained for touring. This selection is always a matter of compromise and depends on which feature is preferable, rapid acceleration and hill climbing ability or economy.

For the one who does both city driving and touring, economy is important under each of these conditions and can best be obtained by using a different gear ratio for each condition. The most economical ratio for touring would be altogether too high for city driving and since it is preferable to do city driving on direct, the ratio for touring would be an overgear. The increased noise is not so objectionable at the higher speeds. Therefore, the over-geared fourth is not a feature of luxury, but one of economy, on the car which is used for both city and country driving. HERBERT C. SNOW, *Engineer*,
The Winton Company.

Spare Parts on Export Cars

Editor AUTOMOTIVE INDUSTRIES:

I was much interested in Mr. Jennings's article of the 6th re selling spare parts with export cars.

Naturally, foreign business men do not like to be required to do anything, but, one would suppose that if they were really reliable, they would wish to take up the service end of the business. In any case, I cannot imagine any company with a real desire to build up a lasting export business shipping cars without spare parts any more than they would omit the electrical equipment.

It seems to me that it would be a good plan to include a certain number of the most essential spare parts as part of the equipment with the initial shipment; the cost to be included in the price of the cars. The dealer would not then feel that he had been compelled to do anything, and, after realizing the utility of the spares sent, would in all probability hasten to order a complete stock.

This plan need only be followed where the dealer omits to pay attention to this important matter.

Cobble Hill, B. C., Canada. MILWARD V. HARRIS.

THE British Board of Trade has issued a license under Section 20 of the Companies (Consolidation) Act of 1908 to the British Motor Cycle and Cycle Car Research Association, which has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research.

The Importance of the Labor Problem Has Not Diminished

The present industrial situation affords manufacturers an exceptional opportunity to put their house in order. When working forces are built up again, effective methods will insure an efficient working force. This article reviews three new books which discuss this phase of production.

THE labor situation at present involves more potent though less obvious dangers than it did six months ago. There are more reasons for labor to be discontented and a more favorable opportunity for the spread of unsound radical doctrines. The fact that labor is not in a position to give voice to that discontent as loudly as at this time last year has given to some the false impression that the whole problem has been solved. As a matter of fact, its growth and complexity has really become greater with the unemployment and social questionings which inevitably accompany it.

The advantageous position which employers occupy in relation to labor, however, provides them with an exceptionally good opportunity to study thoroughly those problems relating to the human element and to apply them effectively.

If employers during the next six months can give a thoroughly square deal to their employees, even though not forced to do so by economic pressure, they may confidently expect better co-operation from labor when business conditions return to normal and labor is again in greater demand. If the favorable opportunity is used for the application of repressive measures, however, a continuation of the fight by labor when it gets in the saddle may be just as confidently expected.

Because the present time is especially favorable to the study and development of effective personnel methods, particular interest attaches to books which bring together the standards of practice in such work insofar as such standards have been developed. Much theory has been written on this subject, some of it well worth reading, but descriptions of practical methods and standards have to a large extent been confined to short articles and specific instances.

Three books have recently been published by the Ronald Press Co. which embody much practical information of value to the man actually engaged in personnel work. The one entitled "Employment Methods," by Nathan W. Shefferman, is worthy of note as being almost the first book on this subject to offer exact and detailed practical help to the employment manager. In contrast to "Personnel Administration," by Tead and Metcalf, reviewed recently in AUTOMOTIVE INDUSTRIES, Shefferman's volume will appeal more to the man actually involved in the operation of employment work than to the theoretical student of industrial affairs. It was said of the Tead and Metcalf book, "If this excellent discussion of principles could be supplemented by a more practical book concerning the actual methods and forms to be used in installing and operating personnel work, the literature on this subject would be much more complete than it now is. The latter phase has not yet been satisfactorily treated. "Employment Methods" is best described briefly by the statement that it does treat all of the practical phases of employment work in a detailed manner.

A part of this book will be elementary for the man familiar with employment work, but its inclusion renders the volume a complete guide for the novice desiring aid in establishing employment work for the first time.

A carefully devised set of forms for use in connection with every phase of employment work is presented and thoroughly explained in the two chapters, "Employment Forms." Unnecessary red tape has been cut out and only essential forms have been included. Sufficient routine is included, however, to enable the employment manager to learn from his records all the details necessary to an intelligent administration of his department.

A few of the forms used in connection with job analysis will appeal to some as being theoretically excellent but somewhat complicated for practical use. The text matter relating to job analysis, however, is very good.

A helpful chapter is that in identification systems. Several complete systems are described and illustrated, each adapted to a different type and size of factory.

A chapter is devoted to a discussion of proper advertising methods as a means for securing workers. It is worth the attention of every employment manager or other executive who ever has occasion to insert want ads in the newspapers or trade journals. Many want ads fail to bring the best returns because they are not prepared in the right way; the wrong key-word is used, too many words are jammed into a small space, the text is not clear, etc. A detailed analysis and description of what constitutes effective "help wanted advertising," together with the best methods of utilizing it, are contained in this section.

Part IV of this volume is devoted to employment methods for the office, and comprises a detailed examination of the systems used by certain concerns which have developed their office employment departments to a high degree.

Being as it is a book of practical methods, "Employment Methods" does not lend itself to review by extensive quotations. It nevertheless very definitely fills a long felt want.

Another book which will be of value to the personnel executive interested in giving particular attention to industrial relationships at this time is "Labor Maintenance," by Daniel Bloomfield. This book does to a large extent for employees' service work what the Shefferman book does for employment methods. Since the matter of employees' service is in itself less practical, however, the book which describes it must necessarily fall below the other volume in this respect. "Labor Maintenance" is of interest chiefly as being a complete summary of all the things which have

been done along this line by various well-known firms throughout the country.

The author recognizes that definite standards for such work are altogether lacking, and he has made little attempt to set up such standards, except in the case of a few fundamentals.

This book will give to the personnel manager a large number of ideas as to activities that might be conducted along this line, and it will give him as well, in many instances, detailed instructions for carrying out these activities.

> **The chapters on Americanization are exceptionally sane, as for that matter is the treatment of that subject in Shefferman's book. "The best and most lasting achievements in Americanization work," Bloomfield says, "have resulted from indirect rather than direct influences. If the spirit and surroundings of the plant definitely suggest Americanism, a large part of the work has been accomplished. . . . Every executive, every foreman and every employee must be impressed with the matter of maintaining American standards with regard to the immediate surroundings of the shop, mine or mill."**

Some of the author's conclusions in regard to housing and community effort on the part of the employer are open to dispute, but contain material well worth discussion. Folk festival and pageants of nations, for instance, may be very effective if rightly conducted, but they may also cause the expenditure of a great deal of money without any adequate return accruing to the organization. This is certainly true in one of the cases cited by the author.

"Labor Maintenance" constitutes the best summary of employee's service efforts thus far published and lays an excellent groundwork for the establishment of more definite standards of practice.

Although it touches very directly upon the labor situation, "Training Industrial Workers," by Roy Willmarth Kelly, makes a somewhat different appeal than do the other two volumes included in this review. While Dr. Kelly's book contains some practical material of use in establishing training work, its chief merit lies in the social background and the social potentialities for industrial training which the author develops in a most interesting and thorough manner.

In his preface appears an excellent summary of the lines along which progress should move in regard to industrial training: "It is essential that private manufacturing establishments should avail themselves of every possible opportunity to secure the assistance of public and private educational institutions. It is essential on the other hand that educators should constantly modify their theories and methods in the light of the needs of progressive industrial concerns."

The development and growth of apprenticeship and modern industrial training is discussed, together with the function and possibilities of the various public and private agencies interested in the training of industrial workers. Executive and foreman training is also treated briefly, as is vocational guidance and the part which the manufacturer may play in it.

The treatment of the educational value of democratic participation in management is an excellent contribution to contemporary thought on this subject. A few pertinent ideas expressed by Dr. Kelly are embodied in the following quotations:

"Because of the general tendencies of the time in state and national government, it is only natural that co-operative management plans should multiply among industrial establishments. The demand for a modification of the old democratic control of the shop was by no means created by the war.

> **"Every thoughtful worker is able to detect evidences of inefficiency on the part of his superiors, and because he knows little or nothing of the real difficulties involved in executive control, he is . . . frequently bitter in his denunciation of the policies of the firm. . . . One of the chief weaknesses of many large concerns is the inability or unwillingness of the leaders to tap the immense reservoir of knowledge and ability possessed by the rank and file of the organization."**

While these three books were written separately, one fact impresses the reader after studying the three. Each author emphasizes, in his own way, the necessity for a thorough analysis of all the factors which go to make up the problem of human relationships before a successful application of any methods can be expected. It is this study, analysis, and experiment which has been emphasized constantly by Mr. Tipper as a primary requisite to the successful solution of the problem of our industrial relations difficulties.

Formulating Formulæ

Do you remember when you studied physics in high school; when facts came on you thick and fast, and when it sometimes seemed impossible to logically reason out the various steps by which the different formulæ were obtained? Did you ever give up in despair, just before examination time, and simply memorize all the formulæ you could lay your hands on? Then go into the examination and solve the problems presented by trying first one formula and then another in the hope that you might by chance find the one that would fit?

Later experience has taught, of course, that such methods can never lead to an intelligent or valuable knowledge of the subject. But somehow or other the formula idea remains with many people long after their high school days. A formula is so convenient. You just substitute certain values, multiply or divide, and there you have it. But in most problems of life values are quite variable and formulæ frequently incorrect in their solutions.

Probably no phase of management has been hindered and misdirected by the formula evil more than that of human relationships in industry. It is so much easier to try one ready made formula after another, than to carefully study and analyze the complicated factors involved in the problem.

Playing upon this too common weakness, many clever men are making a living writing and selling formulæ. A new one appears every day. Read this one that came to a prominent manufacturer recently:

"Enclosed is a folder entitled 'The Power of Knowledge,' that *briefly* points the way for you to obtain a *complete personal mastery* over *every* labor problem in your organization." The italics are the editor's.

Presto! The labor problem is solved. "Ain't it a grand and glo-o-orious feeling?"

Analyzing Present Increase in Individual Labor Efficiency

The visible usefulness of the work being done by any man has a direct bearing upon his productive capacity. Wages alone are not sufficient to urge the fullest use of abilities. If necessity obliges, you will shovel sand all day, but your chief desire will be to escape that kind of work.

By Harry Tipper

A GOOD deal has been said lately regarding the increasing efficiency of the worker, now that the shortage of labor has past and he is beginning to be troubled with the old economic fear of being out of work. This fact has been referred to as an evidence that the labor trouble has past, and is a cause of much satisfaction in many quarters.

As far as it alleviates the difficult situation in which we find ourselves in respect of labor, it is a very satisfactory change, but it should really induce us to analyze the causes of these fluctuations in the efficiency, and find out why it is that the incentive to efficiency is dependent upon the production situation from the standpoint of employment.

We know from experience with many classes of employees, that unless there is some other incentive than the wage, we have not induced the employee to put forward his maximum capacity and we cannot hope to secure a high proportion of that capacity in every-day work unless the wage incentive is supplemented by other points of value in this respect. While the increase in the efficiency of labor in the last few months is a considerable improvement over the previous situation, therefore, it is an illustration of the weakness of our present methods of industrial organization; particularly as it points out the lack of control we have over the production effort of the worker, and the interest which he will have in his work.

Two or three years ago when these articles were started, the statement was made that there is no incentive in human beings merely to work. There is an incentive to useful accomplishment, and it is this incentive which induces the man to labor.

In the days when prisoners in a jail were not given any work, one of the wardens in a Middle Western State conceived the idea that it was demoralizing to have all these prisoners spending their time in brooding and in getting up plots. He felt that there ought to be some occupation for them. He had no means of putting them to a regular occupation, but there was a pile of stones in one end of the prison yard and he set the prisoners to work moving that pile to the other end of the yard and then taking it back again. In the course of a week two men had gone insane, several of the other men were very fractious, and a goodly number were sick.

The diagnosis of the medical men who were called in was mental disturbance due to the irritation of the useless work. It was not, of course, stated in this everyday language, but that was the gist of their diagnosis.

The absolute uselessness of this work was visible to the prisoners. They could not escape it and instead of being an advantage, it became a torture.

No human being will stay on useless work, and the incentive to work is in proportion to the visible usefulness of the work which they are doing.

If I am obliged by economic conditions in my individual case to shovel sand all day, I can do it, and I will make shift to get through with it. But the principal desire on my part will be to escape from that kind of work at the earliest opportunity, and I will probably reach my maximum capacity only as the fear of starvation obliges me to work harder.

The work which the individual worker has to do in industry varies very materially in the degree of visible usefulness. A large part of it is monotonous and repetitive in its mechanical requirements and very narrow in mental requirements. It is not particularly interesting in itself, because there is no visible growth of usefulness while the work is in the hands of the operator. For that reason the principal desire is to escape from the work, to work as few hours as possible and to do no more work than is necessary to maintain their position.

This is not true of all the work in industry by any means, particularly in the metal trades field, there are many jobs where the individual skill of the worker, his judgment, and so forth, enter into the work to such a degree that there is a visible growth in the usefulness and the creative impulse is satisfied by the conditions themselves.

Where observations have been taken in such classes of work, it is to be noted that there is a steady production effort and the relation between the amount of effort and the necessity for hanging on to the job is not so definite. There has been a definite improvement in this respect, in those plants where a concerted effort has been made not only to provide a fair treatment for the workers, but to educate them as to the place of their work in the useful production completed by the plan.

A friend of mine some years ago was general manager of a plant, manufacturing building supplies, particularly copper work and all kinds of special moldings. The plant was being run on the old basis, that as long as you paid the worker a proper wage no other attention was necessary. There was a good deal of dissatisfaction from time to time and a lack of any real esprit-de-corps.

This friend of mine was going over some photographs of the work as it had been installed in one of the important buildings in the State. He thought the men in

the factory might be interested. As he studied the matter his thoughts grew until he finally constructed a bulletin board, in itself an example of the finest work in the plant and the most careful artistic treatment. On this board he showed photographs of the various installations of the work with the names of the men who had been concerned in its manufacture. The pictures created so much interest that the plan was followed out regularly and it was finally extended so that on each job a blue print or a drawing of the completed structure for which the work was required, was put up in each department.

The change in the situation inside of six months was quite remarkable. The usefulness and value of the work which they were doing was impressed upon the workers by this means. They saw the reason for the accuracy which was demanded and the care which they were expected to take in their operations. A sort of renewed spirit of craftsmanship got into the plant and the effect upon the character and value of the output was distinctly noticeable.

Furthermore, difficulties were more easily overcome, and the men proved sufficiently interested in their work so that they were willing to double their efforts in an emergency.

Showing the worker the part which he plays in developing the useful product and the relation which his work bears to the value and the service of that product, is a method of improving industrial relations which has great possibilities.

If the whole value of the potential capacity of the man is to be secured and kept working on his job, the intelligence and sentiment must be captured just as much as the economic interest must be satisfied.

A great deal can be done in capturing the intelligence and the sentiment by this means of education upon the work itself. It is not an easy matter to develop this so that it will be suggestive, agreeable and of value to the organization. It requires a keen knowledge of the workers themselves, a careful understanding of the factory methods and production, and an ability to present the information in such a way that it will not be recognized as education, but simply as general information about their work.

Incentive to useful accomplishment leads to the development of the best capacity of the man, where the usefulness of the accomplishment becomes visible to him. It will be worth considerable time and effort and money to make the usefulness of each industrial job visible to the worker, so that he is provided with a pride in his work, and what it means, with an understanding of the reasons for its accuracy and quality and with a knowledge of the value of speed in its completion.

Tractors in Louisiana

THERE are to-day 5,622 tractors in operation on Louisiana farms. This State, it is said, leads the South in power farming, and no other State of the South, save only Texas. approaching Louisiana in the number of tractors in use. The Louisiana allotment of one popular-priced tractor for the coming year is 4,000, while another manufacturer has placed the allotment of his machines to the same territory at 1,500, so that there should be, before next November, at least 12,000 tractors at work in the Pelican State. In all probability this number will be exceeded by at least 1,000, but the 12,000 is a safe estimate. This means one tractor for every four and one-half farms in the State, there being 54,000 farms in Louisiana.

The rice farmers are the most advanced of all the tractor users. Up to some seven years ago, only a few farmers in Louisiana—and those mainly the large plantation owners—had tractors. The majority of these tractors were in the rice "pocket" as this section of the State is called, while there were few in the sugar "bowl," and virtually none in the cotton "belt."

To-day every successful rice-producer has at least one tractor; many have two, and some are operating three or more. For them, the tractor cultivates the ground, puts embankments around the field to hold in the water, pumps off the water at the right time, cuts the rice when it is ripe, threshes it, sacks it, and, not infrequently, hauls it to market. The only thing the tractor has not been able to do in the rice industry is to stick the plants in the mud. This has to be done by hand.

The larger rice-planters find it advisable to run both large and small tractors, the former for deep-land breaking and operation of threshing machines, and the latter to harrow, to pull the cutters and binders, and tie the grain in bundles for the threshers. Farm power for preparing and cultivating the land and for harvesting and threshing the grain is second only to irrigation in the rice industry, and often is the limiting factor in rice production.

The sugar planters use the tractor not to prepare the land, but to cultivate the growing crop, yet it was some time before the tractor was developed to the point where it could care for the growing cane of various ages as well as cultivate and seed the ground and harvest the full-grown crop. By working with two types of tractor, one for breaking the ground and seeding and harvesting, and the other, a higher machine, for straddling the rows and cultivating the growing cane, the sugar men gradually came into general use of the tractor.

In the sugar district, the most commonly used tractors are the Cletrac, Moline, Universal, Fordson, Rumely and E-B. The rice men are partial to the Advance, Rumely, Case, Avery, Waterloo Boy, E-B, Twin City, I. H. C., Samson, Fordson, Huber, Russell and Wallace.

The application of the tractor to the cotton industry never has gained the momentum it has in the sugar and rice sections, largely because the cotton planters, working on higher, dryer and more easily cultivable ground, have not had occasion to seek machinery to do their work to the extent the rice and sugar men have had to seek it. Far-sighted cotton planters, however, are devoting more and more attention to the tractor, and one of the greatest and most fertile fields for tractor sales lies in the "cotton belt" of Louisiana and Mississippi.

A COMMITTEE of the American Society of Mechanical Engineers recently collected a list of all the organizations in this country which are giving active attention to the problem of labor education. This list indicates that great interest is being taken in this question. Among the prominent agencies applying themselves to this work are: National Metal Trades Association, National Industrial Conference Board, National Association of Corporation Training, National Association of Manufacturers, National Society for Vocational Education, Federal Board for Vocational Education, American Academy of Political and Social Science, American Association for Advancement of Agricultural Teaching, American Technical Association of Pulp and Paper Industries, and several U. S. government departments.

Wood Conservation—a Necessity

FEW persons who have not given the matter some study appreciate the extent and importance of the wood-using industries or the necessity of conservation in the raw and finished material upon which they are dependent. The value of the products of the primary and secondary wood-using industries is said to aggregate **over ten billion dollars annually, and these industries employ more men than any other single industry in this country. Under these circumstances it is of course a necessity that conservation of forest products be practiced and encouraged by every possible means. A great work in this direction has been done by the Forest Products Laboratory** which is a branch of the Forest Service of the U. S. Department of Agriculture. It is conservatively estimated that the commercial application of research work carried on by the laboratory is already saving the country **$30,000,000 annually.**

The automotive industry is a large user of wood and has profited in no small measure as a result of the work of the laboratory. It could profit to a much greater extent if the value of the work done was more widely appreciated. Information concerning economy and more effective use of lumber (with consequent safety in shipments), economical operation of kilns, preservation and finishing of wood, and much other information of great value along similar lines has resulted from the activities of the laboratory and is being distributed by it to the great good of all users of wood and articles in the construction or packing of which wood or its products are employed.

The Forest Products Laboratory is largely dependent upon Congressional appropriations for its support, and is seeking an appropriation of $400,000 for the coming year. **It should have at least this amount and members of Congress should be made to appreciate the value of the work done and the need of further research,** both from the standpoint of the industries directly benefited and the public which is certain to benefit in a still larger degree. **We urge that our readers look into the matter for their own good and then see that their Congressional representatives are duly informed of their views.** Particulars can be had from the laboratory itself as well as from the Association of Wood Using Industries, Monadnock Bldg., Chicago.

The Engineer as a Citizen

IN the past two or three years much has been written about the desirability of the engineer taking greater interest in civic matters and some engineering organizations have discussed the matter in open meeting without the response that we feel the subject merits. Although city, State and Federal Governments have much to do with applied engineering and government itself can and should be in large measure reduced to a true engineering basis, but few engineers have become prominent in public life and the type of engineer attracted by civic activities has not always been of the best. There are conspicuous exceptions to the rule which simply proves that the engineer who bestirs himself and applies his training in a logical way can with credit take his place in civil affairs, as well as men trained in other professions. Herbert Hoover is one who has done this, and another is James Hartness, Governor-elect of Vermont, an S. A. E. member and a manufacturer whose product is widely used in the automotive industry. Mr. Hartness is a past president of the American Society of Mechanical Engineers, and has recently served as a member of the National Screw Thread Commission on which the S. A. E. and A. S. M. E. are represented.

There is no reason why other engineers should not serve the community in public office, but those who do so will be few if engineers in general do not take a more active interest in civic affairs. Is it not true that the average engineer is so much bound up in his own—frequently very narrow—specialty that he loses perspective and fails to function as a good citizen should?

Suppose the 5000 members of the S. A. E. joined with the many thousands of engineers of other societies and made it a point to take an active interest

in civic matters. The effect of such joint activity would be nation-wide, and the engineer would soon take the place he deserves in the estimation of the public.

During the war the S. A. E. made a splendid name for itself through the whole-hearted co-operation extended to Government engineering activities. Work of similar nature is still being carried on, but neither the S. A. E. nor other engineering societies are taking the active interest in broader governmental matters which the needs of the hour or the importance of the engineering profession demand. Individual effort is commendable, but united effort alone will suffice to give the engineer the standing before the community which will be accorded if he will assert himself and insist upon the systematic application of engineering fundamentals in the conduct of Government affairs.

Fitting Traction Devices to Cast Disk Wheels

DURING the winter, when the road surface is covered with snow and slush, solid tired vehicles require anti-slipping devices applied to their wheels to enable them to get sufficient traction. These traction devices are different from the usual non-skid chains used on pneumatic tired passenger cars in wet weather. Usually they consist of a few lengths of heavy chain which are placed around the tire and wheel rim, and equally spaced around the circumference. In order to prevent the traction chain from slipping on the wheel, its ends must be securely fastened to the inside of the tire felloe or to the spokes. A great deal of difficulty is encountered in this connection owing to variations in design of the wheels. With spoked wheels the problem admits of a ready solution, as fastening hooks can be clamped around the outer ends of the spokes. Lately, however, steel disk wheels have come into extensive use, and in these no provision seems to be made for fastening the non-skid chains. Chains are absolutely essential if the truck is to be kept in service all the year round in this latitude, and the wheel manufacturers certainly could save users a great deal of trouble if they fitted chain attachment hooks to the wheel webs, or at least drilled holes through the wheel webs (according to some standardized plan) for fastening the hooks.

The way to widen the field for the motor truck is to make its use more convenient and less expensive to the owner, and the provision of non-skid hooks on cast disk wheels, while seemingly a minor matter, is a step in that direction.

Is a False Pretense Worth While?

NO man is perfect, of course. Naturally, it follows that human plans are unlikely to be perfect, but that is no excuse for misstatements or pretense even in publicity ventures.

These thoughts are prompted by two form letters which reached this publication a few days ago. Both contained the same hand-written corrections, evidently intended to fool the reader into believing the letter was not duplicated. In each letter the bidder for publicity said, "I made the selection of papers, chiefly the business papers I read myself."

But one of the two letters was addressed to a paper that has been out of existence two years or more! That spoiled the effect of the carefully laid plan. The pretense wasn't worth while, in fact it reacted against the person it was intended to benefit. This is true of pretense, whether practiced in form letter writing or elsewhere. It applies with special force to advertising, and that form of free advertising known as publicity is no exception to the rule.

Transmission Efficiencies

IN a paper recently presented to the American Society of Mechanical Engineers some results of transmission tests are given which are hard to understand. For instance, it is shown that the direct drive of a four-speed transmission is less efficient than any of the lower gears, and this is ascribed to higher gear speed and consequent increased oil churning when driving on direct.

Now, with constant engine or motor speed, as substantially maintained in these tests, and with a transmission of the conventional design in which the constant mesh set of gears is located at the driven end, all the gears on the secondary shaft run at the same speed whether the truck is being driven on "direct" or on any of the lower gears. Also, it is these gears which should have the greatest effect on the power losses due to oil churning, as they usually run submerged in oil, whereas the gears on the primary shaft are above the oil level. About the only explanation for the unusual results obtained that occurs to us is that the transmission was of a type—sometimes used in the earlier years—in which the constant mesh gears are located at the rear end. But if such an unusual type of gear was used we should think it would have been pointed out in the paper. This gear was given up for the very reason that when on direct drive—that is, most of the time, the secondary shaft with its gears is running at about twice engine speed, whereas in the usual type of transmission it runs at only about one-half engine speed under these conditions. That the direct drive is less efficient than the lower gears is not only contrary to the general belief, but contrary to most previous experimental evidence.

ON advertising page No. 142 there is employed a very different sort of copy from that which usually appears in AUTOMOTIVE INDUSTRIES. It is an appeal for all Americans to assist in the rehabilitation of Europe by saving 3,000,000 children from starvation. This advertisement is donated by AUTOMOTIVE INDUSTRIES to this cause. You will find in the last paragraph directions for sending the money and the names listed are your guarantee that the money will be well used.

Automobile Sales at Retail Spotty

Dependent Chiefly on Local Business

Trade Improving in Half of Chief Distribution Centers —Poor in Farm Districts

NEW YORK, Jan. 3.—Retail automobile sales conditions in the leading distribution centers of the country are distinctly spotty. They are dependent upon the local industrial conditions. Where the general trend of trade is upward, sales are improving, but in sections where the slump has not reached bottom the automobile business is at a standstill. In general it can be said that the cities which were the first to feel the full effects of depression and have reached an adjustment, are the first to show signs of recovery. This process probably will continue until normal conditions are restored again throughout the country.

Automobile sales are increasing slowly in most of the great industrial centers, but there has been little actual sign of improvement in the cities which are the trade centers of the agricultural districts. It is logical to assume that the farmer will be a poor prospect until the purchasing power of the dollar comes up to meet the values of the goods the farmer has to sell. The best sales prospects are to be found in cities with diversified manufactures. One industry cities, such as Akron, where depression has hit them at all, have suffered most.

Taken as a whole, the Southwest and the South seem to offer the poorest trade fields at present, while the outlook is most hopeful in the larger cities of the East and Middle West. Dealers in the oil fields of Texas are enjoying the best business in years and sales are normal in Southern California.

New England Business Better

New England, with its thousands of textile mills and shoe factories, was the first to bear the brunt of depression, and it is significant that business is better in Boston. Other industrial centers which show improvement include Buffalo, Cleveland, Detroit and Milwaukee. The effect of the great shrinkage in the value of agricultural products is evidenced by slow sales in Minneapolis, Des Moines, New Orleans and Atlanta.

The "spottiness" of conditions is best shown by the fact that while dealers in Dallas, Texas, territory are thriving as never before, those in Austin, Texas, report very little business. While trade is normal in southern California, it is not so good in the San Francisco territory and it is at a standstill in Oregon.

These facts are disclosed by painstaking investigations by correspondents of

SALES CONDITIONS AT A GLANCE

Here is a birdseye view of retail automobile sales conditions in the principal distribution centers of the United States:

SALES BEST IN YEARS

Dallas, Texas

SALES NORMAL

Los Angeles

SALES IMPROVING

Boston, Buffalo, Cincinnati, Cleveland, Detroit, Denver, Philadelphia, Kansas City and Milwaukee.

SALES AT STANDSTILL

Atlanta, Austin, Tex., Chicago, Des Moines, Indianapolis, Minneapolis, New Orleans, New York and Portland, Ore.

AUTOMOTIVE INDUSTRIES in twenty cities. It is significant that while there has been little increase in actual sales in nearly half the cities covered, the feeling of dealers is much more hopeful than it has been for months. They believe the turn of the tide is near and that the new year will bring a slow but steady improvement, with conditions approaching normal at the close of the first quarter. Their expectations are based upon a marked increase in the size of live prospect lists. If they can sell cars to even half the persons who have announced that they propose to buy in the spring, they will clean out their stocks in a very short time.

Surplus Reports Conflict

There are many conflicting reports regarding the surplus of cars held by manufacturers and dealers. So far as can be learned, however, the stocks on hand in most cases are sufficient to supply the normal trade for not more than two months. Dealers believe that unless the factories are in position to get into production rapidly, there will be a shortage of cars by April. This belief is largely speculative, but it is very generally held and is shared in large measure by the manufacturers themselves. Parts makers are laying in supplies of materials and the producers of complete vehicles do not propose to be caught napping.

Practically all the automobile factories in the country are closed at this time for inventory taking. Most of them have announced that they will reopen this week or next. It is possible that the period of idleness may be extended, but there is no reason to believe the action of Henry Ford in keeping his enormous plants down until Feb. 1 is symptomatic

(*Continued on page 41*)

New York Dealers Do Not Fear Future

Sales Slack in Holiday Period but Car Shortage Feared in Spring

NEW YORK, Dec. 31.—Automobile sales were practically at a standstill in New York as the year closed. In some lines the month had been fairly good up until Christmas when business dropped off as it always does just before the show—and perhaps a little more so. One or two big factory branches report almost no sales, wholesale or retail, in the final week of the year.

Dealers, however, are showing no signs of lack of courage and are going ahead with extensive advertising plans in connection with the show. Opinion is unanimous that the show will start business, which will show a steady gain until spring. Several distributers declare a shortage of cars in the spring is inevitable unless the public shows an unexpected willingness to accept some of the used cars now glutting the market. In fact, the abundance of used car offerings is an obstacle to new car sales right now, as most of the dealers are declining to do much trading and a large majority of new car prospects are standing firm against purchases with their old cars left out of the transaction.

Business in light trucks is better than it was, which is accepted as a healthy sign of returning business in all lines. Heavy duty trucks are selling very slowly.

BOSTON

BOSTON, Dec. 31—Sales conditions in Boston have improved. The dealers have looked the facts in the face and decided to get down to earth and try what real salesmanship could do. They are selling cars again, not in big quantities, but they are doing some business. Dealers have held conferences with their salesmen and mapped out campaigns instead of sitting down waiting for customers. Salesmen now are calling upon people and talking motor cars like the men who sell insurance, mortgages and other things that are not peddled out over a counter, with the result that those who tackled the job first are getting somewhat ahead of those who lagged behind.

Some of the dealers have been going along doing a very fair business, others pretty fair and more of them very little. There has been a picking up in used cars and trucks also, and it begins to look now as if the new year would see sales slowly increase.

Industrial Centers Best Markets

Slump Crest Past, Detroit Believes

Dealers Feel Sales Stimulation—Continued Upward Trend Expected

DETROIT, Dec. 31—The crest of the slump has been passed is the opinion of a majority of dealers as indicated in the December improvement over that of November. Following are reports by the Packard, Hupmobile, Dodge and Overland distributers.

Simons Sales Co. (Overland) says September was 10 per cent better than last three years; October was 5 per cent better than the last three years; November was 48 per cent less than the last three years and December to date 100 per cent better than November. Guy O. Simons, the president, says that there are more orders on file for delivery in January, February and March than ever before.

H. W. Peter, general manager of the Packard branch sales, said last week was not as good as the same week in November, but prospects for an increase in January will be good followed by a greater increase in February and there will be a big business in March. Summing it all up, Peters said the greatest trouble the Packard Motor Car has, is their used car problem. Every prospect wants to dispose of their old car before taking a new one.

S. E. Comstock, general manager, and T. J. Doyle, Dodge distributer, report an increase in December of 33-1/3 per cent over that of November and $18,000 more in revenues from used cars delivered in December than in those traded in. Doyle sold 47 used cars in November. The wholesale business is not so good because the upstate dealers are having trouble with the local banks. Reports from dealers and salesmen indicate marked improvement in January, to increase in February and begin real business in March.

Williams & Hastings, Hupp distributers, said December was not so good as November, but December is always the worst month in the year and prospects for January show marked improvement which will be steady until spring when the demand will exceed supply.

INDIANAPOLIS

INDIANAPOLIS, Dec. 31—Conflicting opinions of various Indianapolis retail dealers make it impossible to come to any definite conclusions as to immediate future of the local automobile business. Conditions are stationary at present—just about what they have been for some time past with no immediate prospects of a radical change. Cars are being sold at about the same rate as for the past few months. The open fall and winter undoubtedly resulted in stimulating the market for open cars.

BUFFALO

BUFFALO, Dec. 31—The outlook for the automobile business in Buffalo and the surrounding territory during the next three months is decidedly encouraging according to Buffalo's foremost distributers who declared to-day that the number of live prospects is gratifyingly large, that interest by potential buyers is much keener than it was and that an increasingly large number of inquiries are coming in.

CLEVELAND

CLEVELAND, Dec. 31—The retail automobile trade in Cleveland reached its lowest point approximately 30 days ago and the dealers assert there has been a gradual improvement since the early part of December. The trade is much better now than it was in November and the Christmas shoppers boosted business. Some retail business is better in Cleveland than in the district outside of the city.

There has not been a sharp rise in the volume of buying from retailers here, but a slow and moderate growth with enough inquiries to lead dealers to believe that there will not be a backward tendency.

PHILADELPHIA

PHILADELPHIA, Dec. 26—Actual selling conditions here show a slight upward tendency in new passenger cars and somewhat more decided impetus in used cars. Truck sales are dull and accessories are not moving to any appreciable extent. This division of the industry appears to be the worst off unless it is the tire trade.

It cannot be said, however, that there is any recessional movement here as regards the automotive industries. Summing it all up, there is only a little improvement altogether, but this is sufficient with the promise held out of more than usual interest in the passenger car show from Jan. 15 to 22 to cause optimism in the trade not only for the next three months but thereafter.

Kansas City Getting More Calls for Cars

Retail Sales Steadily Increasing —Public More Ready to Spend

KANSAS CITY, MO., Dec. 31—Wholesale distributers of passenger cars are receiving more calls for cars. They report that business is already picking up and gives promise of much expansion shortly. Retail sales in Kansas City have steadily increased during the past few weeks and would be much larger if dealers were willing to make more trades. Nearly every dealer has had more inquiries. One dealer in a moderate priced car said he would have a retail trade above normal if he would take in more used cars. Another dealer in moderate priced cars has had a fair business in new cars, selling a number normal for this season, and a really good business in used cars. Several sales a week are being made by some dealers in higher priced cars.

There is a perceptible relaxation in the public's resistance to spending money, which is being stimulated by the cut price sales in department and clothing stores. Many thousands of people here had made up their minds not to buy anything until after Christmas or after the first of the year and it is believed that when business men take inventory, when salaried men find out whether or not they still have jobs after the first, and people know how they are entering the new year, all business will be more stable and more lively, even though some weak merchants and distributers, not referring to the motor car industry, have to liquidate.

An unusually large proportion of the sales this winter have been to women and most dealers report an extraordinarily large number of women being taught to drive.

MILWAUKEE

MILWAUKEE, Dec. 31—State representatives of automobile companies here are showing increasing orders for spring delivery about 10% above that of a year ago. Local dealers are wrestling with problems of how to dispose of used passenger cars and have thus far been obliged to decline many tempting trades involving new sales. Business is always slow at this time, however, especially on open used cars.

Several dealers are planning special advertising and selling campaigns in

(Continued on page 40)

Buying Is Slack in Farm Districts

South Not Looking for Recovery Soon

Does Not See How Money Can Become More Plentiful Before Next Harvest

NEW ORLEANS, Dec. 31—Retail automobile sales conditions here are almost at a standstill and the upward impetus given by the pre-Christmas show seems to have died out within a week after the show closed. The majority of the dealers admit they have more cars, either in warehouses or in depots, than they can sell. Dealers in cars whose makers reduced prices report that there is some movement in Louisiana, Mississippi and east Texas, but in this city conditions are dull. This dullness is largely due to small receipts for sugar, rice and cotton crops, but dealers profess to believe that after the end of January, when the farmers know more definitely what they are going to get for their crops, business will be better.

The prices for all staple crops, as well as for seafood products and lumber, on which this State's business prosperity depends, are very low to the producer, while labor is high, and it is difficult to foresee just how money can be any more plentiful before another harvesting season, which will be next fall. Dealers in the highest-priced and lowest-priced cars seem to be having a little the best of the automobile business, the middle-priced car doing the least business.

AUSTIN

AUSTIN, TEX., Dec. 31—Automobile dealers in the Austin territory, as well as throughout the cotton growing region of Texas, are feeling the depressing effects of the slump of cotton prices and the consequent slump in general business. Farmers are placing orders for very few cars at this time, a condition that the trade has not felt for several years. Merchants and other business interests dependent to a greater or less degree upon the prosperity of the farmer are likewise holding off in buying cars.

No early improvement in conditions is expected. On the contrary, the crisis has not yet been reached, according to the views of bankers. It is stated by retail dealers that deliveries they are now making are of cars ordered some time ago. There continues to be considerable buying of cars, but chiefly of the cheaper type, which are essential to certain lines of business. Most of the orders come from professional and business men who have not yet felt the effects of the big drop in cotton prices. Little hope is held out that trade conditions will improve during the next three months unless there should be a material increase in the price of farm and range products, which is regarded as unlikely. It is estimated that of the 4,200,000 bale cotton crop which Texas made this year more than 2,000,000 bales are still in the hands of the farmers.

Los Angeles Enjoys Normal Winter Sale

LOS ANGELES, CAL., Dec. 31—Automobile selling conditions in southern California are normal. Both passenger cars and trucks are accumulating and being warehoused, but this has been the history of the industry at this season for years. When dealers in other sections of the country stop deliveries, factories always seek an outlet here, due to climatic reasons, and usually make an extra inducement to the dealers to stock heavily, and unless changes in models are likely the dealers usually comply, so there should be no alarm felt over heavy stocks now on hand.

The Los Angeles bank clearings for 1920 will reach $4,000,000,000, against $1,500,000,000 in 1919. The banks here have rediscounted less paper than those in any city of similar size in the country.

According to reports prospects for automobile business are to be regarded as favorable. December may show a slight falling off in sales, more so than in November, but not in an alarming way. Indications for the next three months show that sales will prove as good as in previous years, January and February usually being light months. November saw more sales than October and only 203 less than September and 19 less than August. The dealers could stimulate the new car business remarkably by loosening up on trade-in allowance, but the used car market is glutted and sales are very poor.

DALLAS

DALLAS, TEX., Dec. 31—There has been no business depression so far as the automobile dealers of Dallas are concerned, nor do indications point to any slack selling period for the next several months. This section of Texas is prosperous and the people are buying more automobiles than ever before, the dealers declare. A new idea was developed in Dallas and other Texas cities during the holidays and that was buy a car for Christmas, and many of them went as Christmas gifts.

Since the recent reductions in prices were made the dealers have enjoyed the

(*Continued on page* 40)

Northwest Buyers Want Cars; No Cash

Sales Practically at Standstill Because of Low Prices for Crops

MINNEAPOLIS, Dec. 31—Summarizing the northwest territory as a whole, automobile business is practically at a standstill. Although locally in large centers there is an improvement in sales, the outlook for the next three months is not bright. The trouble seems to be that the farmer is paying for clothes and food at the same prices he paid six months ago but crop prices are lower and he is therefore holding his products.

The disposition of both the retailer and buyer seems to be favorable toward the purchasing of cars, but the bankers probably will not be able under the present financial conditions to help the deals through. The opinion seems to be that if 30% of the delivery of cars is made, dealers will be doing well. There is a possibility that in some spots December business will be better than that of November, but it is hard to find any bullish opinions. The sudden arrival of winter has reduced the late driving appreciably which will have unfavorable reflex action on the sales situation also.

PORTLAND

PORTLAND, ORE., Dec. 31—The new year means more to automobile dealers here than a few good resolutions. They expect it to mark the turning of a new leaf in business conditions that will affect all lines, the selling of automobiles included, although no sudden wave of buying is looked for the instant 1921 arrives. But the dealers believe it will mark the definite opening of a new era of better times. Probably the orders will not be numerous before mid-February or early March, but almost without exception they expect conditions to be on the upgrade from and after Jan. 1.

This will be in line with normal precedent. November and December always are dull months for the automobile trade in the Pacific Northwest. There always is a good buying trend in February and March. This year the Portland midwinter automobile show, Jan. 10 to 15, is an added factor.

While not many orders are expected from the show, it is expected to give a first-class prospect list from which buyers may be plucked in the spring. Conditions since Nov. 1 have been about stationary, with little buying.

Ford Shaken by Internal Strife

Three Officials Resign Positions

Klingensmith, Brownell and Turrell Sever Connections—Report Large Surplus

DETROIT, Jan. 3—Lack of harmony in the Ford organization, which developed a near rupture at the time of the sensational price cut, has resulted in the resignations of F. L. Klingensmith, executive vice-president and general manager of the Ford Motor Co.; L. H. Turrell, chief auditor, and Charles A. Brownell, advertising manager.

Brownell is leaving ostensibly on account of the health of his wife, but to a representative of AUTOMOTIVE INDUSTRIES admitted yesterday the fact that Charles Sorensen, general manager of Henry Ford & Son, and E. G. Liebold, private secretary to Henry Ford, practically were in control of the big institution.

Further information on the resignations of the three officials was not forthcoming either from Ford or others, though it was stated that the resignations of W. B. Mayo, chief engineer; W. A. Ryan, sales manager, and W. E. Knudson, production manager, had neither been tendered or requested.

It is believed Sorensen will succeed Klingensmith as executive vice-president and will be inducted before the weekend. Ford will devote more time to the Highland Park plant from now on it is declared, and will attempt with the assistance of remaining officials to end the reported chaos in the dealer organization.

The presence of W. C. Durant in Detroit gave rise to a rumor that he might join Ford but officials who would talk pronounced it as without any foundation. Ford was more determined than ever to go it alone, they said, because of the general comment that in the loss of Klingensmith the company lost its greatest asset since Harold Wills quit the organization after a disagreement.

Three Resignations Accepted

Liebold said there was nothing for him to say other than that he had been informed the three resignations had been accepted. He said no successors had been named to Klingensmith, Brownell or Turrell, but added the entire matter would be threshed out and settled in detail this week.

The friction appears to have resulted chiefly from the fact that Henry Ford has maintained his office at the tractor plant at Dearborn to the exclusion of the big Highland Park establishment, where 51,000 of his employees work, and as a result received his only information from the Highland Park plant through Sorensen and Liebold; neither of them in close touch with Highland Park conditions.

It is known that there was bitter opposition to the price slashing from Klingensmith, on whom fell the burden of getting the money when it was needed. Klingensmith and other executives took the position that Ford sales would not be increased by the price cut, and at the same time business for the other manufacturers practically would be killed, thereby adding to public unrest and panicky conditions. Events bore out their prediction. For one week after the cut, Ford sales jumped enormously, but immediately thereafter slumped. Ford dealers throughout the country are overstocked, and it is stated by an official there are 125,000 surplus cars on hand, approximately six weeks' output at the Ford schedule of 4000 a day.

Dealers Aroused by Changes

On the heels of the cut came the removal of territorial restrictions, which put Ford dealers in a most antagonistic attitude and resulted in a chaotic condition in the dealer organization. At the same time the protective clause on prices was lifted, still further endangering the position of the dealers and adding to their already heavy burden. Under conditions as they exist to-day, Ford can cut his price over night and the dealer, with his warehouse and salesroom full of cars, has no protection whatever. He must stand the loss, whereas in the past the thirty-day clause in the dealer contract gave him full protection.

The slump that followed the price cut after the first week, in the opinion of Highland Park executives, made it imperative that the production be curtailed or stopped temporarily until the dealers could unload. Instead, the order went forth to speed up. As a result October proved a record-breaker, from a production standpoint, the company turning out 99,967 cars and trucks. The November output was 93,000 and the December total was 73,000.

In the face of this enormous production, and the fact that dealers already were heavily overstocked, came the official announcement that the company would shut down Dec. 24 to reopen again Jan. 3. Orders to parts makers, who had been closed, were to get into production Monday, Dec. 27, to prepare for the opening of the Ford plant.

Meanwhile the question of finances began to loom, for the reason that there were unpaid dealer drafts amounting to $12,000,000 outstanding, and it is said Klingensmith, whose chief duties lay in

(Continued on page 44)

American Dunlop To Finance Self

Negotiations Are Opened With Bankers in Which British Company Takes Part

LONDON, Dec. 24 (*Special Correspondence*)—Directors of the Dunlop Rubber Co. have reached the conclusion that the time has come for the American Dunlop Co. to finance itself and negotiations to this end now are under way. There has been some perturbation among the stockholders of the British company over the position of the corporation, and to allay apprehension, the directors issued the following statement:

"Within the past few weeks the company has been called upon to assume the responsibility of providing the additional finance required to place the American Dunlop Co. in a position to complete the construction and installation of its factory and to provide sufficient working capital to enable that company to carry out its first year's trading program.

"While the Dunlop Rubber Co. is under no liability to provide this additional finance, the board recognizes that it is in the interests of the company that the American enterprise should be carried on, and in accordance with the statements made at the last meeting of shareholders held on Sept. 10 last, the greater part of the sum of 1,000,000 pounds ($5,000,000) has been remitted during the last few weeks.

"The directors, however, feel very strongly that the American company should now take steps on its own initiative to provide the further funds required to bring the undertaking to completion, and important negotiations, in which this company is assisting, are now pending for this purpose, but it is not expected they will reach finality for several days. The moment a definite statement on the subject can be issued, a full circular will be addressed to the shareholders of the Dunlop Rubber Co. dealing with this matter and with the position of the company generally."

BRAZIL KEEN ON FINES

WASHINGTON, Jan. 3—The Chamber of Commerce of the United States has sent out a warning to American shippers telling them that unless all regulations regarding Brazilian consular invoices are rigidly observed, they result in fines being imposed on consignees in Brazilian ports. It is explained that custom house officials in Brazil receive 50 per cent of all fines levied on consignees taking their wares from custom houses This encourages fines for the slightest deviation from invoice regulations.

DALLAS

(*Continued from page* 38)

best business of years. From the inquiries the dealers are having concerning new models or new cars it would appear a good business in the Dallas territory is assured for the coming year. Dealers say the car priced at from $1,800 to $3,000 is the favorite now. Heavy orders are being placed and the dealers are in a position to care for the business without any great assistance from the bankers.

ATLANTA

ATLANTA, Dec. 31.—Several dealers to-day expressed confidence that business would pick up considerably after the first of the year, but the consensus of opinion is that there will be no return to normal conditions for several months unless cotton should climb to price that is double the present quotation. The holiday business is fairly good considering the recent period of depression and the dealers state many prospects promise to buy early.

In 1921, if all these sales develop, the dealers say the demand will exceed the supply. The next two or three months will witness only the beginning of return to normal conditions, which dealers do not believe will fully materialize before late spring or summer. Very few sales are being made now, and it is certain the trend will not be backward, for money is becoming less tight and the dealers say this will mean slow but gradual increase in sales from now on. All business lines are doing everything possible to restore public confidence.

DENVER

DENVER, COL., Dec. 30—Although many dealers are still gloomy over the present conditions. others point out that December is usually a dull month and some have had reasonably good business during the month at that. The upward trend has already been felt by few during the last few days through sales and prospects, and there is substantial confidence of a gradual gain during the next three months, particularly February and March. Please tell Adair that the selling story is delayed because Heiser is sick, but hopes to give me an interview early next week and has by far the best record in Denver sales right now.

CINCINNATI

CINCINNATI, Dec. 31—Automobile dealers in the Cincinnati territory are optimistic over the prospects for the automobile industry in the future and are confident that business will begin to pick up after the first of the year. This increase is expected to materialize about February 1. From that date on sales are expected to mount so that the trend will be well defined before the end of March. At present there is some activity here but not much.

None of the dealers is figuring on anything like a big business for the regular 1921 season. They realize that the market is or will be glutted with used cars, purchased during last year's scrambles, and that prospects for new cars will necessarily be limited.

It is the opinion of some dealers and especially of manager H. K. Shockley of the Cincinnati Automobile Dealers Association that several manufacturers, who have curtailed their production, will actually find themselves "short" and will have to hold off prospects for a few weeks on deliveries when the business comes. These include dealers who are holding production to the minimum, unwilling to take a chance against the future until the business actually is at hand.

CHICAGO

CHICAGO, Dec. 31—No notable increase of sales of automobiles is evident in connection with the holiday purchasing of commodities and dealers are not in an expectant mood for immediate improvement. The reported increase in price of Franklin cars is expected to stimulate buying, which has been quiet for months, through the effect it will create on the public mind that other cars may likewise have their price values moved upward.

It can be said that show week is looked forward to with keen anticipation by all dealers as the real beginning for the return to normal in the automobile trade in this city. With that in mind every effort is being made to line up prospects now and have them ready when the coliseum opens. For the present, however, conditions remain unaltered generally from what they have been for the past few months. While there have been sales made they have not been made in such volume as to make the horizon any too rosy for the dealers.

New Air-Cooled Car Designed by Horning

CLEVELAND, Dec. 31—The Washington Automobile Co. of this city plans to produce a new air-cooled car to be known as the Washington Six from designs of Walter R. Horning, who was formerly engaged in the electrical equipment business. It will be an assembled car comprising such components as Timken axles, Delco electrical equipment, Borg & Beck clutch, Grant-Lees gearset and Thermoid Hardy universals. The engine is a six cylinder $3\frac{1}{4}$ x $4\frac{1}{2}$ inch overhead valve design and the wheelbase will be 120 in. A rear axle ratio of 4.66 to 1 will be used. Oilless bushings will be extensively used, and a Harrison ventilator will be fitted to vary the cooling effect in accordance with atmospheric temperature.

MILWAUKEE

(*Continued from page* 37)

January or February after the income tax period and are depending on the severity of the weather to sell for spring delivery on liberal deposit. Provided these plans get sufficient reaction, and it is expected they will develop formidably though intensive salesmanship, business will truly open up on sane basis.

At several private conferences the dealers expressed decidedly more confidence in the next three months. They do not expect a boom period but do expect a response exactly in proportion to hard sales work. They declare that practically all owners who trade in annually and for new cars are anxious to get action as soon as possible, showing there is plenty of money among the present owners. Lower-priced cars are not expecting anything like the rush of two or three years ago, of course, but they feel sure they have a sound and healthy business which will more than make up for the reduction in boom volume.

Trucks are selling slowly and the tractors are not expected to revive for several months more. The public is still talking about further price reduction in all automotive lines but is impressed by their failure to get cut prices now. The dealers are all standing pat.

DES MOINES

DES MOINES, IOWA, Dec. 31—Automobile conditions are practically stationary in Des Moines territory. One distributor had twelve salesmen in the field during the entire month of December and they failed to bring in a single order for immediate delivery. The prospects for spring business are good but little business is expected the next sixty days. To show the trend during the past sixty days, of 1000 registrations issued in 25 counties in Des Moines territory, more than 800 were for Fords. Relief from present conditions is dependent upon the credit situation. In the farm produce market there are signs that the movement of grain has started and this will tend to improve the situation, but it will be slow.

HENDEE BUILDS POLICE CARS

SPRINGFIELD, MASS., Dec. 30—The New York police department has bought of the Hendee Mfg. Co., eighty-eight motorcycles and side cars for use in the suppression of the crime wave in that city. The motorcycles will be equipped for patrol duty, to carry driver and passenger heavily armed. It is believed that the free use of motorcycles will be effective in dealing with automobile bandits. The same corporation has received large orders from Boston and Philadelphia, making a total of 221 motorcycles and 153 side cars ordered for these three cities.

Automobile Sales at Retail Spotty

Dependent Chiefly on Local Business—Little New Discussion on Prices

(*Continued from page* 36)

of the industry as a whole. Ford produced at top speed all of last year and probably has a considerable surplus on hand. A few other manufacturers are in the same position.

Except for the announcement that Franklin will raise his prices slightly, there has been little discussion of late of the price question as it relates to finished cars. In this respect there seems to have been more or less stabilization. It may be significant, nevertheless, that manufacturers of parts and accessories are announcing reductions. The expectation in some quarters is that companies which gave price guarantee in lieu of reductions may announce readjustments during the show. Much importance is being attached to the sales stimulation which will result from the New York and Chicago exhibitions, and everything possible will be done to extract from them every possible benefit to the industry.

Production to-day is at a low ebb, but the outlook is more hopeful than it has been in six months. Sales very largely depend upon the stabilization of retail prices in general at more normal levels and there are many indications that retailers in various lines are resigning themselves to the inevitable and are preparing to pass on to the ultimate consumer some of the substantial cuts which have been made in retail prices.

FORT WAYNE PLANTS CLOSE

FORT WAYNE, IND., Dec. 31—The Dudlo Mfg. Co. of this city has closed down all its departments which were engaged in the manufacture of products used by the Ford company. About 700 employees have been thrown out of employment indefinitely by this shutdown, this number including 75 employees in the New Haven branch and 30 employees in the Peru branch. The Dudlo company manufactures insulated wire. About 300 employees engaged in the manufacture of products which are not used by Ford still are at work.

The Harry Andrews Paper Co. of this city has also been affected by the Ford shutdown. The Andrews company supplies Ford with a paper composition used for the inside doors of Ford cars.

COMPLETE HIGHWAY LINK

MASON CITY, ILL., Jan. 3—The largest stretch of paved road which has yet been completed under the Federal Aid Act, has been formerly dedicated. It constitutes a link in the Chicago—St. Louis highway extending from Sparland to Chatham, a distance of 117 miles. The entire road is paved with concrete and it passes through Springfield and Peoria.

STUDEBAKER QUITS WAGON MANUFACTURE

SOUTH BEND, IND., Jan. 3—Manufacture of the famous old Studebaker line of wagons will be discontinued and the entire facilities of the Studebaker plant here will be devoted to the production of motor cars. Some time ago the carriage and harness ends of the business were closed out, but the manufacture of farm wagons and heavy vehicles for army purposes was continued until the present time.

Newark Factories Cut Down Operations

NEWARK, N. J., Dec. 31—A survey of important plants in this section of New Jersey indicates an almost complete stoppage of production in many cases, while other firms are simply holding together skeleton organizations.

Hyatt Roller Bearing Co. shut down on Dec. 24th and expects to resume production Jan. 3. An announcement to employees stated that all departments will resume at the same time, but with forces of a size proportionate to production necessities at that time.

Splitdorf Electrical Co. is holding together its office and shop organizations, but has reduced production very materially.

After a two-weeks shutdown, Gould & Eberhardt will start production again on Jan. 5. A force of 270 men will be put to work at that time, and gradually increased as necessity demands. The working force at this plant numbers about 900 under peak-load production conditions.

In contrast to the generally depressed situation in this district, the Rubber & Celluloid Products Co., which employs about 80 men, is maintaining its working force intact, although some decline in volume of business has been experienced.

TO USE NEW RAUSIE ENGINE

SPRINGFIELD, OHIO, Jan. 3—The Martin Aircraft Co. of Cleveland will equip one of its large commercial airplanes with a Rausie Big-Six engine of 250 hp. A new design of engine with four valves per cylinder and double camshafts will be submitted to the Government for the air mail service. This engine will be equipped with an electric starter.

A CORRECTION

Hanson & Tyler Co., Fort Dodge, Iowa, which has made an assignment to creditors, was not agent for Chandler and Cleveland cars as was stated at the time the assignment was announced. These accounts with the Hanson-Tyler company were closed April, 1919 and since that time have been in other hands.

Excise Tax Refund Sought in Canada

Deputation of Dealers Request Return of Money on Unsold Cars

OTTAWA, Dec. 31—A deputation of Motor car dealers, 400 strong, coming from all points in Canada, from Vancouver to Halifax, waited on Sir Henry Drayton, Minister of Finance, to urge that the excise tax paid on unsold cars in stock at the time of the recent repeal of the excise tax be refunded.

In the brief presented on their behalf by E. M. Trowern of Ottawa and supported by G. M. MacWilliam of Toronto, and J. H. Fortier of Montreal, it was pointed out that in collecting the excise tax on motor cars at their Canadian source (point of manufacture or port of entry of domestic manufactured and imported automobiles respectively), the motor car dealers were discriminated against, as this procedure not only aggravated the already difficult credit situation, but also militated against sales during the life of the excise or so-called luxury tax.

This adverse discrimination unfortunately, like the "evil men do," survives the tax in a much more grevious form, for while on clothing, shoes, jewelry, etc. (collected by retailers at the time of sale) the tax was automatically dropped at the time of the repeal, it remains on motor cars that were in dealers' stocks at that time, as a result of which the dealers must take it as a loss.

The tax, 15 per cent on cars under $3,000 and 20 per cent on cars at $3,000 and over, in many cases approximately equals the dealers' profit. It was further pointed out that owing to the buyers strike and credit stringency, the loss a large proportion of dealers would be compelled to face was beyond their power of absorption. Consequently many would be bankrupted and others would be paralyzed. Some dealers stand to lose as high as $60,000 on the tax alone unless it is refunded.

LABOR NEARS PRE-WAR BASIS

HARRISBURG, PA., Dec. 31—Reports to the central office of the Pennsylvania State Employment Bureau are said by the officials to indicate that labor of all kinds is rapidly returning to its pre-war status and the Pennsylvania labor turnover is decreasing. It is believed conditions will be back to normal in virtually all trades in January.

HAYES WHEEL STAYS DOWN

DETROIT, Jan. 3—Hayes Wheel Co. at Albion, which had been closed for about two months and which was reopened Monday, was closed again Wednesday following the announcement that Ford would not reopen. The company manufactures hubs for Fords almost exclusively.

Goodyear Passes January Dividend

Statement Declares Impairment of Capital Made Action Unavoidable—Add Directors

AKRON, Jan. 3—Explaining to stockholders that the present impairment of capital made its action unavoidable, the Goodyear Tire & Rubber Co. passed its quarterly preferred dividend which fell due Jan. 1, at the same time issuing an official statement to the effect that preferred dividends, being cumulative, would be paid before any further dividend is paid to common stockholders.

Announcement of the company's action was made following an adjourned meeting of stockholders at which several changes in the company's code of regulations were voted. Principal among these changes is the decision to increase the number of directors from seven to eleven. Stockholders also ratified change of the fiscal year to correspond with the calendar year instead of ending on Oct. 31; voted to hold the annual meeting in March instead of December, and empowered officials of the company to create finance and executive boards.

In announcing the company's inability to declare the usual preferred stock dividend, officials in formal letters to stockholders said:

"Your disappointment in not receiving the quarterly dividend on the preferred stock held by you, due on Jan. 1, 1921, is no greater than that of your board of directors in not being able to pay the same on that date. The plans for the refinancing of our company, which we expected to have fully completed at the time of the first adjournment of the special meeting of stockholders several days ago, are not yet fully consummated. Until these plans have been completed and the present impairment of the company's capital, as shown by the audit made as of Oct. 31, 1920, and which was presented to stockholders Dec. 29, has been restored, the company would have no legal right to pay this dividend even though it had at present funds to do so.

First Duty to Creditors

"The company's first duty is to make satisfactory arrangements with its creditors before any dividends are paid to the stockholders.

"These dividends are cumulative and when payments are resumed all dividends in arrears on preferred stock will have to be paid before any dividend is paid to the common stockholders. We hope to announce in the very near future the completion of the plans now under way for the company's permanent financing."

The annual audit showed a deficit of $15,647,653 in addition to anticipated losses of approximately $19,000,000 on contractural obligations for rubber and fabric.

Much to the surprise of stockholders attending the adjourned meeting on Dec. 29, officials of the company were unable to announce definite and satisfactory consummation of the refinancing negotiations, and asked a second adjournment for two weeks in order to permit more time for carrying on the negotiations. It is understood in Akron that an eleventh hour hitch in the tentative negotiations arose, due to terms of the Eastern banking group expected to negotiate the loan to the extent of $40,000,000 or $50,000,000, which were regarded as too exacting by Goodyear officials.

Tried Other Financial Groups

This unexpected development, it is reported, caused Goodyear representatives to turn to other financial groups in the hope of pushing through the refinancing upon terms more satisfactory and acceptable both to officials and stockholders of the company. The permanent refinancing must be consummated by Feb. 15 to replace the temporary loan of $28,000,000 advanced through the Goldman-Sachs Co. of New York, and which matures on that date. There is a possibility of extension of this loan, officials state, should the permanent refinancing plans be further delayed.

In casting about for new and more friendly financial interests to tide the Goodyear company over its present crisis, it is understood officials turned to J. Pierpont Morgan and the banking group represented by him. Latest available and tangible information received in Akron from Wall Street indicates that the company is experiencing considerable difficulty in interesting the Morgan interests in the refinancing venture.

Wall Street is known to be none too friendly to Goodyear, due to the fact that the company through the financial strategy, business ability and genius of its president, F. A. Seiberling, who in Akron is known as the "Little Napoleon," prior to this time has been able to carry on its previous refinancing without the aid of Wall Street, and therefore has declined proffers of aid from Eastern banking groups.

Called for Stock Control

The original terms, upon which the original banking group consulted, offered to absorb the Goodyear issue of $40,000,000 in first mortgage gold notes, are said to have included a stipulation that the financing group be assigned control of fifty-one per cent of the Goodyear participating stock during the tenure of the loan. This President Seiberling is endeavoring to avoid. The original terms also included a virtual mortgage on the Goodyear plant and a commission of 2½ per cent on net profits during the tenure of the loan, in addition to the interest charge agreed upon.

HARDMAN RECEIVER NAMED

NEWARK, N. J., Jan. 3—Vice Chancellor Foster has appointed Chester N. Farlie receiver of the Hardman Tire & Rubber Co. of Belleville. The application was made by the Rubber Importers & Dealers Co. of New York for a judgment claim of $3,336.

Franklin Completes Largest Sales Year

Production of 10,500 Represents 1500 Increase — December Output Totals 1000

SYRACUSE, Jan. 3—Franklin Automobile Co. has announced completion of its biggest year and the establishment of several new records. Despite the almost complete let-down in selling during the autumn months the Franklin company has sold and delivered ten thousand five hundred cars during the year. Of this number one thousand have been delivered to customers for immediate use during the month of December. This is the largest December in the history of the company and is considered indicative of the growing popularity of the air-cooled car for winter use.

Figures for the entire output in 1919 were 9173 cars, of which number 828 were sold during December. December, 1918, the Franklin company sold 234 cars. The production schedule of the preceding years never approached the figures of 1919 and 1920. The largest single day's delivery during the past month was Dec. 29 when seventy cars were shipped. They were sent to all parts of the country and not to any distributer who contemplated storage for future delivery.

Harvester to Deliver First Light Trucks

SPRINGFIELD, OHIO, Jan. 3—Preparations have been made by the Springfield works of the International Harvester Co. to usher in the new year by delivering the new high speed trucks to the trade. The first truck will be placed on exhibition in the lobby of Hotel Shawnee, permission having been granted by Manager Charles T. Gauvey. The new truck will be shown at the Columbus show in January and at the Springfield show in February.

Preparations are being made to increase the force at the Springfield works to 3000 before the end of 1921. About 1200 men are at work now getting out the new trucks and working on bodies for the Akron plant.

WINTHER BUYS TRUCK CONTRACT

SPRINGFIELD, MASS., Dec. 30—The United States contract held by the Sinclair Motors Corp. of this city was obtained by the Winther Motor Co. of Kenosha, Wis., for $10,000, the sale being authorized by Referee Charles W. Bosworth at the adjourned meeting of the Sinclair company creditors in bankruptcy court here. The deal was negotiated through the trustee in bankruptcy of the Sinclair Motors Corp. It was reported by Referee Bosworth that the contract carries with it all of the assets of the Sinclair company intended for use in constructing the trucks.

Factories Resume on Low Schedules

General Operation Still Month or More Away—Wages Cut 20 Per Cent

DETROIT, Jan. 4—Between 8000 and 10,000 men went back to work in automobile factories here yesterday and today. While it is the plan of the manufacturers to increase forces and production steadily it is admitted freely there will be no real resumption for a month at least.

Wage schedules in all plants which reopened yesterday have been cut around 20 per cent, but no complaint has been received and workmen, after weeks of idleness, are apparently eager to return at the reduced scale. The stopping of the Ford and Dodge plants simplified the wage problem and plenty of labor is now available at a reasonable wage. Best of all, manufacturers say, the returned workmen are full of pep and are apparently ready to give full return in service despite the wage reduction.

It was stated unofficially that the Dodge plant will be down indefinitely. General Manager F. J. Haynes declined to predict the date of resumption or the schedule likely to be in effect on reopening. Practically the entire force of 22,000 men are off, though a few hundred have been given work cleaning and overhauling the plant and parts department. Dodge continued to have a heavy output in October and November. Dealers are heavily overstocked and thousands of cars are stored.

Cadillac is still taking inventory and will not get back to production before next week, according to Lynn McNaughton, general sales manager. He declined to say how many men will go back next week or what the output would be.

Packard reopened yesterday with about 50 per cent of the regular force. Officials say they will increase the force as circumstances warrant. Production will be confined to closed jobs on the single six chiefly and only in keeping with demand.

Studebaker Starts 400 Men

Studebaker opened plant No. 5 yesterday with 400 men. They are getting the plant in shape for resumption of production next Monday in all the company's units as announced before the holidays. They will start on a schedule of 90 cars daily for all plants, increasing as conditions warrant.

Paige-Detroit began taking back married men yesterday and hope to get back into production as soon as the plant is in shape, probably by the end of the week. They will maintain a rate of 25 cars daily with about 1000 men working temporarily. The company has orders for January delivery totaling $2,000,000 and for February of $2,500,000. This, with the daily demand expected, will permit an increase to 35 cars daily by Feb. 1. A survey of Paige dealers on Dec. 1, according to H. C. Dart, advertising manager, shows fewer cars unsold in the country than the actual number of Paige dealers.

The Lincoln Motor Co. has about 200 men at work though not attempting to produce any cars. All its efforts are being centered in the parts departments. It expects to swing into production next week, though officials have not announced the schedule.

Chalmers to Start Monday

Officials of Maxwell-Chalmers say the Chalmers plant will open next Monday with about 300 men working on closed cars of both types.

About 75 men went to work at the Columbia Motor Co. yesterday in the parts department and they are getting the plant into shape for resumption of production. The date of starting has not been decided.

Other plants are still down so far as production of automobiles is concerned, though the parts departments in all factories are being operated except in the case of Hudson and Hupp which did not stop for inventory, continuing on the curtailed schedule in vogue the last two months.

The Essex plant is closed but both Hudson and Essex cars are being built in the Hudson plant at the rate of about 15 daily. Hupp is continuing its schedule of 35 maintained since Dec. 1.

Buick will get under way next Monday and will continue indefinitely the daily schedule of 250. Dort will not get started on its new model probably until the end of the month and Oakland and Olds expect to start next week with a short force and their output limited to the demand in sight, though a schedule of 100 for Oakland and 30 for Olds will be the starting figure. Reo has resumed production but is continuing on a short time schedule and building about 30 cars daily. Chevrolet will get under way by the end of the week on a production of 100 a day to be increased as demand justifies.

Finds Country Stocks Down to Low Point

NEW YORK, Jan. 4—David Ludlum of the Autocar Co. was here to-day to visit the truck show and incidentally to impart as much optimism as possible to all he met. Ludlum came to New York from a two weeks' vacation in upper New York State, where he visited many country merchants. He had with him the December sales reports of his company. His optimism was founded on these two incidents. He said:

"I firmly believe that we are beginning a very big year. During my trip I have visited many country merchants. I found that they were so down in stocks that they could not supply the wants of their trade and they all are realizing that they must order goods and order them quickly. They believe that present wholesale prices are as low as can be expected. I predict good merchant buying at once and that it will be widespread.

Akron Begins Work on New Schedules

Goodyear Cuts Factory Wages and Salaries—January Orders Substantial

AKRON, Jan. 4—The Akron rubber companies resumed operations on Jan. 3, after being closed for the Christmas Holiday week, with every indication pointing to considerably increased production. There is a gradual absorption of Akron's estimated army of 20,000 unemployed men and a steady return to conditions approaching normal in the tire industry. Goodyear wages will be cut 12½ per cent Jan. 10, and all salaries from 15 to 20 per cent.

It is stated authoritatively by Akron manufacturers that Akron rubber and tire concerns start the new year with fully $50,000,000 worth of new business on their books so far for the month of January. This estimate is conservatively made and is likely to be exceeded largely when all January orders are compiled.

This, according to business experts, is the most encouraging note in the tire industry that has been sounded since the period of retrenchment began last summer. It is not taken to mean, however, that the $50,000,000 worth of business will result in increased production at once, but is taken to augur well for an early resumption of operations.

Practically all companies have surplus finished product on hand sufficient to accommodate January orders, but with orders continuing to increase as they have since Dec. 15, it is stated that this surplus rapidly will be worked down and will demand greater production at least by Feb. 15 in order to keep production apace with demand. The Goodyear company on Dec. 15 had over $10,000,000 worth of business booked, with over $5,000,000 more in new January orders received. Since that time other companies show commensurate amounts of January business.

The B. F. Goodrich Co. on Monday increased factory operating time, and put on many former employees for the first time in eight months.

Firestone on Firm Basis

The Firestone company is understood to be more sound financially than any other concern in Akron and to be prepared to increase production just as soon as the present surplus is worked down by deliveries on early 1921 orders.

The Goodyear company's business is coming in to such extent as to indicate an early necessity for increased production, but under the present temporary financing program, there is no possibility of the present payroll being increased. Should the Goodyear permanent refinancing replace the temporary loan of $28,000,000 which matures Feb. 15 be consummated before the next adjourned meeting of stockholders, officials hope to be able to increase production.

Ford Organization Shaken by Strife

Three Officials Resign Positions —Plant Down Indefinitely, Officials Declare

(*Continued from page* 39)

the financial end, then took the position that resumption of operations would be unwise until the big surplus of cars had been unloaded.

A long conference last Wednesday resulted in orders to parts manufacturers who had resumed operations Monday again to stop production for Ford indefinitely, and some of them, notably the Hayes Wheel Co., at Albion, which makes Ford hubs exclusively, promptly closed down after three days' operation following a shut-down of six weeks. At the same time orders went forth that the factory would remain closed indefinitely —certainly until Feb. 1. Officials said to-day there would be no resumption before Feb. 15 in any event, and most likely the shut-down would continue some time after that date.

Just what action took place with regard to the resignations at the conference Wednesday is not known. It was followed, however, by an all-day session Thursday, and Friday morning Brownell announced his resignation. He later gave out the statement regarding Klingensmith and Turrell together with the facts which brought about the crisis.

Brownell has been with the Ford company since 1914, prior to which time he had handled Ford copy in the firm of J. Walter Thompson Co. When he joined the organization the company was building 38,000 cars a year. The output for 1920 was 1,023,552. Brownell had been contemplating a trip to California for the health of his wife, though his plans were simply to take her to Los Angeles, where he owns an estate upon which his daughter resides, and leave her there for a time, returning to his duties in Detroit. His resignation, however, he said to-day, would give him opportunity to spend three months in the West.

Turrell Regarded as Fixture

Turrell, formerly an expert accountant, has been with the Ford company nine years and, as the head of the accounting department, had actual charge of Ford finances, incoming and outgoing. He was regarded as one of the Ford fixtures. It is said Ford plans to abolish this position.

The resignation of Klingensmith, however, was the one big topic in banking circles and among automotive executives. Starting in as a bookkeeper with Ford about sixteen years ago, Klingensmith rose to the position where he was presumed to be head and shoulders above everyone else in the organization. He succeeded Mayor James Couzens as executive vice-president and general manager, and much of the success of the company is attributed to his efforts. The fact that he denies his resignation is regarded in the light of a technicality, because he insists on the request coming from Henry Ford rather than Liebold or Sorensen, and his official announcement of his resignation is expected later.

Willys to Maintain Present Car Models

TOLEDO, Dec. 31—C. B. Wilson, new vice-president of Willys-Overland Co., in a statement this week declared the automotive industry would be one of the first to right itself from the present depression. Local troubles, he said, threw the Willys-Overland plant out of balance and declared it would take some time to put the plant back on the basis desired by the owners, but assured Toledo that it would not be long until it would be in operation.

"There is no doubt of the well-laid plan of the Overland officials to operate on conservative lines on an economical basis. The product has been studied carefully and executives are laying plans for the future. There will be no new models brought out in 1921.

Resume on To-Order Basis

NEW YORK, Jan. 4—Production at the Willys-Overland and Willys-Knight factories will be continued strictly on a "to-order" basis. No cars will be made in anticipation of demand for the present. Relative to the company's policy, Vice-President Chrysler said:

"We have materially reduced our outstanding obligations and have followed the policy of liquidating finished product. As a result our stocks in the field are very low and the total number of finished cars that we have at our warehouse in Toledo is less than 2200. Two weeks of business throughout the country would completely absorb every finished car."

EMERSON PASSES DIVIDEND

ROCKFORD, ILL., Jan. 4—At the annual meeting of the Emerson-Brantingham Co., it was voted to defer action until the next meeting upon the resignation of J. W. McLachlan, secretary-treasurer. The quarterly dividend was passed, the following explanation being submitted: "Owing to the general trade and financial conditions, the directors of the Emerson-Brantingham Co. deem it advisable to maintain the company's finances in the strongest possible position, and, consequently, voted to omit the declaration of the regular quarterly dividend which would be payable Feb. 1, 1921, although the earnings of the company for the fiscal year, recently closed, were more than its dividend requirements for that period."

INDEX TO VOL. XLIII

Subscribers who desire a copy of the index to Vol. XLIII (second half 1920) can secure same by sending their name and address and a request for the index to this office.

South America Open for Continued Sales

Exchange Conditions Only Important Drawback to Big Opportunity—Roads Improve

NEW YORK, Jan. 3—A belief that American automotive manufacturers should not slacken their sales and service work in any of the countries of Latin-America was expressed here to-day by J. H. Wise, who has just returned from a business trip to Para, Pernambuco, Bahia, Rio de Janeiro, Sao Paulo, Santos and Rio Grande del Sur, Brazil; Montevideo, Uruguay, and Buenos Aires, Argentina. Wise, as a representative of Gaston, Williams & Wigmore, Inc., was placing agencies for the Peerless automobile and Selden trucks.

"Exchange conditions are the greatest hindrance to trade at the present time," he said. "But, due to the great natural wealth of these countries and the business betterment that may be expected in the coming months, this is no time to let up the slightest on foreign trade. Exchange with South America will return to normal much more rapidly than it will in Europe, and to one who has sufficient knowledge of the great territory of Brazil, Uruguay and the Argentine, there can be no doubt of the trade volume that we may expect in coming months.

"Service is a prime requisite for the exporter who expects to continue in the South American market. Now, when conditions are slackened here at home, is the time to undertake service and maintenance campaigns for the foreign field. Service literature is needed, education is required—all of which should be undertaken by the North American automotive manufacturer who would extend his business in the Spanish and Portuguese speaking countries."

Sao Paulo Market Promising

Wise sees the Brazilian state of Sao Paulo, the center of the coffee-growing district, as one of the most promising fields for automotive sales. The city of that name, which is the capital of the State, is the third largest in population in the South American continent and already boasts of some 4000 automobiles. An improved road is now being built to the city of Campinas, which has a population of 150,000 and is located 105 kilometers to the north. The completed highway to Santos stands as an example of fine highway construction, and Wise reports an active project for the construction of an improved highway to connect Sao Paulo with Rio de Janeiro.

The touring car predominates in Sao Paulo, there probably being more five-passenger machines than any other design. But, as Brazilian families are apt to be large, there is a steady demand for seven-passenger models. The sale of cars with limousine bodies is not large, but among those who can afford them, this type is popular. The demand for sedan or similar enclosed cars is small.

France Gets Bill to Quash Gas Tax

Would Help Lift Industry from Slump—New British Tax in Effect

PARIS, Jan. 3—(By cable to AUTOMOTIVE INDUSTRIES)—A bill has been brought before the French Parliament calling for the abolition of the state tax of 20 centimes a litre on gasoline on a caloric basis. This is equivalent to a tax of $35 a ton on coal and is responsible in large measure for the present slump in the automotive industry. In February Germany will begin delivery of 35,000 tons of benzol a year in accordance with the terms of the peace treaty. It originally was intended to use this mixed with alcohol as automobile fuel but no alcohol is available, owing to the decrease in production. The Government now proposes to sell most of this benzol at cost to the French chemical industry and the rest will be put on the market. The automotive industry would have preferred to have all of it go on the open market in order to force down the price of gasoline.

The price of gasoline in England dropped 7 pence a gallon Jan. 1 but the 1 pound sterling horsepower tax went into effect at the same time.

A French law which went into effect Jan. 1 provides that no person can pilot an aircraft without a government license delivered after a thorough medical examination.

Swiss banks have advanced the funds necessary to continue the operation of the Piccard-Pictet. Liquidators have been appointed and it is probable the affairs of the company will be wound up.

The French Dunlop Co. has purchased the government shell factory at Mont Lucon, covering 250 acres and will use the property as a tire factory, but will not get into production until the end of 1921.

Dates have been fixed for the London automobile shows to bring them after the Paris exhibition. Trucks will be shown from Oct. 14 to 22 and passenger cars from Nov. 4 to 12.

A new tire company is being formed in Turin with a capital of $5,000,000. It is believed the Fiat Co. is financially interested.

Entries for the French Grand Prix, which closed on the last day of the year, were disappointing. They included only four Ballots, three Fiats, three Darracqs, two Sunbeams, two Talbots and one Mathis. Unless late entries are received at double fees it is doubtful whether the race will be held. BRADLEY.

Kelly Tire Reported Sought as G.M.C. Unit

NEW YORK, Jan. 5—The Kelly-Springfield Tire Co. has declared the regular quarterly cash dividend of $1 a share and the usual quarterly 3 per cent stock dividend on the common stock as well as the quarterly dividend of $2 a share on the 8 per cent preferred. Stock of the company has risen rapidly on the stock exchange in the last few days on reports that several new directors soon will enter the board and that control of the company soon will be shifted to the Morgan interests. This is coupled with assertions that after these changes are made Kelly-Springfield will become a unit of General Motors, which now has no tire factory although it has close relations with the Dunlop Tire Co. It has been impossible to obtain confirmation of these reports.

ROCKFORD TO AID COTTA

ROCKFORD, ILL., Jan. 3—Business men of this city have launched a campaign to save the Cotta Transmission Co., manufacturer of motor vehicle accessories, now in bankruptcy. Since the company's difficulties reached an acute stage, there has been a desire upon the part of the leading citizens of Rockford to prevent a suspension. Several manufacturers in other lines have offered to assist in a financial way and some of the preferred stockholders have also volunteered their co-operation.

It is the impression that the trouble is only temporary and that a little aid at this juncture will tide the company over the present embarrassment. It is planned to sell enough stock to realize funds to take care of the pressing obligations. A committee of five leading merchants has been appointed.

Exports for November, 1920, and Eleven Months Ending November 30

Car Exports Reach $274,597,092 Total

Figures to November 30 Double Previous Year—Imports Grow to $1,236,256

WASHINGTON, Jan. 3—Both exports and imports of automobiles and accessories showed a remarkable increase in the statistics of foreign trade, compiled by the Bureau of Foreign and Domestic Commerce for November. The shipments of American cars for the first eleven months of this year were valued at $274,597,092, as compared with $136,141,486 for the corresponding period last year. These figures show that the foreign trade in automobiles has more than doubled.

Imports, too, have grown with the passing of the months, indicating the rehabilitation of European car manufacturers. There were 853 automobiles entered at American ports in the eleven months ended November. The declared value was $925,669. For the same period in 1919, 107 cars valued at $100,781 were placed on American markets. The automobile parts manufactured abroad and sold here increased tremendously for the total value of the shipments for the eleven months of 1919 was $251,491, as compared with $1,136,256 for the corresponding period this year. The imports of these products for November, 1919, were valued at $79,584, as against $107,264 for November, 1920. Nineteen cars, valued at $58,054, entered this country in November last year and sixty-six cars, with a valuation of $67,272, were imported for the same month this year.

The 4917 cars manufactured in this country and returned for various reasons were valued at $7,855,499. This eleven months' total is large, for in the same period last year 1497 cars valued at $3,199,675 were returned. Part of this increase is perhaps due to returned army cars.

Harbeck Resigns from American Can

Will Confine Activities to Automotive Interests—Maxwell-Chalmers Position Good

NEW YORK, Jan. 4—J. R. Harbeck has resigned as vice-president and director of the American Can Co. in order to devote all his time to his automobile interests. He felt that it was unfair to remain an officer of the can company when he was able to give it so little of his attention.

Harbeck for some months past has been devoting himself to the affairs of the various John N. Willys enterprises in which he is a director and to the reorganization of the Maxwell and Chalmers companies. He is vice-chairman of the reorganization committee which is headed by Walter C. Chrysler, executive vice-president of the Willys companies.

It is expected the Maxwell-Chalmers consolidation plan, which has been approved by a large majority of the stockholders and creditors, will be declared operative about the middle of this month. No announcement will be made about the appointment of a new active management until that time. Both companies are in much better financial position than they were a few months ago.

Harbeck is essentially a financial man and because of this ability he was drafted with Chrysler by bank interests to save the Maxwell-Chalmers combination. Besides being a director of other Willys companies he is president of the Duesenberg Motors Corp.

N. A. C. C. STATISTICS SHOW ACHIEVEMENTS OF INDUSTRY IN 1920

Automobile statistics for 1920 as prepared by Alfred Reeves, general manager of the National Automobile Chamber of Commerce, show a total car registration of about 8,500,000, of which 900,000 are trucks. Production for the year is shown as 2,241,000, of which 335,000 are trucks. The combined wholesale value of the product reached $2,136,183,676. Exports for the year totaled $338,000,000. The figures are shown in the following tables:

Automobile Use

Automobiles registered in U. S. (approx.)	8,500,000
Passenger cars registered in U. S.	7,600,000
Motor trucks registered in U. S.	900,000
Cars and trucks owned by farmers	2,500,000
Per cent of registration in towns of 5000 population or less	55%
Per cent of registration in towns of 1000 population or less	33%
Per cent of 1920 output bought by agricultural districts	60%

Automobile's Part in Nation's Business

Amount of special taxes paid annually by industry to Federal Government	$257,000,000
Registration fees paid by car users	$81,000,000
Amount paid by industry to railroads for freight shipments on finished motor vehicles	$100,000,000

Production in 1920

Cars and trucks produced	2,241,000
Passenger cars produced	1,906,000
Motor trucks produced	335,000
Wholesale value of cars and trucks produced	$2,136,183,676
Wholesale value of passenger cars produced	$1,703,437,213
Wholesale value of motor trucks produced	$432,746,463

Automobile Exports in 1920

Value of motor vehicles and parts exported, including engines and tires	$338,000,000
Number of passenger automobiles exported	153,000
Increase in number of passenger cars exported	120%
Value of passenger cars exported	$155,000,000
Number of motor trucks exported	27,000
Increase in number of trucks exported	60%
Value of motor trucks exported	$45,000,000
Number of countries to which automobiles were exported during year	114

Dealers and Garages in United States

Passenger car dealers	36,210
Motor truck dealers	20,596
Garages	38,538
Repair shops	47,556

Army Truck Dumping Burdens Coast Market

LOS ANGELES, CALIF., Jan. 5—Pacific Coast motor truck dealers are alarmed over the prospective effects on their business of the importation of war trucks from Europe and their sale in this country and the suggestion of Congressman Anthony that the War Department be compelled to release between 30,000 and 40,000 trucks. Seventy-five trucks imported from Europe were unloaded here a few days ago. Similar cargoes are destined for San Francisco, Portland and Seattle.

These trucks have been brought here by the Slough Trading Co. of England and their local representative says the trucks originally were sold abroad by agents of the American government. The shipment received here is made up of Packards and Rikers, all practically new. The representative of the Slough company claims they have 4000 similar trucks to be marketed in this country, including Whites, Pierces and Peerlesses in addition to the Packards and Rikers.

He is seeking to dispose of the local shipment intact, but if he is unable to do so, he probably will auction them. He also has on hand large quantities of tires and tubes from the same sources. In view of the present market conditions, the arrival of these trucks from Europe and Anthony's proposal, the truck dealers are appealing to national associations and Congressional representatives for protection. They say the country might absorb 4000 trucks from Europe, but never 40,000 from the army.

Wilson Body Declares Big Stock Dividend

DETROIT, Jan. 6—The C. R. Wilson Body Co. has declared a stock dividend of 300 per cent, payable to all stockholders of record. Notwithstanding financial depression the company has had the biggest year in its history. There now is a steady increase in the number of orders for bodies.

REO RESUMES ON HALF TIME

LANSING, MICH., Jan. 6—The Reo Motor Car Co. has resumed operations after inventory. Its entire force of 5,400 men is working on half time.

Templar Stockholders Ask Stock Accounting

COLUMBUS, Jan. 3—Alleging that the W. O. Cooper Co. of Cleveland had made unjust profits "in disposing of stock in the Templar Motor Co. of Cleveland," J. W. Wilson, owner of 200 shares of common stock in the automobile company, and B. Pittman, owner of fifty shares of common stock, filed suit in the local courts asking for an accounting from the W. O. Cooper Co., and also for the rescinding of the contract between the two concerns over the disposition of Templar stock. The Cooper company, it is claimed, was formed for the sole purpose of selling Templar stock.

M. F. Bramley and W. O. Cooper, stockholders in both corporations, are named defendants and are charged with collusion in obtaining advantageous terms for the sale of stock. It is alleged that the Cooper company has received 25 per cent on the sale of stock, and in addition a bonus of $500,000 in Templar stock. Stock in the Templar Motor Co. unsold totals $8,500,000.

900 Tickets Issued for S. A. E. Dinner

Speakers to Discuss Economic Situation and Transportation —Review Road Tests

NEW YORK, Jan. 5—The annual dinner of the Society of Automotive Engineers which will be held next Thursday evening, promises to be one of the most successful in the history of the organization. More than 900 tickets already have been sold and it is expected the attendance will exceed 1200. C. F. Kettering will act as toastmaster. The speakers will be G. E. Roberts, vice-president of the National City Bank, who will discuss the economic situation and R. E. W. Cowie, vice-president of the American Railway Express Co., whose subject will be "Transportation."

One of the innovations in the program for the convention this year will be the discussions which will mark each of the various sessions. It is intended to devote half the time to formal papers and the other half to an informal discussion of them. No papers at all will be read at the chassis session Wednesday afternoon. It is expected a dozen of the leading engineers in the industry will express their opinion on this subject.

At the highway session Thursday afternoon A. T. Goldbeck will tell in detail of the highway research work done at the Government experimental station at Arlington. Approximately 20,000 tests of the effects on highways of various kinds of tires have been made and this work will be reviewed by Goldbeck.

The engineers are displaying much interest in the annual carnival which will be held Wednesday evening. The committee has not disclosed the program but has promised many surprises.

Transportation to New York and return may be secured by members at the rate of a fare and a half upon application to ticket agents.

Rubber Divisions to Meet

The various divisions and committees of the Rubber Association of America will meet the first four days of next week. The annual meeting of the association will be held Monday afternoon in the Astor Gallery at the Waldorf. The traffic committee and the executive industrial relations committee will hold sessions at the Yale Club, Monday morning, and the bicycle tire manufacturers committee at the same place Tuesday morning. The organization meeting of the board of directors to elect officers will be held at 4 p. m. Monday. A session of the executive committee of the tire manufacturers division, which will be held at the headquarters of the association Thursday morning, will be followed by a general meeting of the tire manufacturers division at the Yale Club in the afternoon. Luncheon will be served in connection with all the meetings.

So much interesting material has been made available for the aeronautic session of the Society of Automotive Engineers that two meetings will be held during the winter convention next week. The first will be Tuesday evening and the second Wednesday afternoon. Glenn L. Martin will preside at both.

Price Drops Thought Likely During Show

NEW YORK, Jan. 5—Keen interest is being displayed throughout the industry on the possibility that numerous price changes will be announced during the New York show next week. The general belief is that prices will be scaled down. This is based on the fact that labor costs are becoming materially less and that numerous parts makers are announcing cuts. Steel and other raw materials also are down.

One report is that reductions will be announced on several of the General Motors lines. The utmost reticence is maintained at General Motors headquarters here on this subject, but it is known that President Du Pont has been in conference with several of the large distributers to learn whether they believe lower prices would stimulate business. Cadillac and Oakland are mentioned most frequently in this connection.

When other companies were following the lead of Henry Ford last fall, General Motors stood pat and guaranteed its prices until the first of this year. If its schedules are lowered it is confidently expected all other companies which have not reduced already soon will do so.

DAVIS PRICES REDUCED

RICHMOND, IND., Jan. 3—George W. Davis Motor Car Co. has reduced prices on all models. The reductions range from $200 to $400 and bring the enclosed models under the $3,000 mark. The touring car has been reduced from $2,185 to $1,895, the special sport car and special roadster from $2,350 to $2,150, and the coupe and sedan from $3,185 to $2,795. These reductions have been made possible by a decrease in the cost of materials.

REYNOLDS CUTS PRICES

NEW YORK, Jan. 3—The Reynolds Machine Co., Massillon, O., manufacturers of automatic screw driving machinery for machine screws or wood screws, has sent letters to its customers announcing a substantial reduction in the price of its products.

The Electric Storage Battery Co. of Philadelphia has made a cut of 28 per cent in the price of Exide batteries of all sizes and types, effective Jan. 1.

RIVETT REDUCES PRICES

BOSTON, Jan. 4—A trade bulletin issued by the Rivett Lathe & Grinder Co. says "You can buy now Rivett machines at prices comparing favorably with those in effect in 1914." In a tabulation of new prices, compared with "peak prices" it is found that the price reductions range from 20 to 43 per cent.

METAL MARKETS

ONCE again the eyes of the metal market are riveted on the automotive industries, for there is no doubt that they are playing the part of the bellwether in the miniature buying movement that cast its shadows before in the closing days of the old year and which is slowly gaining momentum in the first week of the new year. So far only a small portion of this business is beyond the stage of preliminary negotiation, but the all-important fact that automotive buyers are once more in the market imparts to it an undertone of reassurance that is in sharp contrast with the doleful sentiment that had full sway a few weeks ago. To be sure, producers recognize that orders which a year ago would have been handed to them on a silver platter with the buyer's most devout wishes for speedy delivery will now cause an intensive scrimmage between sellers. The latter appear to be perfectly willing, however, to compete for business, being mighty grateful that some is to be had. This is the all-important fact. With the Ford Motor Company in the market for upward of 30,000,000 bolts, nuts and rivets; the General Motors Corporation reported to have placed an order for $1,000,000 worth of Oldsmobile bodies, and several passenger car builders inquiring for relatively good-sized tonnages of sheets, the steel industry is convinced that the corner has been turned. The automotive purchasing agent was the first out of the market, wherefore the prodigal's return is interpreted as a doubly happy omen.

Highly interesting, from a market point of view, are the brickbats which the copper industry is hurling at the automotive industries. A committee, known as the Copper and Brass Research Committee, has investigated the causes for the decline in copper consumption, and among these it has discovered that "in no one industry has public ignorance of the merits of copper and brass been more costly than in automobiles." "Since the first year of the war," says this report, "there has been a steady tendency toward iron products until the total amount of copper and brass now used in the average automobile is about 36 pounds. To this substitution in structural and working parts is attributed the tremendous increase in the automobile repair business in the last few years." With copper selling to-day at one-third of what it cost during the 1916 and 1917 flurries, it is quite possible that the automotive industries' interest in the metal may be revived to some extent, but the committee's findings ignore altogether the tremendous forward strides of alloy steels and heat treatment methods achieved since the war's outbreak.

Pig Iron—One report has it that the Ford Motor Company is now asking $33 base furnace, or $2 more than stated a few weeks ago. The market seems destined to remain in abeyance until consumers are convinced that they can not buy at $30, or sellers that $33 will not attract sufficient business.

Steel—Supplies of full finished body sheets in automotive builders' warehouses are reported to have dwindled and, aside from an inquiry for 1500 tons a month by a Detroit passenger car manufacturer, smaller tonnages are being sought by other interests. Prices generally are resting at the Corporation's levels.

Aluminum—Bargain lots of sundry imported and resale metal are still offered at 50 per cent below the sole producer's nominal contract price. At the first sign of demand the market is likely to stiffen considerably.

FINANCIAL NOTES

Chandler Motor Car Co. has fixed its net profits at about $5,000,000, or equivalent to $18 a share on the 280,000 share capital. This is following all write-offs, including a severe inventory shrinkage. In 1919 Chandler earned $26.91 a share before taxes on 210,000 shares Total production for 1920 is expected to reach 26,000, an increase of 8,000 over the previous year.

Gray & Davis, under the new American Bosch management, has been able to develop a modest earning power, which holds out the promise of substantial profits whenever business revives. From August to October, inclusive, net earnings totalled $36,000, after allowance of $61,000 for depreciation.

Miller Tire & Rubber Co. has declared a dividend on common stock, but has reduced it from 8 per cent to 4 per cent a year, or at the rate of 1 per cent a quarter. The reduction is made because officials deemed it wise at this time not to disburse any more funds than necessary.

Auto Sales Corp., reports net income of $118,035 for ten months ending Oct. 31 after deducting charges and taxes. This is equal to $2.22 a share on the $2,656,100 preferred stock of 50 par value. The balance sheet shows total assets of $7,575,414 and surplus of $381,729.

Paige-Detroit Motor Car Co. notified the Detroit stock exchange yesterday that the monthly dividend of 1 per cent had been passed. The company reduced the dividend from 2 to 1 per cent several months ago when the slump came in the automobile industry.

Parish & Bingham Corp. has passed its quarterly dividend due at this time owing to business curtailment in December. The inventory position of the company also influenced directors in their determination to pass dividends at this time.

Clayton & Lambert Mfg. Co. has declared a dividend of 2½ per cent on all stock record Dec. 16. This is the fourth cash dividend paid during 1920, making a distribution of 10 per cent cash and 25 per cent stock during the year.

Ohio Body & Blower Co. has passed its quarterly dividend due at this time. Curtailment of operations in the automotive industry so reduced operations in the body division that the dividend was not earned in the last quarter.

Biddle Motor Car Co. creditors will meet Jan. 11 at 82 Beaver Street, New York, to prove claims, appoint a trustee, examine the bankrupt and transact such other business as may come before the meeting.

Cleveland Tractor Co. directors have declared the first quarterly dividend at the annual rate of 7 per cent, payable Jan. 1. Previous dividends were at the rate of 6 per cent per annum.

Westcott Motor Car Co., Springfield, Ohio, has declared the usual 2 per cent quarterly dividend on preferred stock. The company is making preparations to resume full operations Feb. 1.

Pierce-Arrow Motor Car Co. directors will meet in February, not Jan. 11, as reported, to vote on the regular quarterly preferred dividend payable April 1.

Republic Motor Truck Co., Inc., has declared a quarterly dividend of $1.75 a share on preferred stock payable Jan. 1 to stockholders of Dec. 20.

Hupp Motor Car Corp., has declared a quarterly dividend of 2½ per cent on common stock, payable Feb. 1 to stockholders Jan. 15.

Jones Motor Car Co., Wichita, Kans., has been thrown into bankruptcy and M. E. Garrison has been appointed trustee.

Continental Motors Corp. closed its books Jan. 4 in preparation for the annual meeting of stockholders, Jan. 19.

Singer Motor Co., Mt. Vernon, N. Y., will be sold at auction Jan. 11, by order of Sidney S. Meyers, trustee.

Jordan Motor Car Co. paid its regular quarterly dividend Dec. 31.

G. M. C. Directorate Increased to 31

NEW YORK, Jan. 3—Directors of the General Motors Corp. at a meeting late last week omitted the stock dividend of one-fortieth of a share of common stock which has been paid quarterly since March of last year. The elimination of this portion of the customary dividend was no surprise, since there had been rumors recently that this was to be done. The directors declared the quarterly cash dividend of 25 cents a share on the common. The quarterly dividends of $1.50 a share on the preferred, $1.50 a share on the 6 per cent debentures and $1.75 a share on the 7 per cent debentures were also declared. All of the dividends are payable Feb. 1 to stockholders of record Jan. 10.

The Board of Directors was increased to thirty-one members by the election of K. W. Zimmerschied, C. F. Kettering and F. D. Brown. Both Brown and Zimmerschied were elected vice-presidents of the company, the first named to have charge of finances under the Chairman of the Finance Committee. L. R. Beardsley was elected an assistant secretary.

The position of General Motors at this time is said to be strong. It has on hand at this time less than 3500 complete vehicles, which is a remarkable showing in view of the fact that the total production for the year will approximate 400,000. Inventories of raw materials have been substantially reduced. Plants are being kept in readiness, however, to speed up production.

REPUBLIC RUBBER RESUMES

YOUNGSTOWN, OHIO, Jan. 3—Republic Rubber Corp. will resume operations Jan. 10, after being closed down since Dec. 23 for inventory and repairs. Pneumatic tire, tube and solid tire departments will begin with three eight-hour shifts on the 10th while the mechanical goods departments will resume Jan. 17. Orders received since the plant closed down are expected to keep it in operation for some time.

KELLY GETS TRUCK ORDERS

NEW YORK, Jan. 3—Directors of the Kelly-Springfield Truck Co. met here today but transacted only routine business. No decision was reached in regard to opening the factory at Springfield, O. A steadily increasing number of orders is being received but no more vehicles will be produced until those on hand are sold. The directors believe the truck market is improving and that the outlook is brighter than it has been for some time.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Jan. 6—Withdrawal last week by the Government of $36,000,000 of its funds, and the announcement of a further withdrawal of $45,000,000 to take place early this week, had no outward effect on the money market last week. These Government operations, together with the maturity this week of some $155,000,000 Treasury Certificates, had evidently been sufficiently anticipated. Call money was quoted without change all week at 7 per cent. Time money was scarce, with few transactions, and with nominal rates unchanged.

A decline of $16,354,000 in Federal Reserve notes was responsible, in the main, for the slightly improved reserve position of the New York Federal Reserve Bank last week. Total gold reserves declined $7,350,000, and bills on hand increased $10,105,000. Net deposits increased $5,129,000, and holdings of U. S. certificates of indebtedness declined $18,974,000. Total earning assets declined $8,869,000. The reserve position of the bank was better, for the first time during the year, than for the corresponding week of 1919.

The week-end statement of the Federal Reserve banks as a whole reflected an improved reserve position. The ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against net deposits, equalled the figure of Dec. 17, when it was 50.5 per cent. This ratio had been equalled only once before in the year, and exceeded only on Jan. 23, 1920. The week before, the ratio had been 49.8 per cent.

This improvement was chiefly a result of a decline in Federal Reserve notes in circulation of $60,245,000, accompanied by an increase in total gold reserves of $3,531,000. The total cash reserves increased $12,409,000. Bills discounted, secured by Government war obligations, declined $36,227,000, and total earning assets declined $18,012,000. Total net deposits, however, increased $54,842,000.

KARDELL PETITION FILED

ST. LOUIS, Dec. 30—An involuntary petition in bankruptcy was filed in the United States court yesterday against the Kardell Tractor & Truck Co. whose plant has been closed for two weeks. The company has built tractors but has never produced any trucks. The petitioning creditors are the Machine Products Co. of Cleveland with a claim of $15,659.74; Ruebelman-Lucas Hardware Co., $286.90, and William J. Kennedy Stationery Co., $5. The acts of bankruptcy alleged are the payment on Nov. 20 of $87.93 to Johnson Automobile Co. and on Nov. 24 of $64 in Liberty Bonds to the Liberty Bank. W. H. Kardell is president, and J. C. Kardell, vice president, of the tractor company which was incorporated in 1917. They also are president and vice-president of the Kardell Motor Car Co., but the two have no connection.

MEN OF THE INDUSTRY

L. B. McEwing, manager of the wholesale department of the Reo Chicago branch organization, has been promoted to the position of general sales manager with jurisdiction over both retail and wholesale departments as successor to N. O. Gilbert, former retail sales manager who has resigned. P. A. Collins until recently identified with the Reo factory engineering department has been named service manager of the Chicago branch.

J. C. Culbertson, president and general manager of the Wichita Motors Co. has been appointed a member of the committee which will work out the organization of the Foreign Trade Financing Corp., which will be formed with a capital of $100,000,000 to conduct foreign trade. He is associated with some of the leading financiers of the country. Wichita Motors now is selling its products in 83 foreign countries.

H. P. Meredith, formerly manager of the Curtis Airplane and Motor Corp., Garden City, L. I., has joined the Maxwell-Chalmers organization in Detroit as general works engineer in charge of all building design, construction changes, plant maintenance and power plant operation. His duties will cover the company's plants in Detroit, Dayton, New Castle, Ind., and in Canada.

Earl E. Harrington has assumed his duties as general superintendent of the Dellon Tire & Rubber Co., Baltimore. For the last five years he has been with the Goodyear Tire & Rubber Co. and his last service with it was in the technical service division where he worked on tire production and construction engineering problems.

H. A. Oswald has been made general manager and secretary-treasurer of the Hamilton Motors Co., Grand Haven, Mich. F. A. Inman has been named assistant to the general manager. E. A. Grabman is factory manager and fiscal agent representing the interest of Adolph Pricken, New York, the company's president.

I. L. Walker, manager of the engineering department of S. F. Bowser & Co., Inc., Ft. Wayne, Ind. has been appointed executive engineer. He has been connected with the company about twelve years. In his new position, he will have supervision over the company's dealings with insurance companies.

W. L. Carver has been made general manager and chief engineer of the Antigo Tractor Co., Antigo, Wis. B. W. Keene will be his assistant, and D. S. Stewart, designer of the tractor to be built by the company, has been elected a director and named consulting engineer.

Alfred Weiland has been appointed assistant to the president of the Pierce-Arrow Motor Car Co., acting for the president in matters relating to engineering. Weiland was formerly production engineer for the Wright-Martin Co., and later was with the Goethals Company.

William Elliott Phelps has been appointed general sales manager of the Haynes Automobile Co. He was formerly sales manager in the Chicago district for the Haynes company and previous to that had been general sales manager of the All American Truck Co.

Max B. Loomis has been made advertising manager of the Sparks-Withington Co. at Jackson. Mr. Loomis formerly was with the Reo organization and succeeds Major H. L. Hunt who returns to his newspaper work on the Jackson Evening News.

C. A. Bishop has been appointed western sales manager of the Hart-Parr Co. His headquarters will be at the factory, Charles City, Iowa. John P. Gregg has been named northwestern sales manager for the company.

Dan B. Hurlbut has been named factory representative of the Kroyer Motors Co., Stockton, Cal., manufacturers of the Wizard tractor. He was formerly connected with the International Harvester Co.

A. O. Williams is now secretary of the Automotive Association of Cleveland. Dale Brown has been acting secretary for the past year or so and Williams will now take up the active work.

E. S. Partridge, formerly Owen Magnetic and Liberty distributer in New York, has become New York branch manager for the American Motors Corp., manufacturers of the American 6.

Allen C. Chambers for three years sales manager of the Russel Motor Axle Co., tendered his resignation Jan. 1. He has announced no future connection.

Dr. F. G. Cottrell has resigned as Director of the United States Bureau of Mines. It has been arranged that H. Foster Bain of California shall succeed him.

Millard S. Binney, formerly advertising manager of the Traffic Motor Truck Co., has joined the Ross-Gould Co., advertising agency, St. Louis.

W. E. Nutting has been made general manager of the Detroit Motor Parts Co., to succeed R. B. Merrill, resigned.

Frank B. Willis has been appointed sales manager of the Duplex Truck Co., Lansing, Mich.

Moline Executives Earn Promotions

MOLINE, ILL., Jan. 3—H. B. Dinneen, general trade manager of the Moline Plow Co., has been placed in charge of the manufacture of farm implements. He went with the company a year ago from the John Deere plow works, of which he then was manager, and the capacity he has displayed in that brief period has brought his promotion. His preliminary experience has given him a thorough knowledge of the field requirements for Moline goods. His place as general trade manager will be taken by F. W. Edlin, who has established a wide reputation among men engaged in the distribution of farm implements.

Louis W. Fuller has been transferred from the drill works at St. Louis to become manager of the plow works in this city.

Liberty Takes Over Cameron Engine Sale

BRIDGEPORT, CONN., Jan. 3—The Cameron air-cooled engine, heretofore marketed by the Cameron Motors Corp., will hereafter be marketed as well as manufactured by the Liberty Mfg. Co., this city. Cameron will continue his identification with the Cameron engine as engineer in charge and also as a director.

A new plant completely equipped for and entirely devoted to engine production has just been completed by Liberty at Stratford, a suburb of Bridgeport. This plant will have a capacity of 30 complete engines per eight hour shift.

INDUSTRIAL NOTES

American Bosch Magneto Corp. expects to ship some 12,000 magnetos in the first two months of 1921. This compares with 40,000 in a single month in 1920. Beginning March 1 the company expects a decided improvement in business. The financial position of the company is good, its total quick assets being four times its liabilities. It is borrowing about $1,000,000.

S. F. Bowser & Co., Inc., Fort Wayne, Ind., did a $9,000,000 business in 1920 and is looking forward to increasing this to $12,000,000 in 1921. One per cent of the 1920 business has been set aside for distribution as a bonus to employees in July.

Cutler-Hammer Mfg. Co. has opened district offices in St. Louis under the management of Harold Phillips, formerly of the engineering department, Chicago.

Dayton Engineering Laboratories Co. has deferred the erection of its new $1,000,000 plant, owing to the present falling off in demand for automotive products.

McKone Tire & Rubber Co. will move its plant from Carrollton to Millersburg, Ohio, where the plant of the Foster Tire & Rubber Co. has been purchased.

Erie Tire Officials Held on Indictments

CLEVELAND, Jan. 4—The Erie county grand jury at Sandusky last week returned indictments for embezzlement against P. F. Wills and C. H. Roth, of Cleveland, both prominent in the affairs of the Erie Tire & Rubber Co.

Wills, president of the company, is charged in the indictment with obtaining $41,886.20 of the funds of the company, and Roth, a former treasurer, is charged with taking $63,593.82 for his personal use. While neither Wills or Roth have made a statement on the matter, it was learned that the indictments were the result of differences between the stockholders, and that both men accused claim to have defences. A stockholders' investigation was started last summer. Prominent in that probe were R. J. Bender, assistant auditor; William H. Briggs, purchasing agent; and H. H. Forest, office executive.

The grand jury charges that Wills took company funds by illegal operations through seventeen banks, and that Roth manipulated stock and other securities owned by the company. The corporation was capitalized some time ago for $4,000,000 and recently the capital was increased to $10,000,000, and extensive plant additions were made. The plant recently was closed for inventory.

OBENBERGER COMMITTEE NAMED

MILWAUKEE, Jan. 4—Roland LeBarre of the Interstate Iron & Steel Co. of Chicago has been appointed chairman of the creditors committee which is in charge of the affairs of the Obenberger Forge Co. An effort will be made to work out a plan under which all creditors will be paid in full and the company can be kept in operation. The assets exceed $1,000,000 and the liabilities are approximately $800,000.

Calendar

SHOWS

Jan. 8-15—New York. National Passenger Car Show, Grand Central Palace. Auspices of N.A.C.C.

Jan. 10-17—Portland, Ore., Annual Automobile Show, Automobile Dealers' Ass'n. Municipal Auditorium, M. O. Wilkins, Mgr.

Jan. 15-22—Philadelphia, Annual Automobile Show, Philadelphia Automobile Trade Ass'n.

Jan. 17-23—Milwaukee. Annual Automobile Show, Milwaukee Automotive Dealers' Ass'n.

Jan. 22-27—San Francisco, Second Annual Pacific Coast Automotive Equipment Exposition, Auditorium.

Jan. 22-29—Baltimore, Annual Automobile Show, Baltimore, Automobile Dealers' Ass'n, 5th Regiment Armory, J. C. O'Brien, Mgr.

Jan. 22-29—Cleveland, Annual Passenger Car Show. Cleveland Mfr's & Dealers' Ass'n, Wigmore Coliseum.

Jan. 22-29—Montreal, Annual Automobile Show, Montreal Automobile Trade Ass'n, Motordrome Bldg.

Jan. 29-Feb. 4 — Chicago, National Passenger Car Show, Coliseum, Auspices of N.A.C.C.

Feb. 5-12—Minneapolis, Annual Automobile Show, Minneapolis Automobile Trade Ass'n.

Feb. 7-12—Columbus, National Tractor Show, Columbus Tractor & Implement Club, Ohio State Fair Grounds.

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n. Armory, Arthur Fifoot, Mgr.

Feb. 13-19—Kansas City. Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—St. Louis, Annual Automobile Show, St. Louis Automobile M'f'rs & Dealers' Ass'n, Robt. E. Lee, Mgr.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, sec'y.

Feb. 21-26—Salt Lake City, Annual Automobile Show. Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Jan. 22-29 — Colombo, Ceylon Motor Show.

Feb. 7—Delhi, India, Delhi Motor Show.

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

CONVENTIONS

Jan. 11-12—S. A. E. Annual Meeting, New York City.

Feb. 2-4—Chicago, First Annual Meeting, Automotive Electric Service Assn. Hotel La Salle.

May 4-7 — Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

Van Sicklen to Sell New Newark Factory

NEWARK, N. J., Jan. 4—Due to the change in the industrial situation, the Van Sicklen Co., a Willys subsidiary, has determined to abandon its plan to build speedometers here in the new plant just completed at 76-84 Warren Street, and will instead continue the manufacture at the present plant at Elgin, Ill.

In keeping with this decision the Newark plant has been offered for sale and negotiations looking to this end are expected to be completed within a few days. The sales price has been fixed at $850,000. C. W. Curtiss, who resigned as general manager of the Splitdorf company to accept the general managership of the Van Sicklen company, will represent the latter in the sale of the building and will then sever his connections. His plans for the future are not announced.

The building is a modern eight-story structure, with a sprinkler system throughout, containing 186,000 sq. ft. of floor space. Much of the machinery for the new building had been contracted for and some of it had been set up. With the change in plans this machinery will be sold for the most part and some of it transferred to the Elgin plant where it will be employed.

N. A. C. C. SURVEYS FARM TRUCKS

NEW YORK, Jan. 4—The motor truck committee of the National Automobile Chamber of Commerce, with the co-operation of departments of agriculture in all States, will make a survey of the use of motor vehicles on farms throughout the country. A questionnaire similar to the one mailed in the recent New York State survey will be used. Seven questions are outlined which aim to discover the needs of individual communities and to ascertain the value of co-operative motor truck lines in specific localities.

Goethals to Advise on Ohio Highways

COLUMBUS, Jan. 3—Governor-elect Harry L. Davis announces that he has wired Major General George W. Goethals, builder of the Panama Canal, and former Quartermaster General of the Army, asking for a conference in Columbus immediately after his inauguration early in January for the purpose of getting advice on the reorganization of the Ohio Highway Department. The reorganization of the Ohio Highway Department has been given a great deal of attention by the incoming governor and which he promised to accomplish during his campaign speeches.

"I am looking for the biggest man I can find to aid me in the reorganization of the Ohio Highway Department, which spends millions of dollars each year on roads," said the Governor-elect. General Goethals will be asked to spend as much time as possible in Ohio while the reorganization is taking place.

NEW CASTLE RUBBER SUED

NEW CASTLE, PA., Jan. 3—An involuntary petition in bankruptcy has been filed by Chicago creditors against the New Castle Rubber Co. Assets are estimated at $1,500,000 and liabilities at $4,500,000.

Tilden to Direct Highway Education

NEW YORK, Jan. 3—C. T. Tilden, professor of engineering mechanics at Yale University, and one of the best known engineering educators in the United States, has been named director of the work of the Highway and Highway Transport Education Committee with headquarters at Washington. He will take up his duties at once and will formulate a comprehensive program for courses in highway and highway transport education.

Professor Tilden was called to Yale from Johns Hopkins a year ago to undertake the reorganization of the engineering courses at Yale. The importance of his present task may be gaged from the fact that the Yale authorities were ready to grant him a year's leave of absence in order to lay out the program of work for the new organization.

Professor Tilden is the author of a number of technical and historical papers on engineering, one of the most interesting, perhaps, being that on "Kinetic Effects of Crowds." He has also held positions as consulting engineer, being attached to the staff of the Bureau of Public Roads and the Emergency Fleet Corp. in that capacity.

The Highway and Highway Transport Education Committee is the outgrowth of a conference on these subjects held in Washington last May.

U. S. LIGHT CUTS BATTERY

NIAGARA FALLS, N. Y., Jan. 3—United States Light & Heat Corp. has reduced prices on its batteries from 20 to 25 per cent, effective at once.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, JANUARY 13, 1921 No. 2

Novelties Not Abundant at New York Show

Effect of recent depression not yet reflected in passenger car design. Most models shown are similar to those exhibited last year, but brighter colors add attractiveness. Some new chassis and engines have features and refinements which are described here.

ANY results that the motor car depression of the last seven months may eventually have on vehicle design has not yet become apparent in the exhibit of the eighty-nine makes of vehicles at the twenty-first national show of the National Automobile Chamber of Commerce now running for the week in Grand Central Palace. Engineering departments may be working overtime in factories on designs that admit of more economical manufacturing and that will give improved performance due to light weight, better use of fuel, etc., but these are not at the show, excepting in a few instances where changes in manufacturing programs were decided upon a year ago and the new products are not a direct result of the trend of events in the last few months.

As a show it parallels rather closely in character and quality that of a year ago, there being 307 exhibitors a year ago and the same number this week. It is not the biggest show in history as 1913 recorded 424 exhibitors. It was not to be expected that many new designs would be on hand as the unsatisfied demand that continued up to last June was not conducive to the production of new designs.

The show carries external evidences of many concerns adding merchandising features not so prominent in former years, particularly with models that are not in greatest demand. On touring cars and roadsters the show contains more specially painted jobs. Glass wings on windshields are added merchandising talks. On most of the fifty-six cars fitted with disk wheels the equipment is a sales argument rather than an indication of stock equipment. Disk wheels have not yet reached this status in stock equipment.

On the other hand the exhibit of but thirty-eight polished chassis falls behind the record of former years, yet the attention that these constantly receive must be accepted as an indication of the interest if not the sales value of such an exhibit. Relatively new chassis, such as LaFayette, Lincoln and Pierce-Arrow are magnetic centers. The sales value of a good chassis cannot be overlooked and it might be injected as a show criticism that manufacturers could to advantage continue the chassis exhibit and add to the merchandising value of the show space. The show should be used as one factor in bringing about the disintegration of a buyers' strike. Every merchandising feature needs to be used to the maximum. The Marmon exhibit of miniatures made to one-quarter size is one example of a good merchandising thought.

As indicating a trend of design the fact that the number of four-cylinder cars has been increased by fifteen, and six-cylinders reduced by ten, suggests the increasing utility aspect of the industry. There are no so-called engineering avalanches at the show, no

influx of fours, sixes, eights or twelves. There is no trend toward a greater use of multi-cylinder jobs, rather a stationary situation excepting for a slight movement toward fours. The question of cylinders is more an engineering one rather than a merchandising one. The time when a maker changed from a four to a six, or from a six to an eight to get into a certain market has little echo in the present show.

The criticism that reached America from the recent Olympia show in London to the effect that our touring cars were sorely criticized both from style and comfort viewpoints might be taken to heart to advantage. Too many cooks spoil the broth, and frequently factory heads quite ignorant of the fundamentals of body design have a major say in it. The fact that the body design does not make a good engine worse or a poor engine better permits of someone dictating a design who would not dare to interfere in the design of an engine, or transmission system. Fools step in where angels fear to tread. It is not surprising that there are body designs that are not a credit to the manufacturer. There is indication of a trend away from the present straight edge body style to the rounded edge. The straight edge job calls for more art in handling than the rounded edge. It is easier to work with curves than straight lines. The return to the curved lines is being forced on body engineers because the straight edge job has been so poorly done in too many cases. A good body engineer can accomplish a most satisfactory result with either, but the amateur cannot.

There can be no doubt but that the demands of production in the last five years carried a penalty of sombre colors. The present buyers' market is bringing out the nickeled radiator, which not only adds distinction but is certain to receive more attention. There are more of these in the show than there has been for many years. They are meeting with a favorable response.

The Combination Body

The combination summer and winter body is not a strong factor, the exhibit of eighty different models of sedans indicating the necessary demand for these and the exhibit of not more than half a dozen so-called all-year bodies indicating how unsettled is that design. The so-called California top with its permanent overhead portion and removable tops for the doors and removable sides is not in great numbers, the added cost of approximately $500 involving a fairly high sales resistance. There is an unmistakable feeling that there should be a lower price for an all-year car.

With roadsters a commendable advance is dropping the folding rear seat, which so often was more of a talking point than a feasible design, and making worth while baggage carrying compartments in the rear. There are a few roadsters with ample space for suit cases, coats, golf clubs and robes. There is a broader field for the roadster if it is made more complete in these regards.

A point to be guarded against in winter tops as well as closed designs is the blind spot at the end of the windshield. The glass windshield wings on a few cars have an extra amount of attaching parts which constitute a blind spot. One or two examples of winter tops have front side curtains that are bad offenders and their use certainly courts accidents in city driving in stormy weather.

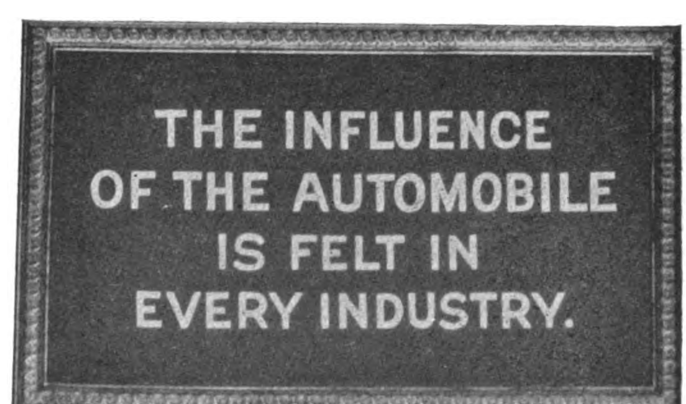
The road wheel is still an unsettled feature in the industry, not so much whether artillery, wire or disk types dominate, but rather the question of peripheral weight. Europe never has agreed with us in the heavy demountable rim and the handicap it places not only on the acceleration but deceleration. The demountable rim was a first essential until the cord tire has to such an extent eliminated tire changes. The demountable wheel has reduced peripheral weight, but it has largely been confined to wire and disk types. Not a few engineers are seriously considering whether or not the penalty of the demountable rim is a too heavy one to-day. In appearance the demountable rim never has been attractive and some of the wheels at the show are really eyesores. Disk wheels are still too expensive.

Leaving off the runningboard and using front and rear steps is more general than heretofore, but this again is to be interpreted as an easy step to a merchandising talk. Some of the steps are veritable wash basins and look the part, while others are fashioned more after carriage art, and unquestionably add a note of smartness. There is a possible danger factor where the steps are too large and have suspicious looking sharp edges that might injure a passing pedestrian.

The Salesmanship

Coming, as the show does, at a time when every sales inquiry should be made the best of, one criticism must be made, namely, the regrettable lack of full information on the part of the salesman in the exhibit booths. These salesmen should know the meritorious parts of the car, but too often they do not. Too often they cannot point out the good production features. Too often they are ignorant of the good maintenance points. Wheelbase, tire sizes, number of cylinders and number of speeds are not enough. The average show visitor who is looking over the cars with buying in mind should be given all the information desired.

The psychology of the salesman in the exhibit booth is too frequently almost negative. In a few stands the apparent rôle was to approach everybody before they reached the car or chassis and ask what point of the car they were interested in. That is not good psychology, as many were observed who wanted to shop around and it was quickly noted that too insistent attention of the salesman was resented. The analytical salesman does not thrust himself on the prospect but rather studies him, notes what part of the car or chassis he is interested in and then studies the exact moment when his assistance is needed and is ready at that second. The salesman should realize that the show visitor who pays his 75 cents for the privilege of attending the show to see the cars has a certain privilege in each exhibit space. The spaces are the display windows of the show. Give the visitor his free right to use them. The old question of "Are you interested in cars?" is not heard, but there is need for better show salesmanship, for studying the visitor and endeavoring to assist him and not interfering with him.



One of the slogans at the New York show

Engines Exhibited at New York Show

By P. M. Heldt

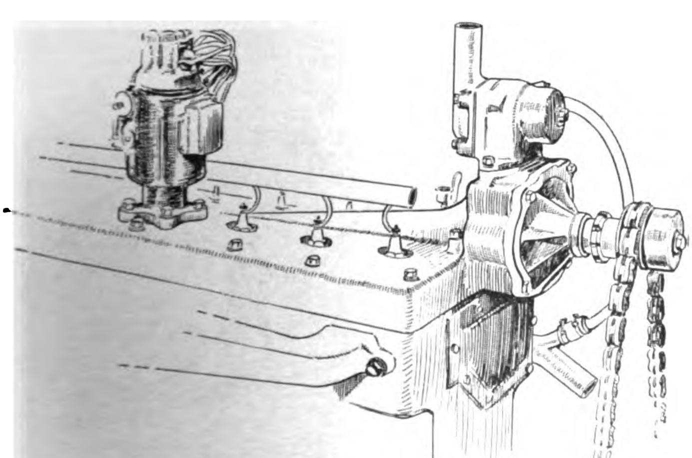
CONTRARY to expectation there are no surprises at the automobile show this year; that is, entirely new models of which announcement was withheld until the show opening. Of cars which are exhibited this year for the first time there is a fair number. There are first of all the Packard single six, already fully described in these columns, and the new Pierce-Arrow car which will be the only passenger chassis model of the Pierce-Arrow company the coming year. There are two newcomers in the eight-cylinder class, the Lafayette and Lincoln. The Fergus, while not an entirely new design, shows many changes as compared with last year's model. In the medium priced class there is, first of all, the new Lexington model equipped with the new Ansted engine, which was specially designed for operation at high speed and which embodies a new idea in valve actuating mechanism. There is also a new Oldsmobile, a four, but its engine presents such striking family resemblance to certain other products of the General Motors Corp. that to one in search of novelties in engine and accessories the design is somewhat disappointing.

Leaving the show proper for a few moments and visiting some of the nearby hotels whose lobbies have been converted into show rooms for the week, we find some of the most striking novelties. This is not at all surprising when it is considered that at the show members of the N. A. C. C. receive first consideration and applicants for space are accommodated in the order of their last year's production; hence the oldest and the largest manufacturers are represented at the Palace while the smaller and newer concerns have space at the hotels, and as conservatism generally grows with age and volume of production it is only natural that the most radical models are seen at the hotels. This applies to such cars as the Ace, the Parenti and the German Sauer. Then there is another class of new cars at the hotels, designed along conservative yet up-to-date lines, such as the Navarre and Ferris, which will probably be built on a moderate scale mainly for use as closed cars.

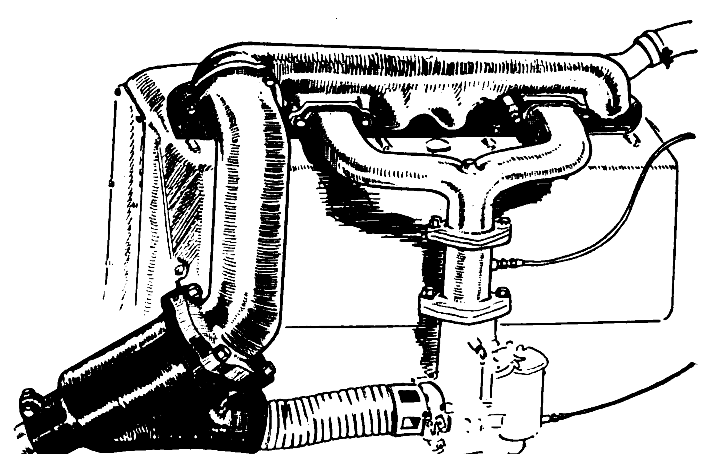
After this brief outline of the outstanding novelties, we may pass to a consideration of engineering features in connection with engines and engine appurtenances exhibited by cars at the show and especially those shown in chassis form. It may be mentioned that some of the leading firms, notably the Hudson and Marmon companies, do not exhibit a show chassis this year. Whether the reason is a desire to save the cost of a sectioned and highly polished show chassis—which is by no means small—or whether it is believed that the available space can be utilized to better advantage by exhibiting a full line of the models offered, is a question, but it is most likely that the last mentioned reason is the real one, for to judge by rumors of the cost of the models exhibited at the Marmon stand economy was not an important consideration in the preparation of that exhibit.

In its new single six the Packard Motor Car Co. has struck a new note with respect to location of engine accessories. With the constant increase in the number of these accessories their arrangement has become somewhat of a problem. When placed on the sides of the engine between the crankcase and the frame they not only interfere with access to the engine but often are hard to get at themselves. In the new Packard the ignition unit is placed centrally on top of the engine and the pump, which is of the water circulation type, together with the fan and thermostat form a unit also located high up in front, so that there are few auxiliaries on the sides of the engine. The control rods from the ignition unit and carbureter are, moreover, very neatly arranged, running substantially parallel with the engine axis, which makes them unobtrusive and gives a clean cut engine layout.

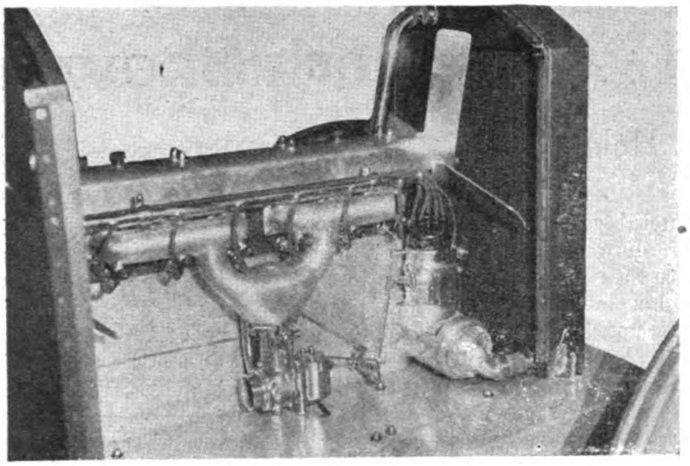
In respect to control rod connections many designers still have much to learn. In a great many cars either the carbureter or the ignition unit is located on the opposite side of the engine from the steering gear, and this requires running the control linkage around—or through—the engine. Now that an interconnection between the throttle valve and the pressure relief valve on the lubricating system is provided on many cars, this linkage has become even more complicated than formerly. On one car no less than eleven ball joints were counted, and as these were of the type in which the socket is spun over, which usually gets very loose after two or three years' service, such cars naturally age very rapidly. Of course, it is not a great expense for the owner to put in a complete new set of these ball and socket joints, but the average owner will not take the trouble, though the rattle will annoy him.



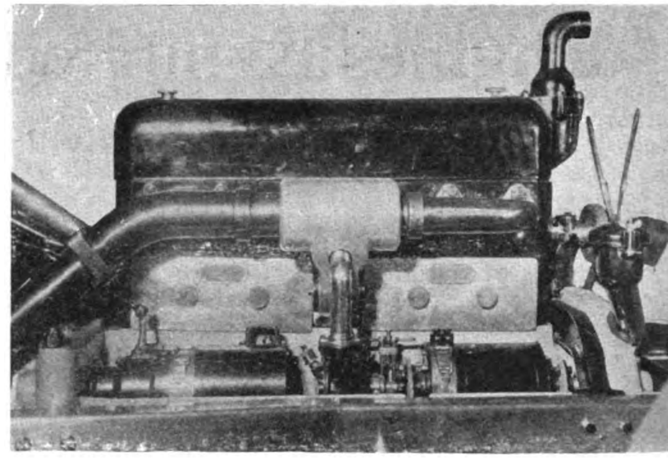
Packard places accessories above rather than at the sides of the engine



On the Roamer the exhaust pipe runs conveniently near the carbureter for a hot-air connection



Left-hand side of Fergus engine



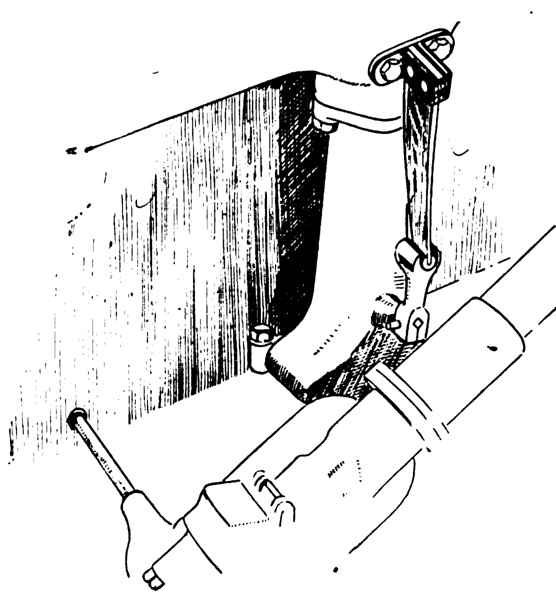
Exhaust side of Pierce-Arrow engine

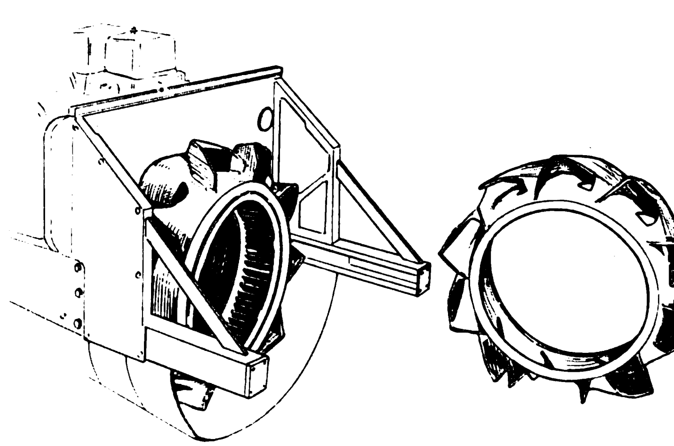
Where connections have to be made from the steering gear on one side to auxiliaries on the opposite side of the engine it is often a good plan to carry a control shaft right through the engine, either through the crankcase or the cylinder block. Such an arrangement is now found on quite a number of cars, notably the Templar. Whatever exposed linkages there are should be arranged in a neat manner, the individual links preferably in the three main planes. The Italians are pastmasters in the art of neat design, but Mr. Ferguson in the Fergus car has shown that the Latin race has no monopoly on the ability to produce simple looking and attractive layouts.

Whenever there appears some simple improvement whose advantages are obvious, it is remarkable how quickly it is taken up by designers generally. It is now hardly a year ago that attention was first called to the practice of providing oil cocks with extension handles so that they can be reached without getting down under the chassis, yet at the show these extension handles are found on many cars. There seems to be a tendency to discard the float type of oil gage. In the new Pierce-Arrow, for instance, the oil sump is provided with two try cocks whose stems extend up through the continuous web of the crankcase into a position where they can be easily reached. As there is no sod pan, the cocks can be easily seen, and as they extend straight out from the side of the oil pan they can be easily cleaned if they become clogged with dirt. No doubt this method of determining the oil level in the case, while ordinarily not as exact as the float indicator, is on the whole more reliable. It was noticed that the bayonet type of oil gage, which heretofore has been used almost exclusively on truck engines, is rapidly coming into use also on passenger car engines, particularly those of the less expensive type.

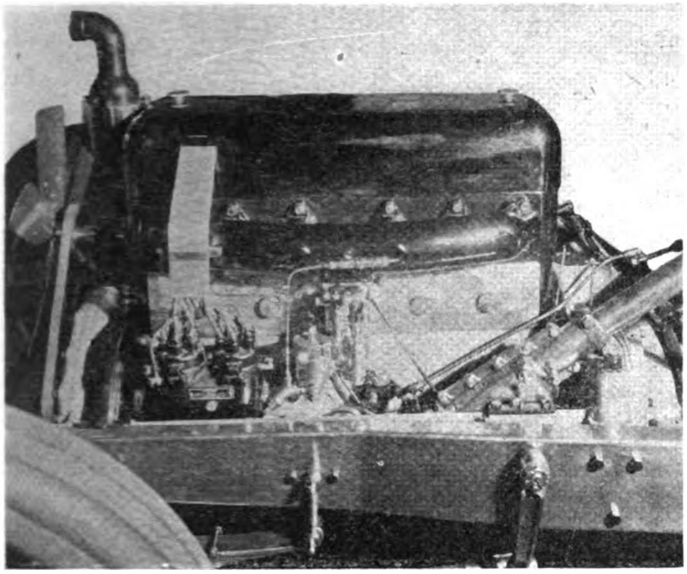
Valve enclosure came first in connection with L-head engines. Several years later makers of T-head engines found that in order to hold their own they also would have to enclose the valves, though, since valve chambers had to be provided on both sides of the engine, this involved a greater increase in weight than in the L-head type. The valve-in-head type with tappet rods extending up one side of the engine resisted longest the general tendency to enclose all working parts, but finally the hour of the exposed long tappet rod has struck too. In certain engines, such as the Weidely, the tappet rods extend up through a chamber whose walls are cast integral with the cylinder block which gives generally the neatest construction, but most designers cannot convince themselves that the very considerable increase in weight necessitated by this construction is warranted. In the Dorris the rods are enclosed individually in tubes extending between the crankcase and an overhanging portion of the head. This, of course, hides the moving parts, but it does not give that simplicity of outward form which is the aim of many designers. On the Buick and several other cars sheet metal covers are secured over the side of the engine on which the tappet rods are located. In the Buick the cylinder block is cast with offsets or steps along the vertical center line at both ends, against which the metal cover fits.

The bell housing construction is constantly coming into

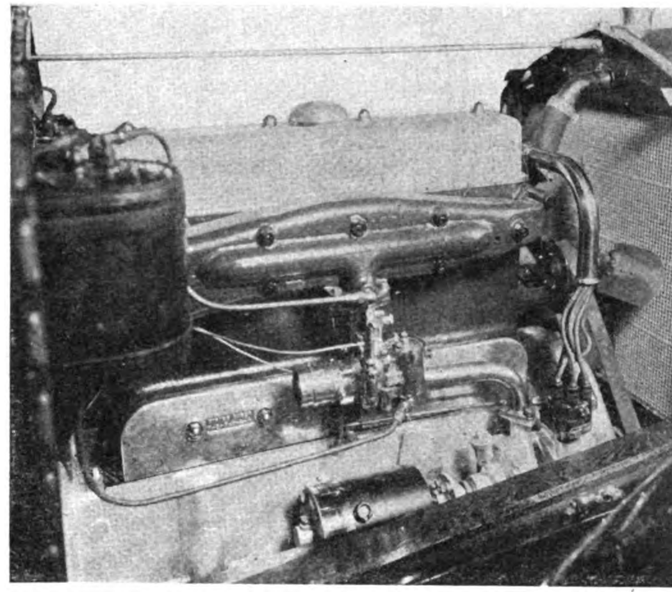




To the left—Thermostat on Fergus car for controlling exhaust heat. Above—Aeroduct casting over Sirocco fan on Holmes engine



Inlet side of Pierce-Arrow engine

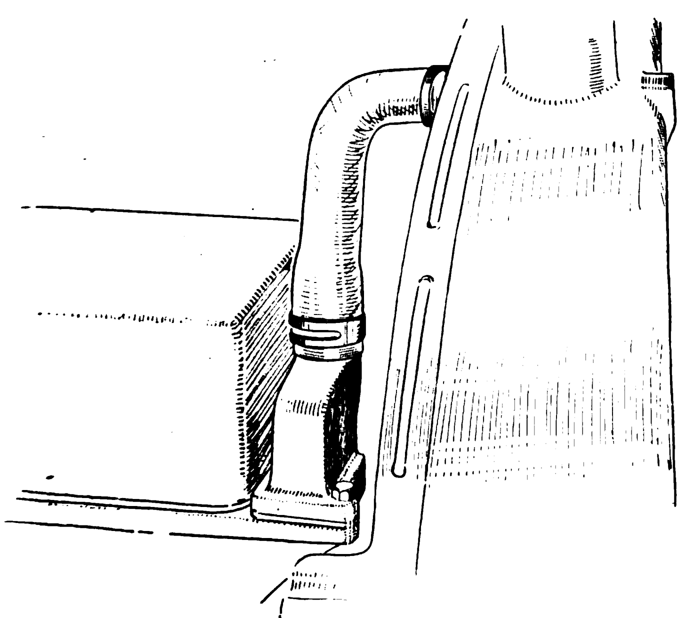


Valve side of Northway engine

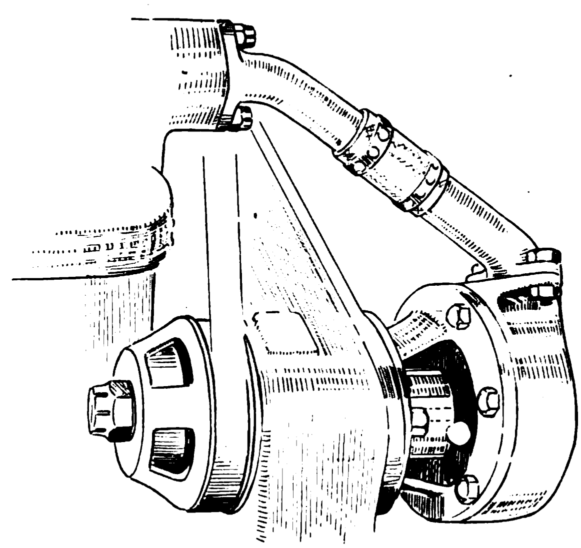
more general use, among those who have adopted it recently being the Pierce-Arrow Motor Car Co. Although the Pierce retains the separate transmission amidships, it now has an enclosed flywheel and clutch, and this has eliminated the characteristic Pierce engine suspension by means of two drop forged carriers. At the front the drop forged carrier is retained, but at the rear integral arms extend from the bell housing and rest upon lugs riveted to the frame, the holding down bolts passing through the arms and lugs being provided with coiled springs under their nuts to provide flexibility.

In reports of the European shows this year attention was called to the growing popularity of continuous webs between the engine crankcase and the chassis frame, and the same tendency is observable here. The sheet metal underpan is always more or less of a nuisance, because of the amount of dirt it will collect and because in some cases when parts or tools drop into it they are hard to get out again. Besides, it slightly reduces the road clearance and without it the engine can be set correspondingly lower, which makes for a lower center of gravity. Practically all of the new high grade cars with vertical engines have continuous webs, and where they are not cast integral with the crankcase, filler plates are sometimes bolted between the crankcase and the frame, as in the Fergus.

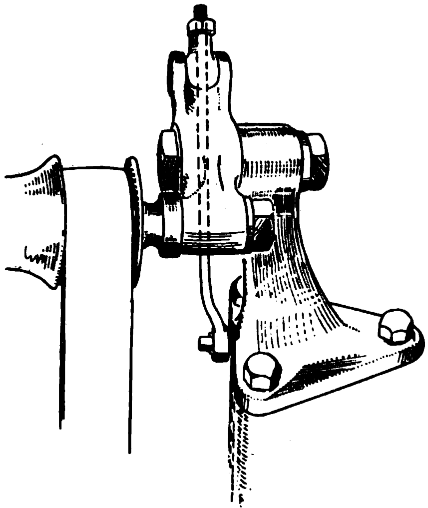
When an overhead valve engine has a cover over the valves, something of a problem is presented by the water outlet from the engine jacket. As such covers have been applied only during the last year or two the problem is a relatively new one, and this is reflected by the variety of solutions worked out. In the Stephens six-cylinder engine, which is related to the Moline tractor engine, the valve cover is jacketed and the outlet header or manifold is cast integral with the cover. One explanation of this design is undoubtedly that in a tractor engine, which works constantly very close to full capacity, the valves and their adjacent parts get very hot, and jacketing the cover undoubtedly tends to keep them cool. In the Buick there are two small indentations of the cover on one side where the water return manifold bolts to the cylinder head. In the



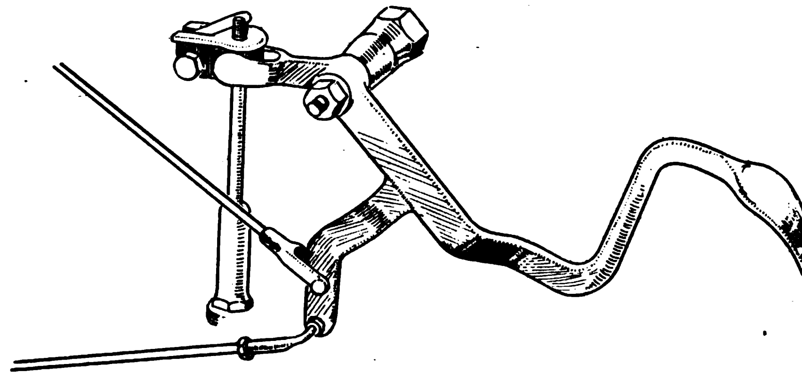
On the National overhead valve engine the water outlet from the head is through a forward extension of the head casting



On the Du Pont the fan pulley is behind the gear case and the water pump in front of the casing on the same shaft



Positive fan adjustment on Templar

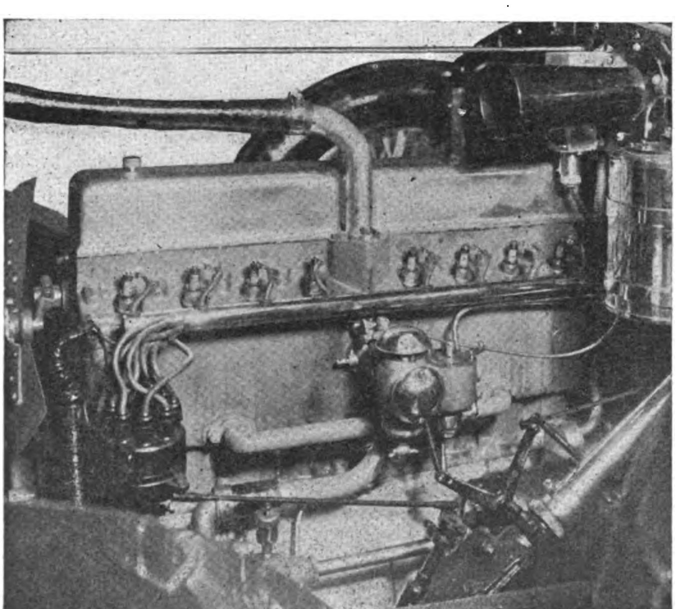


Stearns accelerator pedal has several crooks, but its connections are simple

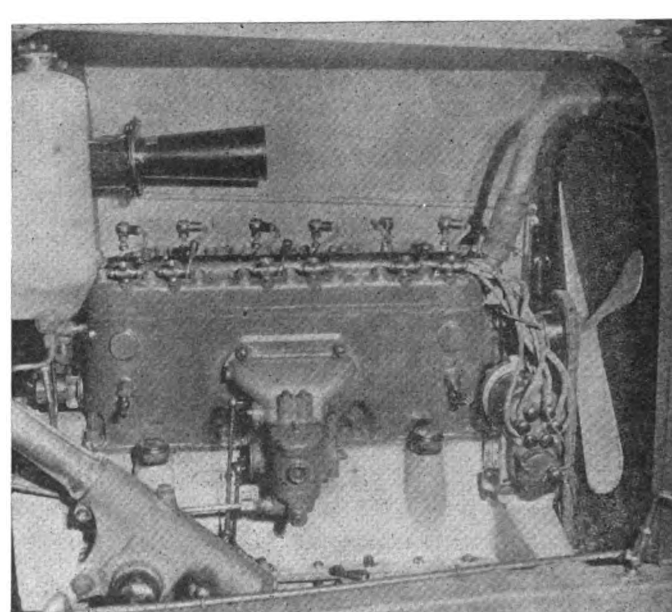
Scripps-Booth the outlet from the cylinder head is under the valve cover and the water is led through a pipe fitting secured into the side of the cover at the middle of its length. On the National and several other engines the head casting is slightly extended at the front, beyond the reach of the valve cover, and the water return pipe bolts to this extension. This latter solution is undoubtedly the simplest and neatest, and the only reason for some of the others probably is that the cylinder head castings were already in existence when the problem of covering the valves arose.

While on the subject of water connections mention may be made of some expedients resorted to in order to get uniform distribution of flow and consequently uniform cooling action. In most cases the pump is mounted near the front of the engine, which makes it most convenient to have the water inlet near the front, and the outlet from the cylinder jacket to the radiator also comes most naturally either at the middle of the head or some point forward thereof. Consequently there is danger of sluggish circulation in the rear jackets, and as it is the hottest cylinder that causes trouble from knocking and faulty lubrication, it is important to take precautions against this eventuality. In the Du Pont car, in which the pump is located in front of the engine and driven from a forward extension of the accessories shaft, the water inlet connection to the cylinder block is made at the front end but a pipe extends through the jacket to the rear, and as the outlet is also at the front the water is compelled to flow through the entire length of the jacket. The somewhat similar arrangement on the aluminum engine of the Premier car is well known and is shown to good advantage in a cut-away model at the Grand Central Palace. On the engine of the six-cylinder Kissel car, on the other hand, where the pump is located at the side of the engine forward, the inlet pipe is run along the side of the cylinder block and the water enters the jacket at the rear.

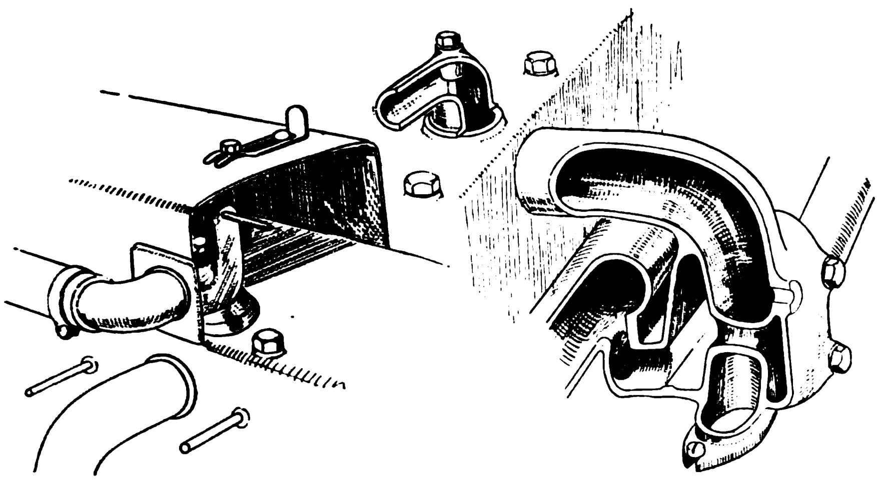
Where the inlet manifolds are jacketed it makes for simplicity and neatness if the inlet to and outlet from the jacket are through ports alongside of the main inlet ports of the manifold. In the new Pierce-Arrow, water from the engine cooling system enters the jacket in this way, and in the Lafayette, exhaust gas. In connection with manifolds it seems to be a good plan to hold them in place by means of studs whose nuts are outside the plane of the manifolds, as such nuts can be screwed in place and removed much



Carbureter side of engine on Kenworthy car



Carbureter side of engine on Fiat car



On the left is sketched the water outlet from the cylinder head of the Scripps-Booth and on the right the sectional inlet and exhaust manifolds of the Oakland

more conveniently than nuts passing through lugs or ears cast on the manifold and lying close up against the cylinder block. Moreover, if the nuts press on clamping pieces or bridges between sections of the inlet and exhaust manifolds, as in the Scripps-Booth (Northway engine), they will not get so hot and are not so apt to rust tight as if bearing directly against a part of the manifold. On the Fergus engine the exhaust manifold is held in place by five studs passing through cast-on bosses the whole depth of the manifold, thus bringing the nuts into accessible positions.

Although the hot spot and exhaust jacketed manifolds are constantly gaining in favor there are still many engines which merely preheat the air before it enters the carbureter and do not apply any exhaust heat to the mixture after it is formed. In some designs the flexible pipe connection between the hot air stove on one side and the carbureter on the other side is inordinately conspicuous. In the new Pierce the hot air is carried right through the cylinder block between cylinders Nos. 3 and 4, and in the Roamer, using the Duesenberg engine, the connection is short and direct, as shown by the sketch herewith, the exhaust and inlet being on the same side of the engine as the carbureter.

At each show in recent years—and the present one is no exception—there have been exhibitors who in the course of the year had changed from splash to force feed lubrication. With this change often goes the adoption of oil pressure control in proportion to throttle opening. This method of lubrication control is in use on the Chalmers and Liberty, the Kissel and Stearns among others. On the Stearns car the linkage from the accelerator-pedal and throttle lever rod to the throttle valve and oil pressure relief valve is particularly neat, and is sketched herewith.

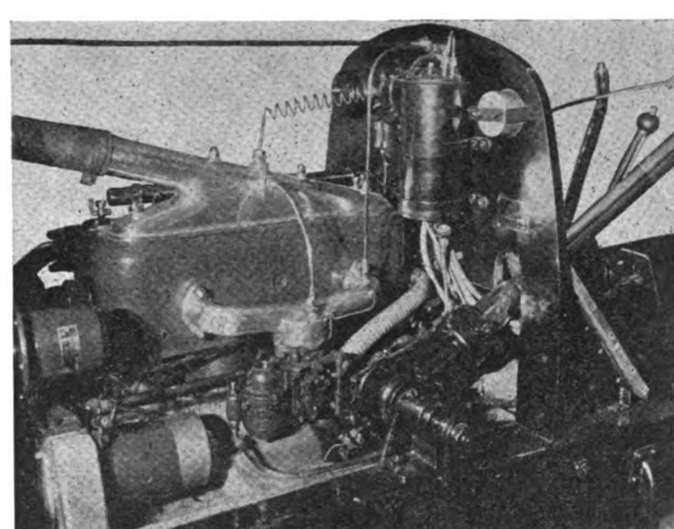
Restriction of the outlet passage from the engine space has long been a cause of poor cooling of engines, or, perhaps, it would be more correct to say that this was formerly a frequent cause of poor cooling, because the fault has often been pointed out and has been remedied on most water cooled cars. One of the improvements in the Holmes air cooled car aims at eliminating this fault. This car has a centrifugal type of fan, forming the flywheel, and as the outlet from this fan is in a radial direction and the space between it and the mud pan and other parts of the enclosure is restricted the circulation of the air has been greatly hampered. By installing what is called an aeroduct (see sketch) the rate of air circulation at any given engine speed is said to have been practically doubled. This device consists merely of an aluminum casting surrounding the fan flywheel on its circumference, in which are formed a series of air passages which gradually change the direction of the air from perpendicular to parallel the car axis. Holmes has also done away with the rather intricate valve mechanism formerly employed and now uses a plain tappet and rocker motion.

It was noticed that on the high grade cars the use of steel pressings for the oil pan, gear cover and such parts is scrupulously avoided. From a strictly practical standpoint pressed steel would seem to be as good as aluminum, as the constant pressure of oil will keep it from rusting, and if there is any difference in weight in favor of aluminum it must be very slight. Aluminum, however, looks better.

A feature of interest from a maintenance standpoint was observed on the Mitchell six-cylinder engine, in the form of an eye bolt in the cylinder head casting by which it can be easily removed when necessary. Although this feature is not new with the Mitchell, it does not seem to have been copied so far. The nearest approach to it in other engines noticed by the writer is in the form of overhanging lugs at the ends of the head casting which afford a grip when the head is to be removed.

The Oldsmobile eight has the generator mounted centrally in front and driven by belt, the fan being mounted on an extension of the armature shaft. This is similar to the construction used on the Nash. Belt drive of the generator was also noticed on one other car where the fan was not combined with the generator. While there is some objection to a non-positive drive of the generator it must be remembered that the power consumption of the latter is much less than that of the average fan. The average generator delivers not over 20 amperes at about 7 volts, which is equal to 140 watts, and at 50 per cent generator efficiency the power required to drive the generator is only slightly more than one-third of a horsepower.

Quite a few designers now place the driving pulley for the fan belt on the accessories drive shaft *behind* the gear housing. This has the advantage that it eliminates one shaft outlet from the gear housing and one chance for oil leakage. Thermostats are finding additional applications on automobile engines. Thus on the Fergus engine there are two serving novel purposes. One is in the form of an aluminum rod inside the hollow overhead camshaft, which,



Left-hand side of engine on new Du Pont car

as it expands from the growing heat of the engine, engages the friction clutch by which the fan is driven from the camshaft. When the engine is cold the fan does not rotate, or at least not at any speed. The other thermostat, which is of the compound metal strip type, extends down the side of the exhaust pipe and controls the opening of the exhaust bypass through the inlet manifold jacket.

In a class by itself is the small Fiat car which has an engine of probably not much over $2\frac{1}{2}$ in. bore. This, of course, is a car designed for economical operation, and as low first cost should go with low running expense, some of the features found in the larger Fiats have been eliminated. Thus the fuel, instead of being carried in a rear tank from which there is pressure feed to the carbureter, is contained in a flat tank on the forward side of the dash. With the low consumption of these small engined cars a sufficient supply can be carried in this way, especially since the dashboard and the radiator opposite it are very large as compared with the diminutive engine.

Fan tension adjusting means are sometimes a weak point. If the cranked support is used and adjustment made by swinging the crank around its stud and then clamping it on same, the tension often loosens quickly owing to irregularities, such as a heavy lap joint, in the belt. In the Templar, although the fan is supported by a crank, adjustment is made by a positive device in the form of a pullrod with nut, as shown by the accompanying sketch.

On the Navarre, which is a new car built in Springfield, Mass., an outside water inlet connection to the cylinder is eliminated by bolting the pump up against a water passage in the crankcase which communicates with a vertical passage through the cylinder block. This vertical water passage is at the middle of the length of the engine.

Refinements in Chassis Construction

By J. Edward Schipper

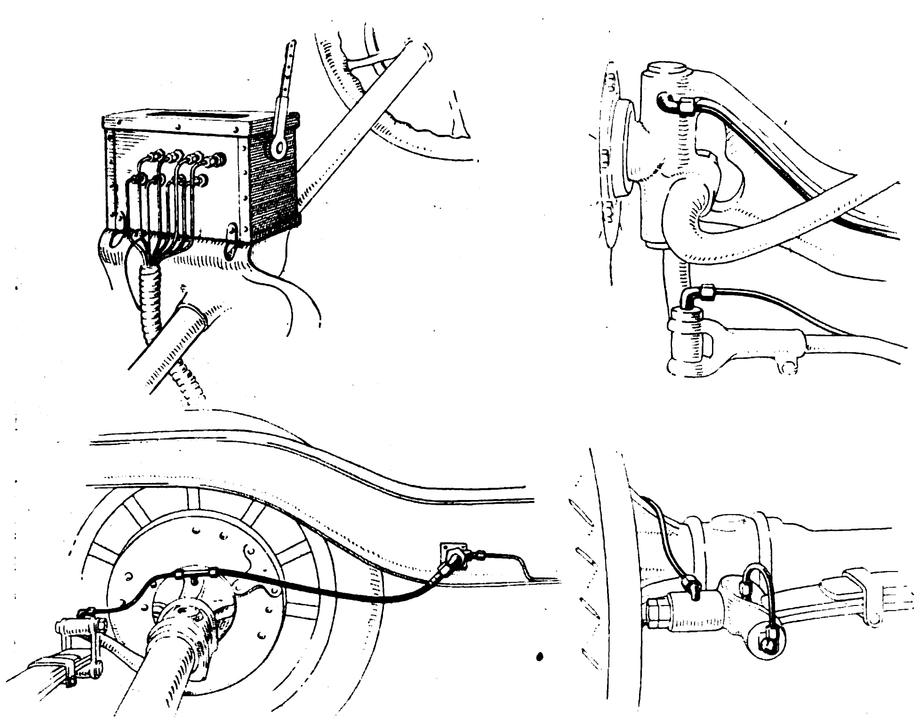
HIGH lights in the development of chassis design as indicated by the show exhibits are improved chassis lubrication, greater simplicity, rattle elimination, lightness, increased strength due to the better disposition of materials and greater accessibility of adjustment.

Taken generally, engineers visiting the show are impressed with the cleaner and neater appearance of chassis, particularly in the lower and medium priced field. It is noticeable that a few of the newer cars in the very high-priced field have almost the same simplicity as the lower priced cars, but being larger and heavier are not so prone to use the Hotchkiss drive and consequently employ torque members which serve to make the chassis seem of a little more complicated construction.

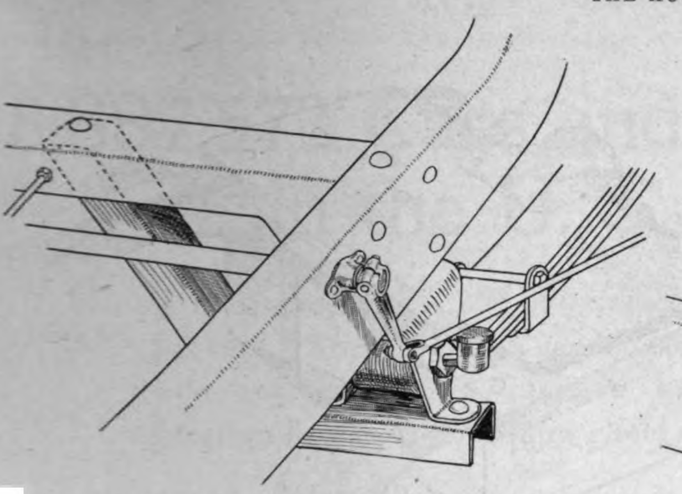
There is a very laudable effort throughout to clean up the details and lighten the chassis. This is being accomplished generally in one of two ways, either through the use of very neat drop forgings or by making a part which formerly served one purpose perform the work of two. In many instances these two ideas are combined and a drop forging is made which perhaps acts both to support the gasoline tank and the spare tire or perform some other dual service, thus saving weight.

The outstanding feature of chassis development, however, is the effort toward the simplification of chassis lubrication from the owner's standpoint. There is not a manufacturer who does not realize that vigorous steps are necessary on this part of chassis design to bring it up to a par with other parts of the car. The result is that on practically every chassis at the show some improvement in this respect is noticeable. There are probably fifty or more makes of cars shown with the Alemite system, a great many having adopted this oil-gun method during the year. The Saxon car is shown with the Romon automatic chassis lubricator as standard equipment.

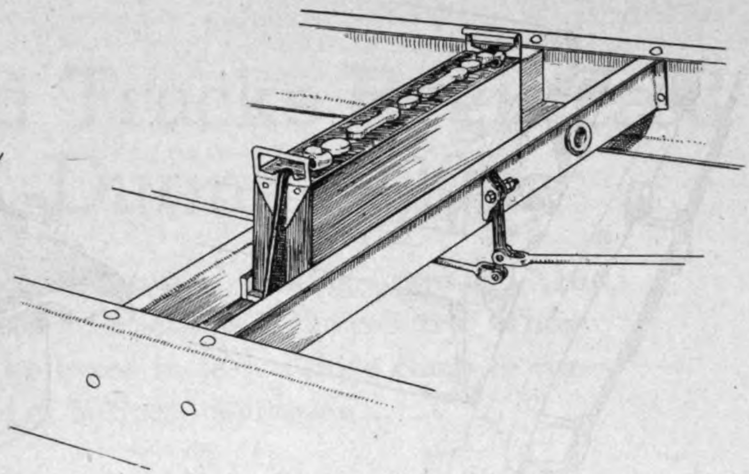
This system provides centralized lubrication for the entire chassis. In the Saxon installation the box-like reservoir is mounted on the steering column just behind the dash. The device is operated by periodically (about once every 500 miles) rocking a lever which works on a ratchet rotating the camshafts inside the reservoir. These in turn drive a series of pumps which are connected to the copper leads which run to all parts of the chassis. The pumps are plunger type and are depressed by the cams and return to normal position by means of springs. The oil is forced against a ball check in the intake and through a delivery passage into oil lines leading to the various points on the chassis which require lubrication. Ball checks are also located at these points so that the oil forced to these points remains there and also remains in the line between the reservoir and the bearings,



Romon chassis lubrication system on Saxon car and installation details



Unusual construction of spring bracket on Cleveland car



Cross member of frame serves as battery carrier on Briscoe

insuring immediate movement of the oil on operation of the pump.

To take care of the various steering, spring and axle points a number of fittings of a standard character are employed. The system displaces all the grease and oil cups on the chassis, the oil being lead direct to these points by the copper tubing and by flexible tubing connections to parts which have motion relative to the chassis frame. There are also special swivel connections at necessary points so that none of the tubing is under stress due to the oscillation of the springs, movement of the steering gear, etc.

The Fergus cars, with the centralized lubrication scheme, familiar to readers of AUTOMOTIVE INDUSTRIES, was also on exhibit and furnished another example in which a manufacturer has made the effort to eliminate the troublesome and often neglected task of chassis lubrication. This centralized tank takes care of the system by gravity, the flow of oil being from a tank which the makers state requires filling but once in every six months. On this car the springs are covered with leather boots and are oiled from the central system.

While the above mentioned cars offer some good examples of the solution of the chassis lubrication problem, there are some bad examples which may be justly criticized. There are some grease and oil cups still located at points where it is doubtful if even a vigilant owner would find them. After he had found them he would have to disregard the necessity of soiling his clothing and suffering great inconvenience in order to get the lubricant to the

points in question. Probably the location which is the greatest offender is inside the brake drum where some axle manufacturers still place the grease cup which takes care of the rear wheel bearing. Even on the stripped chassis it is hard to reach these cups, but when the body is mounted, the fenders put on, and road dirt has collected, it is a foregone conclusion that these points will be neglected. In fact the manufacturer might about as well save himself the price of the cups.

In simplifying the chassis, or in other words, cutting out the unnecessary parts, there have been some noticeable achievements. These have been particularly the case where the designer has been able to make one part do the duty of two. For instance, there are a great many instances where the cross member of the frame has served also as the anchor for the front rear spring hanger. On the Cleveland car this is very neatly accomplished. On the Briscoe the frame cross member has been extended and forms the front runningboard carrier. This is a nice bit of economy, but has the possible objection that in the event of the all-too-common collision, the owner's repair bill will be somewhat heavier, should he happen to be struck at this particularly vulnerable point.

Another clever bit of manufacturing economy on the Briscoe, which is noticeably good in this respect, is the use of the central U cross member as the battery retainer. This eliminates the customary cradle and certainly gives a firm support to the battery and at a very accessible point of the chassis.

On the Davis car there is a combined tire carrier and tank support which is a good example of making one part suffice for two purposes. Others make the rear cross member act in this capacity, either supporting the tire carrier, the tank or both. The new Lexington, which makes its first real public appearance at the show, uses the built up Z bar somewhat like the Marmon frame, but bolted instead of riveted for easy replacement in case of collision or other damage. In this type of frame the splash aprons, etc., are structural members.

There has been an increased stiffness in all types of chassis. One of the points which illustrates this quite clearly is in the increased use of tubular cross members both front and rear. On the Willys-Knight these are used on both ends of the chassis and are light, while at the same time they are good stiffening members and in the

8,887,572 Cars and Trucks Registered in the U. S. During 1920

A net increase of 1,291,096 vehicles is recorded, making a gain of 17.16 per cent. There is now a car for every 12 persons in the country. There were approximately $75,000,000 collected in fees. Huge climb in registration figures fails to show effect of business depression.

THERE are now 8,887,572 automobiles and trucks registered in the United States. This figure surpasses by over 300,000 most of the estimates made at the beginning of the year. While it was freely predicted that the number of vehicles would go well over 8,000,000, it was not expected that the 9,000,000 mark would be threatened so closely as it has been.

The figures show a gain of 1,291,096 over 1919, a gain of 17.16 per cent. On the basis of these new registration figures and of the 1920 census statistics, it appears that there is one vehicle for every 12.21 persons in the country. Thus, utilizing the full capacity of all the trucks, as

well as the passenger cars, it would be perfectly possible at the present time for every individual in the United States to go for a motor vehicle ride at the same time.

Over $75,000,000 have probably been paid in fees during the last year, although figures from several states are not available at this time. With 14 states missing, however, an actual total of $71,613,070 is recorded as received by the various states from automobile fees. This incomplete sum alone exceeds the 1919 total by $10,000,000.

New York, as usual, took a spurt during the last six months and again leads in total registrations with 651,696, after trailing Ohio, Pennsylvania and Illinois at the mid-year mark. Ohio is second, while Pennsylvania pushes California out of the third place position, which it occupied last year.

Three facts are outstanding in an examination of the detailed statistics. West Virginia has jumped to the top of the list in percentage gain in registration, having the surprising advance of slightly over 57 per cent.

The large advance of Texas in the last year is another feature. Only one state, Ohio, showed a larger numerical gain. With its gain of 96,324, Texas stands second in the list of registration gains, while a year ago it stood only thirtieth in the same list. This state also advanced in the total registration list from tenth to seventh place.

The other distinct gain noted was made by South Dakota, which now has one vehicle for every 5.24 persons in the state. Last year, at this time, South Dakota stood fourth in this list with one car for every 7.20 persons. This year, however, it has passed Iowa, California and Nebraska and has taken its place at the top. California dropped back of Nebraska.

The accompanying tables tell the preliminary detailed story of the

Gain in Registration 1919—1920

Ohio	105,769

huge 1920 increase. In the Statistical Number of AUTOMOTIVE INDUSTRIES will appear the revised figures for December 31, which will comprise an exact and accurate record for every state. Only minor changes will be made, however, as the figures in the accompanying tables are essentially correct, in most cases being exact.

The difficulty of obtaining accurate registration figures has been commented upon in previous years. Not only does every state law differ from that of every other state, but many states make wholly inadequate provision for administering effectively the laws that they have. The only final remedy for the confusion which now exists, of course, is a uniform national registration law.

In the meantime, however, AUTOMOTIVE INDUSTRIES has conducted an extensive investigation with a view to rendering its registration statistics as accurate as is humanly possible under present conditions. The registration laws and the methods of administering those laws in every state have been investigated, in most cases by personal visit; this being the first survey of this kind for this purpose that has ever been attempted.

The results of this investigation have been filed and correlated, so that the exact meaning of the figures sent in by any state can be accurately interpreted in making the tabulations.

The terms "transfer" or "re-registration," for instance, have a different meaning in various cases. In some states it is necessary to subtract from the figure given as "total vehicles registered" the figures for "transfers" if the exact number of cars in use in the state is to be determined. In other cases, to make this subtraction would render the figures incorrect. AUTOMOTIVE INDUSTRIES is able, as a result of this investigation, to interpret the figures of each individual state in terms of the practice of that state, thus making the figures accurate in the final tables. Another difficulty is to learn the actual number of cars in use in the country on any single date, since the registration year of the various states does not coincide; that is, there is no single date upon which the registration figures of every state have reached their highest point. A majority of the state registration years end on Dec. 31, however, and consequently that offers the best time for the making of a compilation.

The figures for Minnesota and for the District of Columbia need to be explained. In Minnesota the registration year and the fiscal year ends July 1. Up to July 1, 1920, Minnesota had a three-year, instead of a one-year, registration period. The total of registration simply grew over a period of three years, so that the Minnesota total last year was the result of two and one-half years' growth. The figures given in these tables comprise the number of registrations as of Dec. 31, 1920, and have been growing only since July 1, 1920, a six months' period.

This explains the apparent drop in registrations suffered in Minnesota; it is merely an apparent or "statistical" drop, however, and does not in any sense indicate that the actual number of cars in that state has decreased. The Minnesota law has been changed, however, and the registrations for future years should indicate more truly the actual number of vehicles in that state.

The fiscal year for the District of Columbia ends July 1, as well, and the figures given are for a six months' period. Consequently they are naturally smaller than the mid-year figures. It is impossible, however, to explain exactly the difficulties in the District of Columbia statistics, since the whole registration matter is in an exceedingly confused state. It is sufficient to note, however, that no special significance should be attached to apparently radical jumps or falls in the registration figures for the District of Columbia.

A table showing the number of states which register tractors and trailers and the number of these vehicles in each state is being prepared, but complete data are not available immediately. A comparative table of motorcycle registrations for the last three years will also be presented in the Statistical Number.

A CORRESPONDENT of *Der Motorwagen*, who visited the recent automobile show in Copenhagen, noted the following prices for cars of different size, quality and nationality: A Ford car with electric light and starter, 5600 crowns (one crown has a nominal value of 27 cents); a small German Wanderer, 7000 crowns; a French Citroen four passenger car with electric equipment and a piston displacement of about 95 cu. in., 10,500 crowns; a British Calthorpe of the same size, 14,000 crowns; a German Opel of the same size, but without electrical equipment, 9000 crowns; an 8-25 Fiat with electrical equipment, 30,000 crowns, and a 10-30 Mercedes limousine, 32,000

The above prices are in part the result of the remittance embargo on all luxury articles which has been in force in Denmark for some time. No automobiles can be imported at present and the prices asked are controlled more by the pressure of the demand than by factory prices.

Belgian Show Includes New Cars With Many Previously Exhibited

Newer chassis are mostly equipped with eight or four cylinder engines having overhead camshafts, separate heads and block castings which serve to enclose the vertical shaft drive. Aluminum webs and dash form separate engine compartment on some expensive chassis. Many novelties and refinements in spring suspensions, braking systems and steering gears.

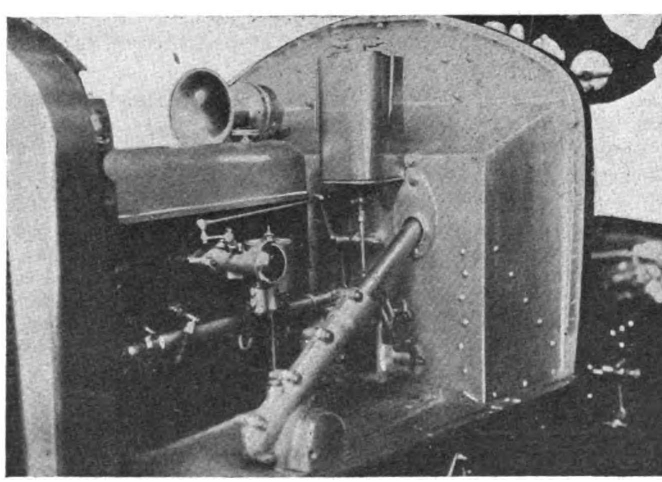
By W. F. Bradley

BELGIUM possesses less than a dozen automobile factories employing about 8,000 men (with another 7,000 in body and accessory works and forges), hence an invitation had to be sent to foreign manufacturers in order to fill her first post-war automobile show. The exhibition was held in the Palais du Cinquantenaire from Dec. 10 to 19, and was officially visited by the King. It was supported by every Belgian manufacturer, but these were outnumbered by foreign makers. France had the biggest share in the show, with 75 exhibitors of passenger cars; America had 14 car makers, Belgium 10, Italy 6, Great Britain 4, and Holland and Switzerland one each. In addition to passenger cars, the show comprised truck, tractor, body and accessory sections, with a total of 309 exhibitors. This constituted a record, for at the last show, held just before the war, there were not more than 200 exhibitors.

Since the French show of a year ago there have not been many changes in design, and inasmuch as most of the leading continental manufacturers were represented at the recent Olympic show, it was not to be expected that very much in the way of novelties and new refinements would be found on other than Belgian exhibits.

The spirit of enterprise and determination shown by the Belgian people in getting back to work is remarkable in view of the fact that no special protection has been afforded. Unlike any other country in Europe, Belgium has the same import duties as before the war, with the result that foreign competitors have been able to step in and secure an important place in her market. The greatest change since pre-war days is in the importation of American cars. Before the war these were practically unknown in Belgium, whereas at the present time at least 20 makes are selling in this market. America has created this position for herself despite very adverse rates of exchange. She had in her favor, however, the ability to make deliveries at a time when other nations were not producing.

The position of France on the Belgian market has not undergone any appreciable change. Exchange is slightly in favor of the French manufacturer, but it is only during the last six months—or since the depression set in—that he has been in a position to export. England has not changed her position in this market, and does not do a great volume of business. Her motor bicycles and motor accessories seem to be more appreciated than her cars.



Beck overhead valve engine

Outside the Belgian exhibits the only entirely new cars at the Brussels show were the Italian Ansaldo; the French Fonck and the Beck. Lorraine-Dietrich showed the latest type of light six cylinder. Renault has made some changes on his six cylinder. Instead of underslung semi-elliptic springs, this car now has cantilevers, placed diagonally in the frame and, instead of being shackled, having their ends carried in rollers. Another change in this model is in the radiator, which instead of going right across the frame, behind the engine, now has its vertical tubes only to left and right of the last cylinder.

The Fonck is an entirely new production, established by the well-known French aviator, with the assistance of a former Hispano-Suiza engineer and the backing of the Jacob Holtzer Steel Company. Two cars are to be produced, a four and an eight-in-line, of the same general design but with the difference that the eight will have brakes on all four wheels and the four the usual brakes on transmission and rear wheels. Only the complete chassis of the four found a place in the Brussels show, the eight being limited to the engine and gearbox. This job is very high-class throughout, and is laid out as a well finished, lively, sporting model. Although the cylinders are only 3.1 by 5.1 in., it is claimed that the four cylinder model will attain a speed upward of 60 m.p.h. with a four passenger touring body. Modern design tends to keep weight down, but the frame members are heavy and very much deeper than would be considered necessary by an American designer. Evidently the engineer has sought, by adopting this deep section, to avoid the troubles of sagging frames and misalignment which have developed in some sporting cars when driven hard over French roads.

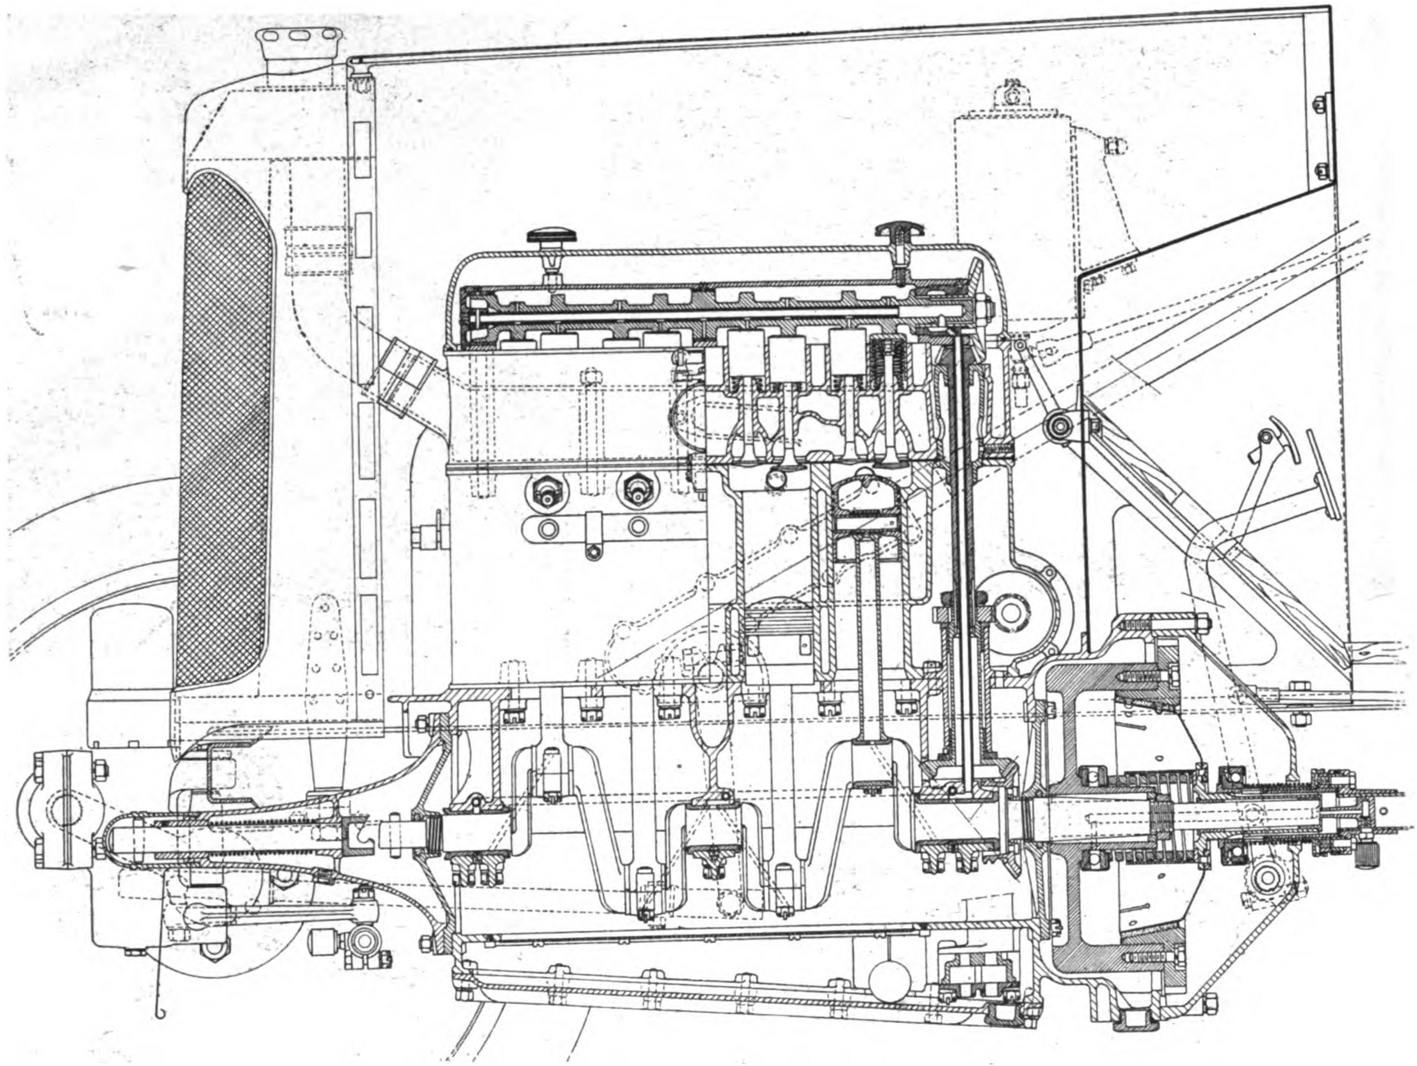
The cylinder block is so compact that it does not give the impression of having five main bearings for the crankshaft. A detachable head is used. It carries the eight vertical valves and the overhead camshaft. A central drive is employed for the camshaft, by the use of helical gears, the vertical shaft being inside the cylinder casting. There is a double housing for the camshaft; the inner one carrying the camshaft and being perfectly oiltight. The outer one which covers the whole of the valve operating mechanism, really serves only to add to the finished appearance of the engine as a whole. At the base of the vertical shaft driving the camshaft, there is a cross shaft which on one side drives the magneto and the generator and on the other side operates the water pump. The magneto and generator are placed parallel to the cylinders. A double distributer, delivering current to eight plugs placed horizontally on opposite sides of the engine is used. For the eight cylinder model the arrangement is not quite the same, for instead of the water pump being driven directly off the end of the cross shaft it is placed with axis parallel to the cylinders and in tandem with a second magneto. Aluminum alloy pistons are used and connecting rods are I-section forgings.

The unit powerplant of the Fonck models has three point suspension. Left hand steering and right hand control are employed, the change speed and brake levers being directly on top of the gear-box. The whole of the space between the engine and the frame members is covered in with cast aluminum plates. The aluminum dash comes right down to the engine base chamber and is bolted to it. All the air has to escape through the louvres in the side of the hood or through the wire gauze in the lower portion of the aluminum dash, and the only opening under the hood is for the fan belt, which is driven off the crankshaft. The steering gear passes through the dash, but without leaving any gap. The shaft carrying carbureter and ignition control levers is covered by an aluminum housing. The radiator is cowled, and the whole of the aluminum work is polished so as to make it as easy as possible to keep the engine clean. The aluminum instrument board has two tubular supports which slide into sockets cast with the aluminum dash, thus making it possible to adjust the instrument board to any desired position to suit the bodywork.

One of the features of the Fonck is the use of semi-elliptic springs which have their greatest width, 4.7 in., at



Longitudinal section, Beck overhead valve motor at Brussels show

the axle and gradually decrease to a width of 2.3 in. at the extremities. The springs are underslung, have no clips, and take the drive and the torque. With this arrangement, two universal joints are required. The propeller shaft is tubular and of large diameter. The wheelbase of this chassis is 122 in., but with the compact engine the available length for the body is 103 in. The eight cylinder has a wheelbase of 142 in.

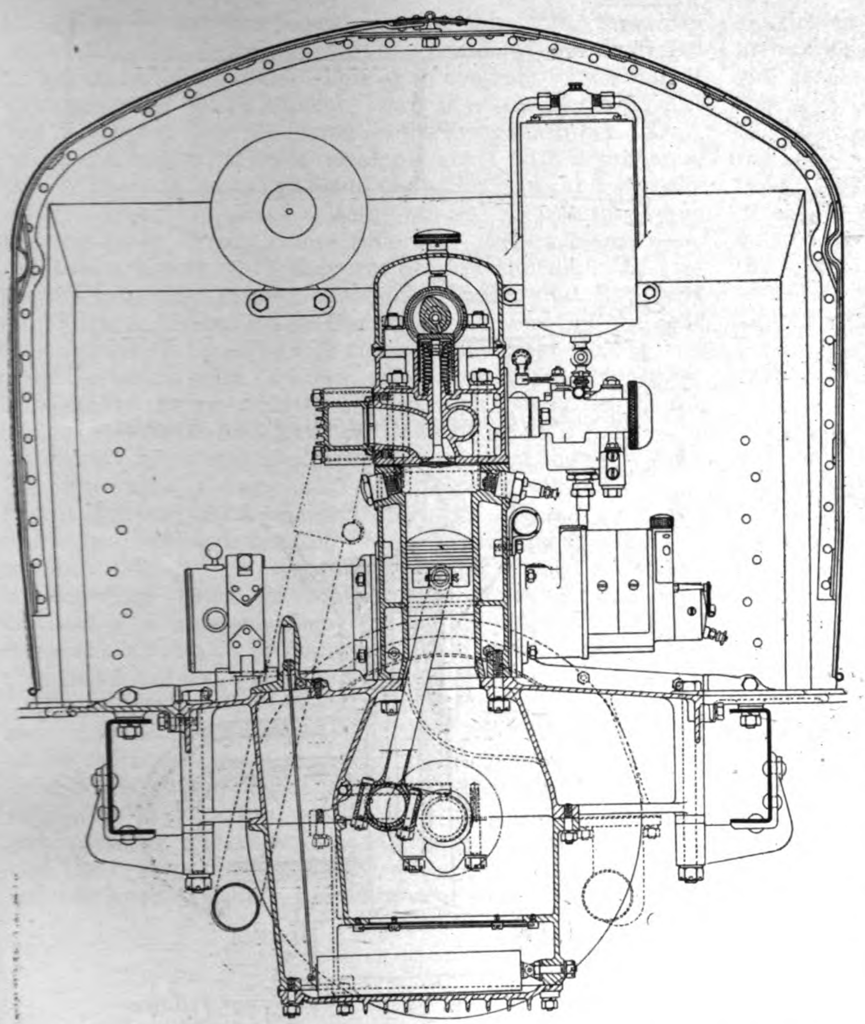
The Italian Ansaldo Car

Ansaldo, the largest general engineering firm in Italy, has entered the automobile field with what is considered in Europe a medium, general service, economical automobile. This is a class of car which has no counterpart in America, for it is smaller and better finished than the Dodge type. The four cylinders of the Ansaldo measure 2.7 by 4.7 in., are a single casting with the upper portion of the basechamber and have a detachable head with overhead camshaft. The vertical drive shaft is within the cylinder casting. The water pump housing is cast with the cylinders, and is driven by the cross shaft which also operates the magneto. The engine has three point attachment to the frame and is a unit with the clutch and gearbox, the latter having only three speeds, instead of the four commonly employed on a car of this type in Europe. It is rather unusual, from the Italian standpoint, to find that Hotchkiss drive is employed. Detachable wood wheels are also an unusual feature, for Italian makers show a strong preference for metal.

It is understood that this car was designed to be produced at 7,000 lires, but the price in Italy is now more than 30,000 lires.

There is a lot of original work in the Beck light car, a small four cylinder (2.5 by 4.4 in.). It has block cast cylinders with detachable head and overhead camshaft driven by a vertical shaft and bevel gearing from the rear. By this arrangement the electric generator and the magneto are placed at the rear, but there is no loss of accessibility, for the distributer end of the magneto is outwards, directly under the steering column. Valve operation is direct, without the use of followers. A piston type head is screwed into the extremity of the valve stem to give adjustment. It is guided in the camshaft housing so as to provide for the thrust occasioned by the directly operating cam. Beck has adopted the plan, which up to the present has been confined to makers of costly cars, of extending the crankcase webs up to the frame members and bringing the cast aluminum dash down to the engine, so as to make a completely enclosed compartment. By this arrangement all the hot air from the engine has to escape through the sides of the hood.

Another peculiarity of this car is the method of uniting gearbox and differential housing, carrying the load on a tubular axle, and driving by transverse shafts with universal joints. Coil springs are used all around for suspension, in place of laminated springs. All four are enclosed in dust-proof and oil-tight housings, and the coils are of variable thickness, increasing in section as the center is reached. This gives a suspension which in a certain degree automatically adjusts itself to the load. One



Transverse section, Beck four-cylinder overhead valve motor at Brussels show

for a high class job the results justify the extra cost compared with a forged shaft. There is a flexible connection between engine flywheel and a clutch member. Heavy rubber rings, about six in number, are recessed in the rear face of the flywheel, and these receive studs on the forward face of the clutch member. The rubber rings are set up with graphite and, it is declared, there is no tendency for them to harden under this service. The dominating feature of this chassis, however, is the system of braking on all wheels, together with the cantilever suspension and attachment of the rear axle to the frame. The four wheel brakes are the design of Engineer De Coninck and were worked out during the four years the Germans had forcible possession of his factory. Excelsior brakes diagonally by means of cables; one cable being brought from the right front wheel over a double lever on the brake pedal shaft and thence to the left rear wheel. In this way the effort applied to opposite wheels is always equal, and even if one cable should break, two wheels on opposite sides would hold and the car would not deviate from its straight course. Merely for holding the car when in a stationary position, there is a second control to the rear wheels by lever.

At the front the brake camshaft is received in the lower portion of the axle and passes direct into the brake drum, so that there are no universal joints on this braking system. The four main brake levers with yoked ends are telescopic, so that when dismounting it is not necessary to touch the yokes but merely knock out a pin and pull the two telescopic parts apart. Another unusual feature, which it is declared has given excellent results, is the use of alternating sections of cast iron and fabric for brake lining. It is found that this stops the screaming common with metal to metal

of the mechanical features of the car is the entire absence of keys and keyways, all shaft fittings being tapered and splined.

Among the Belgian makes one of the most distinctive cars is the new Excelsior, a high-class six 3.3 by 5.5. in. The engine is an L-head type in one casting, with a counterweighted crankshaft carried in four bearings and machined entirely out of the solid. Excelsior maintains that

shoes, and that the fabric is rendered more efficient as it becomes impregnated with iron dust. The hardened steel face plates on the brake shoes, which come in contact with the brake cam, are double wedges with notches giving one millimeter adjustments. Finally, the brake shoes are slightly eccentric. It is claimed that with perfectly concentric shoes only a line contact is obtained, whereas if made slightly eccentric the slight spring which sets up

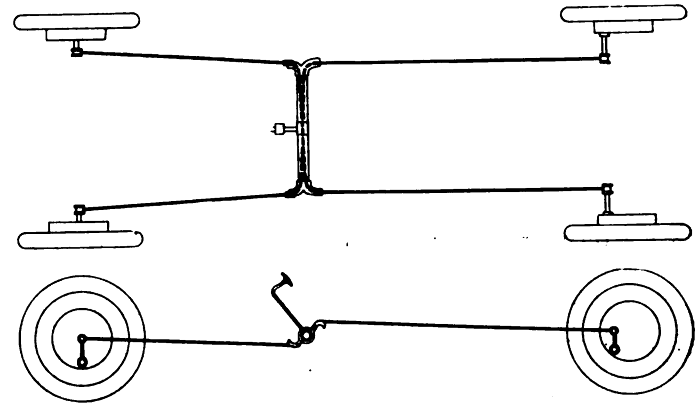
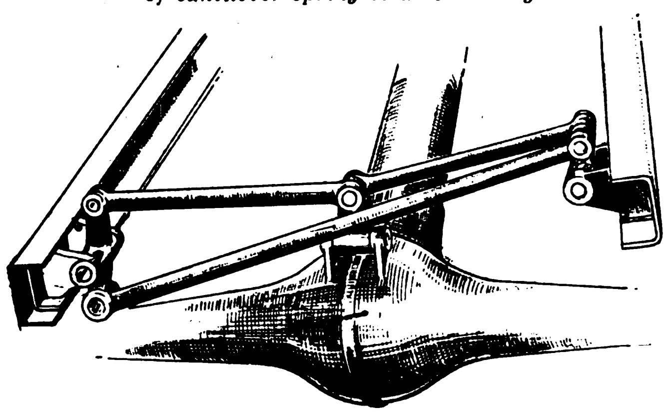
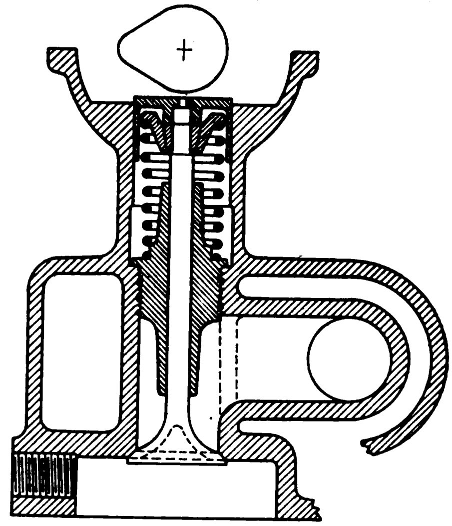
Excelsior car, showing ball and socket attachment of cantilever spring to axle housing



Four-wheel braking system on Belgian Excelsior



Compensator on Belgian Excelsior



Miesse overhead valve with guide for follower

in the shoes assures the entire surface being made use of for braking.

The cantilever springs on the Excelsior are not rigidly fastened to the axle housing, but are secured by a short connecting rod with ball and socket at each end, the whole of the mechanism being enclosed and fed with oil from a reservoir containing a six months' supply. By this attachment the axle is free in relation to the main frame members, but in conjunction with this flexible attachment, use is made of a compensating stabilizer consisting of two connecting rods from the upper portion of the differential housing to links on the inside of the main frame members, the whole forming a parallelogram, as shown in the illustrations. This device leaves the axle free to move in a vertical plane, but eliminates all lateral movement, the practical result being that all the advantages of cantilever springing are obtained without any tendency for the rear end of the car to roll when running fast. Tests show that when taking turns at high speed the rear wheels track perfectly and show none of the tendency to skid so common with the usual attachment of cantilevers.

It has been necessary, with this device, to stiffen up the rear end of the frame and to obtain a very substantial attachment, but the results obtained are remarkably satisfactory. All the bolts used with the stabilizer, as well as every spring shackle bolt on the car, are adjustable for lateral play. In the case of a shackle, instead of the bolt being passed directly in the cheeks of the shackle, it is carried in two hardened and ground sleeves, one of which is fixed and the other adjustable laterally. This allows a spring to be mounted with plenty of lateral play, all of which can be taken up in the adjustment, and any subsequent wear can be taken up in the same manner.

Metallurgique, while maintaining two smaller types, has produced an entirely new chassis with a four cylinder 3.9 by 6.29 in. engine. It is understood that this engine will be replaced, at a later date, by a six-cylinder of the same bore and stroke, mounted in the same chassis. Features of this new product, which is a really high class job, are unit construction of engine and gearbox, with centre control; brakes on all four wheels; cast aluminum dash and floor boards; a new forged full floating rear axle; and underslung semi-elliptic springs of exceptional length. Probably these are the longest springs ever fitted to a car—70 in. long and 2.7 in. wide. They are mounted under the axle and placed directly under the main frame members.

The growing practice of extending the crankcase webs right up to the main frame members has been adopted by Metallurgique. The cast aluminum dash, however, is not extended down to the engine but slopes away rearwards so as to form the toeboards. A recess is cast in the forward face of the dash to carry the vacuum feed tank, and the polished aluminum instrument board is secured to the dash by tubular steel arms. This method of using cast aluminum for dash and toe boards and also for filling in all the space between the engine and the frame members is one of the refinement features of the show. The steering gear box of the Metallurgique is bolted directly onto the top of the extended crankcase webs, a well being formed here to receive the housing, and a hole being provided for the passage of the main steering arm. It is worth noting that the oil filler on the steering box has a hinged cap, 3 in. in diameter, held down by a spring. Metallurgique drives water pump and magneto from a cross shaft in front and places the electric generator and starter respectively to left and right of the gear box.

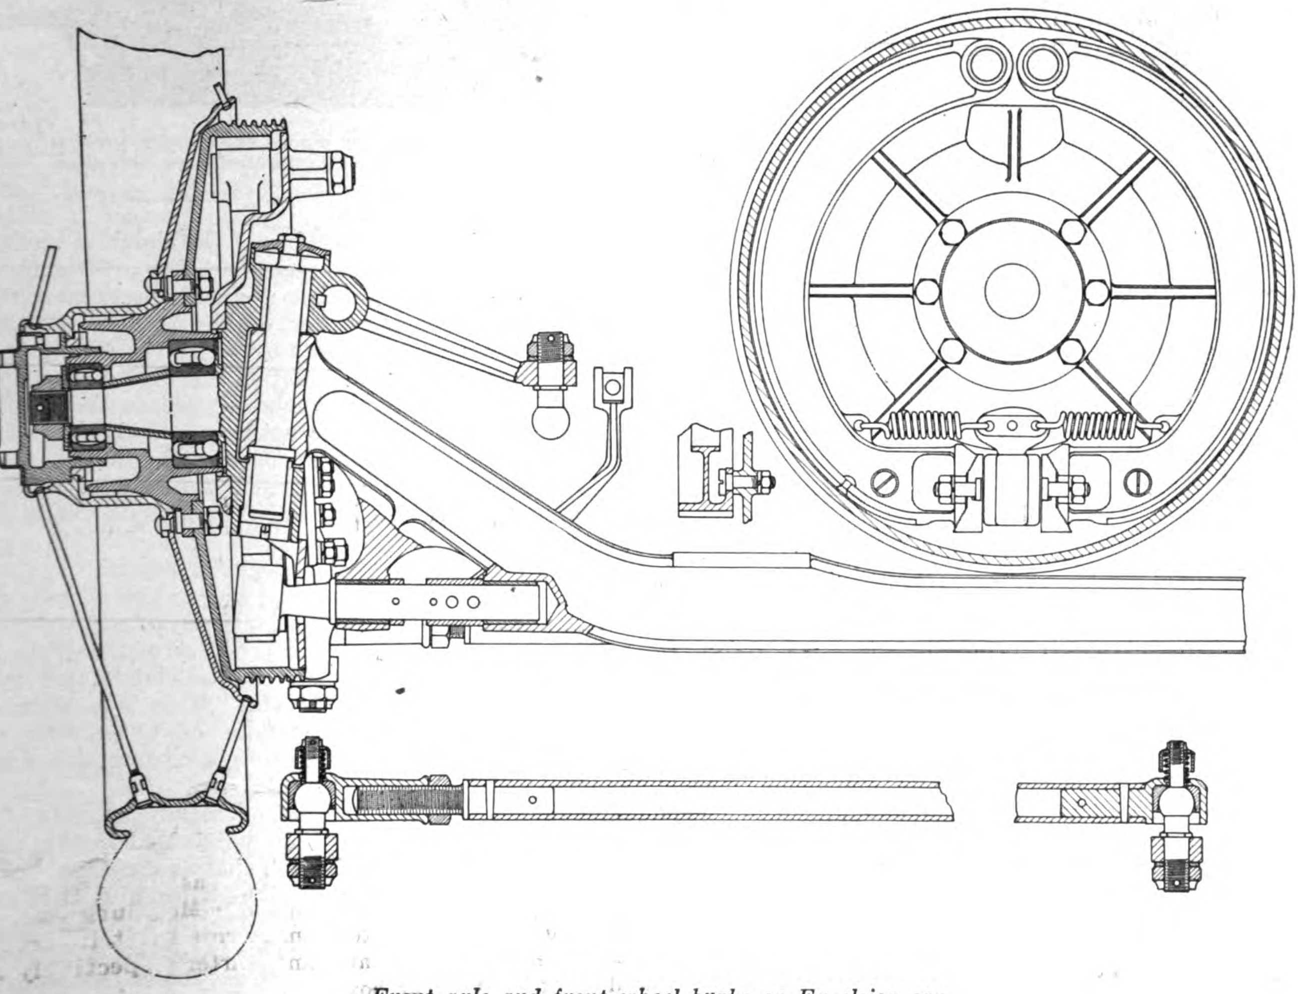
Brakes on all four wheels are of the Isotta-Fraschini type, with the brake camshaft for the front wheel carried in bushings in the axle. This is in contrast to the Perrot system, under which the cam shaft is at the highest point and is supported in a bearing on the frame member. This, of course, necessitates a telescopic shaft with a universal joint. Steel ribbons are made use of on this car for brake control, but instead of placing these horizontally, and passing them through fibre rollers or other support, as is usual to prevent whip, they are placed vertically. In connection with the brakes, it should be noted that front and rear ribbed drums are of the same diameter, but the rear ones are twice the width of those on the front wheels, and carry an extra pair of shoes, which are operated by lever. This makes it possible to comply with the necessity for locking the brake when the car is standing on a hill.

Other front wheel braking systems seen at the show were Hispano-Suiza, Delage and Talbot-Darracq, all built on the Perrot license; the Bellanger, which has its steering pivots inside the brake drums, the Isotta-Fraschini, and the Excelsior. Other firms announcing front wheel brakes but not showing them on their chassis were Fonck, Spa, D'Aoust and Miesse. Some half dozen other Continental firms are known to be negotiating for Perrot licenses, but they have not yet made public announcements.

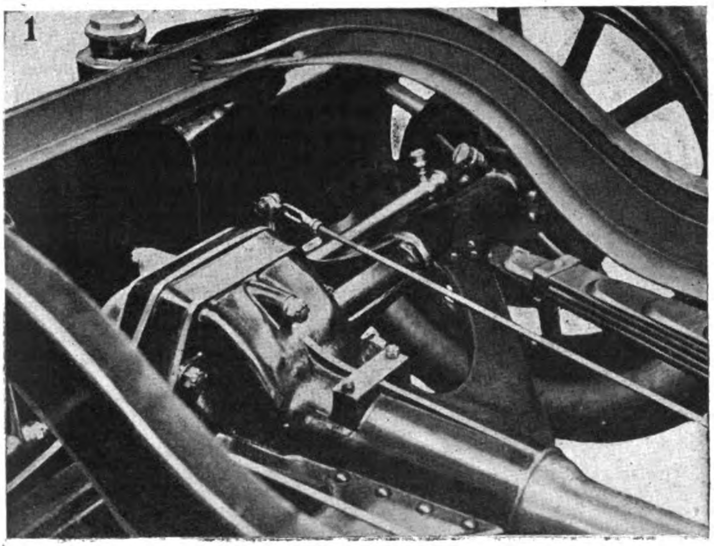
Miesse, one of the oldest of the Belgian firms, has two new engines, with respectively four and eight cylinders, of the same general design and the same bore and stroke. It is a growing practice, when adopting an eight-in-line engine, to make a four at the same time and of the same size. Miesse dimensions are 2.7 by 5.1 in., and for each type the cylinders are a block casting with detachable head and overhead camshaft, driven by a vertical shaft and bevel gearing inside the cylinder casting. The show models have aluminum cylinders with liners, but it is declared that these will be abandoned for cast iron. In common with several others at the Brussels show, Miesse does not use a pivoted follower between cam and valve, but has a nut screwed on the end of the valve stem, and mounted on this a piston-type hardened and ground cap, which is well guided in the detachable head. This eliminates the thrust and consequent wear occuring when the plate is screwed directly into the valve stem.

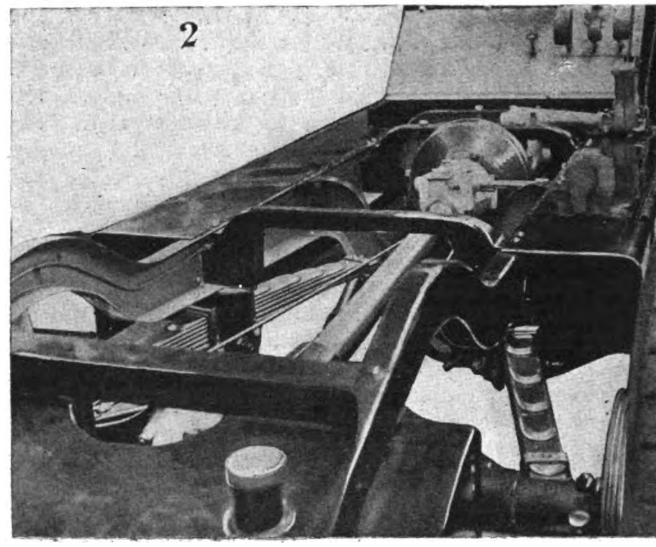
Miesse drives the two blade fan from the vertical shaft, with a friction clutch interposed. A rather unusual feature is that the steering gear housing is cast with the engine base chamber, being placed on the right hand forward arm, just below the magneto driven from the cross shaft. The complete chassis of this new type was not ready for the show, but according to information obtained its chief feature will be front wheel brakes with hydraulic operation.

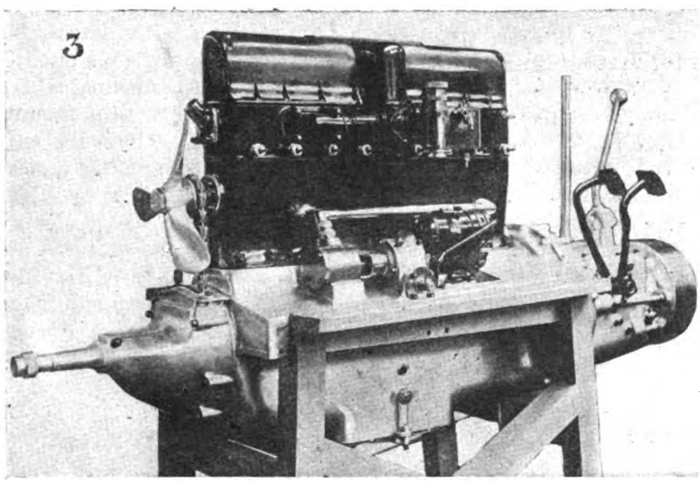
A semi-racing type 3-litre engine is the feature of the D'Aoust production. This car was not shown complete, only the engine, clutch and gearbox unit being on exhibition. Cylinders are a block iron casting with detachable head, and an overhead camshaft in an aluminum housing. A vertical shaft at the front drives the camshaft which operates three valves per cylinder. The method of mounting the two magnetos is rather unusual. They are carried on a platform cast with the camshaft housing and to the left and right of it, each magneto being driven by silent chain from the rear end of the camshaft. This design brings the magnetos to the highest part of the engine and has probably been adopted for the accessibility it provides and the possibility of quick change and adjustment when racing. This engine is built to the designs of a French

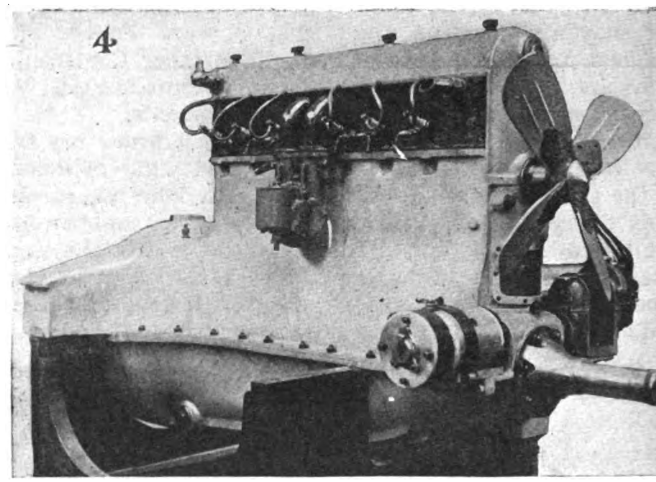


Front axle and front wheel brake on Excelsior car









1—Renault reinforced rear axle and cantilever springs. 2—Renault diagonally placed cantilever springs. 3—Fonck eight-cylinder engine. 4—Spa new six-cylinder engine which is all aluminum with the exception of detachable head

specialist, and will, it is declared, be entered in the leading 183 cubic inch races of the year. In addition to this special sporting type D'Aoust has a medium size car on quite standard lines.

Minerva, the biggest producer in Belgium, shows nothing new, for this firm had its post-war models out for the Paris show of a year ago, and exhibited the same at the recent London show. There are two models, with Knight engines of four and six cylinders, respectively.

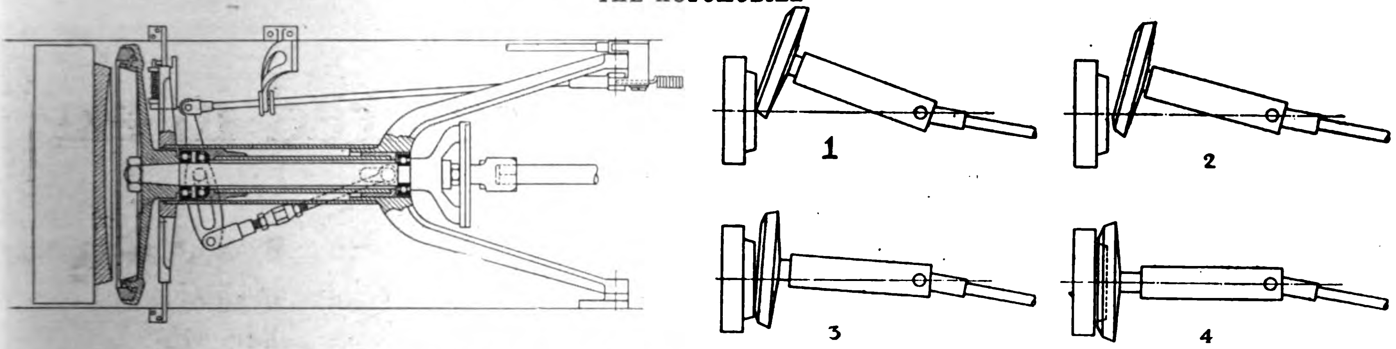
The F. N. Company exhibited a new model which also was uncovered at the recent London show.

Belgian makers generally are paying more attention to high class, almost luxury types, than to popular models. There is no firm with a program similar to that of Citroen in France or Bean in England. Somua has a popular type, but the firm does not have big production means. Practically the only other firm attempting to get into the popular class is Belga, a concern established since the war and marketing a light car with an unusual and interesting type of friction transmission.

The engine is a Ballot of 2.5 by 4.7 in. bore and stroke, carried on a subframe, and the rear axle is a standard type, with Hotchkiss drive. In place of the usual gearbox there is a friction transmission. When driving on top a cone clutch is in engagement and the drive is straight through to the rear axle. The driven member of the cone clutch has two friction surfaces; the cone used for normal driving on top gear, and a ring of canvas and rubber mounted on the forward face of this disc. When the cone has been disengaged, the driven member of the clutch is inclined so as to bring the ring in contact with the driving member, and the lower the gear ratio required the greater the inclination, until dead center of the driving member is reached. Reverse is obtained by taking the plate past dead center. The necessary inclination is provided for by carrying the clutch shaft in a yoke pivoted to the subframe. The clutch is used in the usual way, and changes of ratio are obtained by a straight movement of the lever. It is claimed that this device has been on the road for a year and has given perfect satisfaction. The direct drive is no departure from standard practice, and if the friction gear has stood up to tests, the Belga ought to become popular, for it is cheap to build and gives a wide range of gear ratios.

Ballot, the French specialist, took advantage of the Brussels show to come forth as a producer of complete power plants. His unit comprises engine, clutch and gearbox ready for fitting to a sub-frame. This firm is now also specializing on motorcycle units of two-stroke engine, clutch and gears in one. House lighting sets also are being produced.

Belgium had a high reputation before the war, for customs bodies, and this has been maintained in the post-war products. Numbers of English chassis are sent across the Channel to be fitted with Belgian bodies, and this accounts for a greater predominance of English types that is seen elsewhere on the Continent. This is particularly noticeable in all weather bodies, which are not much favored by Continental motorists, but are in great demand by English



Friction transmission used on Belga light car

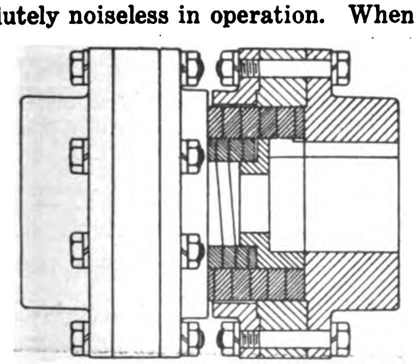
motorists. There is only a mild tendency towards the concealed top, and, speaking generally, it is adopted only for sporting type two and three seaters. The Etablissements Generaux showed some very fine examples of running boards and tool boxes in a single stamping, thus avoiding the sharp angles which are unavoidable when the tool box is a separate construction placed on the running board. This firm showed runningboard, tool box, two fenders and valance in one piece without any visible bolts and screws, giving a very good effect on cars with rounded lines.

The Bosch magneto was seen on two cars, one Belgian, the other Dutch. Bosch, however, did not have a stand. Switzerland came into the field as a magneto producer with the Scintilla. On this instrument the permanent magnet rotates, while the contact breaker, the windings and the condenser are fixed. The distributer is at the driving end of the magneto, thus allowing shorter wires to be used than when placed at the opposite, and outer, end. A feature of the Scintilla is the ease with which it can be dismounted and assembled.

An All-Metal Flexible Universal

A NOVEL type of universal coupling has recently been placed on the market by the Karge-Baker Corporation. The flexible portion of this coupling consists of two coil springs wound in opposite directions, placed concentrically. The ends of each spring is welded to a header attached to the driving and driven flanges or sleeves respectively in the manner shown in the accompanying cut. It is claimed that the drive is carried through the continuous coil, but when under torsional load the coils of the outer spring expand or contract depending upon the direction of turning and grip either the outer casing or the inner spring, thus transmitting torque to the driven member. The particular advantages attributed to the coupling are the cushioning effect of the springs in picking up the load, the fact that no lubrication is required and that the efficiency is high. The design is such that perfect balance is obtained and the permanency and reliability in operation are said to be unquestioned.

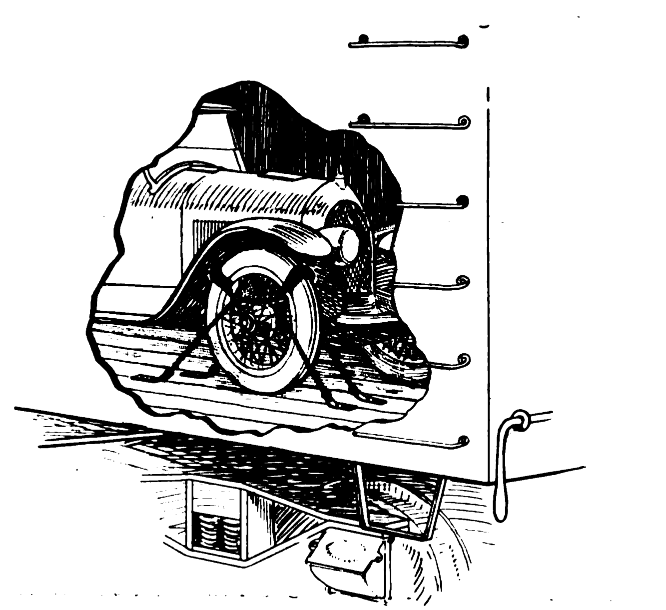
The driving coil is constructed of heat-treated alloy steel, accurately ground to size. The flexible arbor or smaller coil is ground to assemble with accuracy inside the driving coil. The driving coil is so constructed that the thrust caused by forward and backward shaft movements is taken up by the spring. The couplings are designed to allow a maximum driving angle of about 10 deg. or a 1/8 in. offset, and are said to be absolutely noiseless in operation. When picking up the load the driving end of the joint moves about one-tenth of a revolution before the driven end moves. A certificate of tests made by the French Government laboratories show that a Karge coupling having a coil of 52 mm. dia. and 9 turns transmitted without appreciable power loss from 8 to 24 hp. at speeds of 925 to 1560 r.p.m. respectively when running at an angle of 11 deg.



Sectional drawing of flexible universal coupling

New Device in Use for Shipping Automobiles

A NEW device for fastening an automobile in a railroad freight car consists of a chain tie gripping the wheel and bolted to the floor of the car. This device has recently been placed on the market by the Carbo Steel Products Co. This chain is applied to each wheel of the car, the illustration herewith showing the manner of application. A rope winding around the tire gripping section of the chain protects the tire from abrasion.



Device for fastening automobiles in freight cars

Cylinder Blocks Manufactured in an Efficient Manner

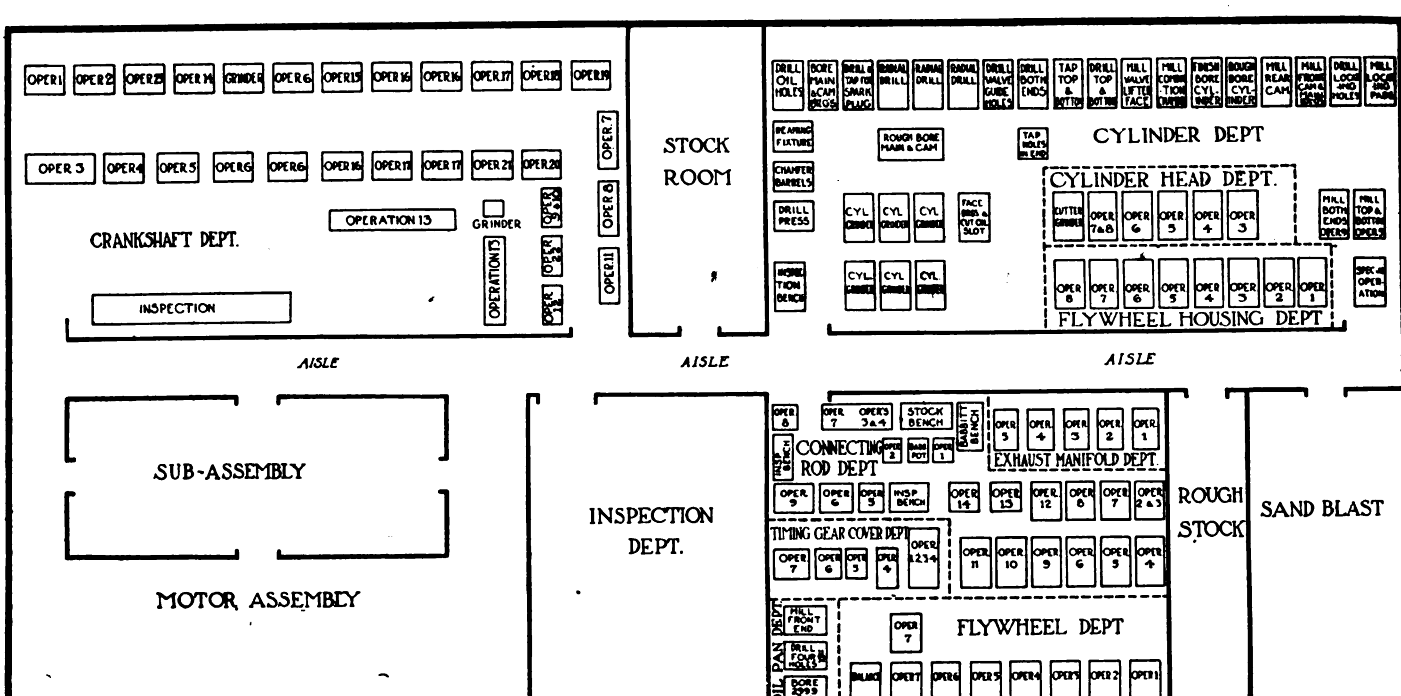
Engines for the Lexington car are being produced in a specially designed factory, which embodies many interesting production features. The following article describes in detail the manufacturing processes used in machining the cylinder block castings for this engine.

By J. Edward Schipper

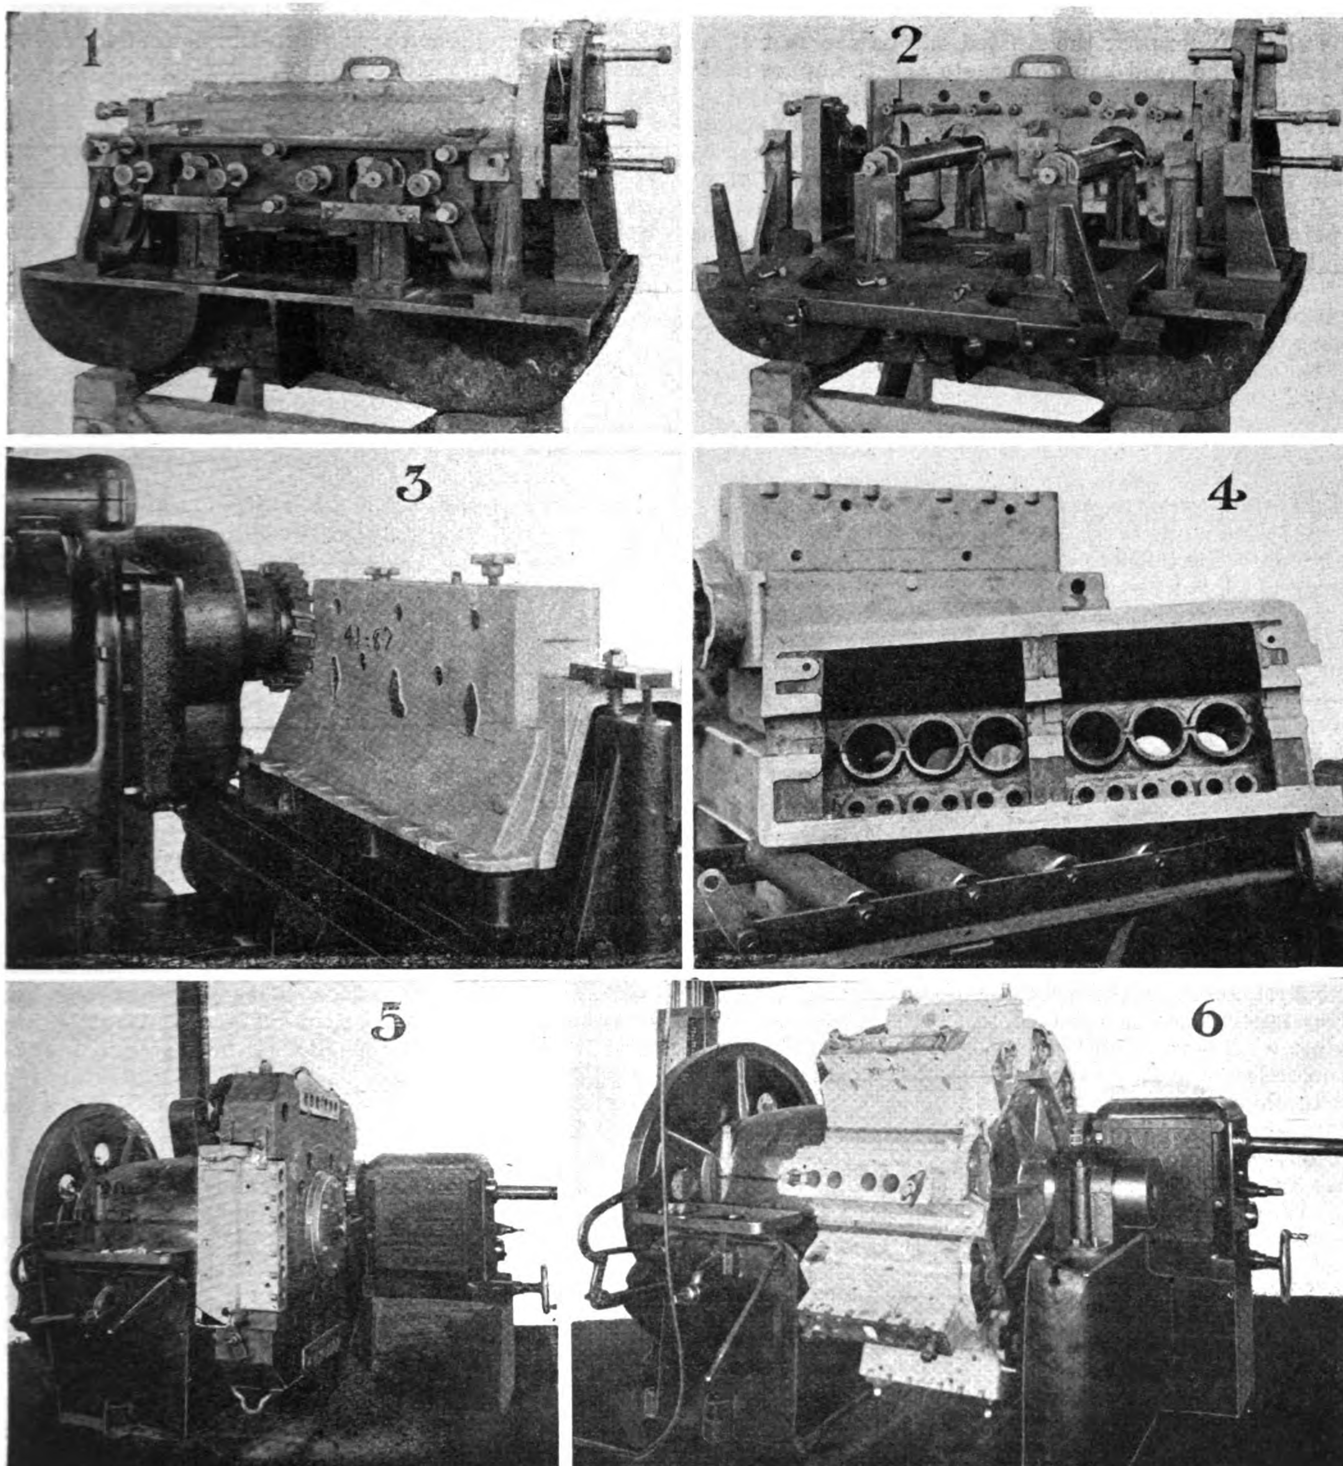
THE production of engines for the new Lexington car is taken care of in a specially designed factory with an output capacity of from 40 to 50 engines per day. The concern producing the engines is the Ansted Engineering Co., which has buildings adjacent to the Lexington factory and, in fact, is very closely allied with it. Inasmuch as this factory has been designed particularly for the production of the Ansted engine, and with an eye toward smooth production up to capacity, it incorporates some very interesting production features which have tended to make it a very efficient plant.

In the general layout the plant is divided into two parts, which may be called production and assembly. These two main parts occupy, roughly speaking, the two ends of the plant, while at the center is the finished stock store-room which acts as a clearing house for all of the material entering the assembly department. The parts which are manufactured in the factory enter this clearing house, as do also the parts which are received from outside sources. The plan of the factory shown herewith indicates this central stock-room and the inspection department from which the parts pass into the stock-room. Both the finished parts received from outside and those manufactured in the plant itself go through the inspection department into the finished stock-room, from which they are drawn for assembly. As there is a railroad siding along the side of the plant, the receiving department gets the material directly from the freight car from which it is passed to the inspection department and into the stock-room with a minimum of movement, as the unloading platform is at the entrance to the inspection department.

This general scheme gives an efficient layout which is backed up by some interesting installations of special machinery for the manufacture of the different parts. It is beyond the scope of this article to take up in detail the manufacture of all the parts which enter into the manufacture of the engine, but it will be of interest to select one and follow it through, to show how space has been conserved and efficiency promoted by the use of machinery particularly adapted to the needs of the product and incorporating the latest devices for rapid handling of the parts. To carry out this purpose the cylinder block operation has been chosen as perhaps presenting the greatest manufacturing difficulty and, at the same



Layout of Ansted engine plant



1—A cylinder block in the rough casting inspection jig. When the cylinders are received they are given a quick going over at the finish points with white cold water paint. This inspection jig in a very few minutes will go over each casting thoroughly and scribe the finish line of each important finished surface. This tells conclusively whether the cylinder block will machine. 2—The rough casting inspection jig without any casting in it, giving a good idea of its construction. 3—The first machine operation on the cylinder block. On the rough casting inspection jig and on the fixture for the first machine operation the location is from the cored holes of the cylinder barrels. This is contrary to usual practice and might be regarded as unnecessary, but is done to secure uniform cylinder walls and the balance of the machining on the cylinder block is brought to the barrels so there is no question of squareness on the entire job. This operation mills off the locating bosses on the side of the cylinder block. 4—In addition to the locating bosses there must be other locating points to fix the cylinder block for drilling and boring operations. This locating is done by means of two ½-in. reamed holes in the bottom of the cylinder block. These holes are shown in this print. The operation of drilling them is done by a standard machine and fixture. 5—Milling top and bottom faces on a Davis rapid miller with a rotating table capable of carrying four blocks at a time. 6—End milling a block on a Davis rapid milling machine capable of handling 240 blocks a day because of its continuously rotating table carrying nine blocks

time, involving the necessity for particular machine installations.

The six cylinders for the Ansted engine are cast in a single block, the head being separate and the upper half of the crankcase a unit with the block. Up-to-date methods are utilized from the very start in the handling of this block. As soon as the block is received from the foundry it is submitted to an inspection by means of a special gage which checks the amount of metal at all of the points at which machining is to take place. This special gage locates from the inside of the No. 2 and No. 5 cylinder barrels, and by stops against the valve tappet bosses. Fixed in the gage are a number of scribes to check the amount of metal at the points to be machined and also stops which must come against the various surfaces of the casting to show that there is sufficient metal at all points. Some castings, when they come to the plant, contain irregularities which render them unfit for use. This inspection gage catches such irregularities. Consequently, the cost of the block is not increased by machine work being followed by a rejection which could have been determined beforehand. This cylinder block ranges around 220 lb. in the rough. The finished block ranges around 180 lb. An average of 40 lb. of metal is removed from each cylinder block.

The blocks are allowed to age before being passed on to the manufacturing floor. They are kept in a special receiving room adjacent to the railroad siding, and after they have aged are sand blasted and passed out to the manufacturing floor on Standard roller conveyors. They are then given a coat of special dirt-proof paint. This is a Rogers product specially designed to keep the inside of the block clean. It differs from the usual paint in that alcohol is used for the vehicle in place of turpentine.

Machine Operations

The first actual manufacturing operation on the Ansted cylinder block is interesting because, while it has nothing whatever to do with the actual finish of the engine, it lays the foundation for manufacture which results in sharp jig economy and, at the same time; is the beginning of a system of location which materially cuts down any chance of error. The operation is the milling of the locating bosses on the right side of the block. These bosses are put on the cylinder block for no other purpose than to form a basis of location, and in milling these bosses, the block is located from the No. 2 and 5 bores in the same way that it was on the inspection jig. The work is done on a Chesterlein No. 34 heavy type of plain miller. The bosses are milled off and give a surface which is square to the centerline of the No. 2 and 5 bores.

The block is then placed on the conveyor and taken to another milling machine, where the top and bottom faces are milled. The particular milling machine which does this work is an interesting type, owing to the rapidity with which it operates. It is a Davis rapid miller with a rotating table capable of holding four blocks at the same time, giving continuous milling. That is, while manufacture is going on the table can be loaded from the outside so that there is no necessity for stopping the machine for reloading. In this work the block is located from the locating bosses previously milled and from the No. 2 and 5 bores. The machine is capable of producing 12½ per hr., or 125 per 10-hr. day.

The Davis rapid miller takes two cuts, the first being the roughing and the second the finish cut, so that after the block leaves this machine it is capable of location from the top and bottom faces as well as the locating bosses. The faces of the crankshaft and camshaft bearing holes are next milled, the location for this work being from the center line of the casting between the No. 3 and 4 cylinder barrels and the bottom face. This work is done on a No. 34 Ohio miller capable of 62 per 10-hr. day.

The next operation is a foundation operation which establishes the location for all of the rest of the work on the cylinder blocks, and since it is utilized in this way, it does away with the shifting of location, which is apt to lead to trouble and which makes it difficult to trace down errors. The operation in question is the drilling of locating holes which are used only for this purpose. There are two holes ½ in. in diameter which are drilled and reamed on a Wickes Bros. drill. These two locating holes, together with the top and bottom faces, are used for practically all of the subsequent operations and give a very simple system of location, which has greatly helped in simplifying the jig and fixture requirements for manufacturing this block.

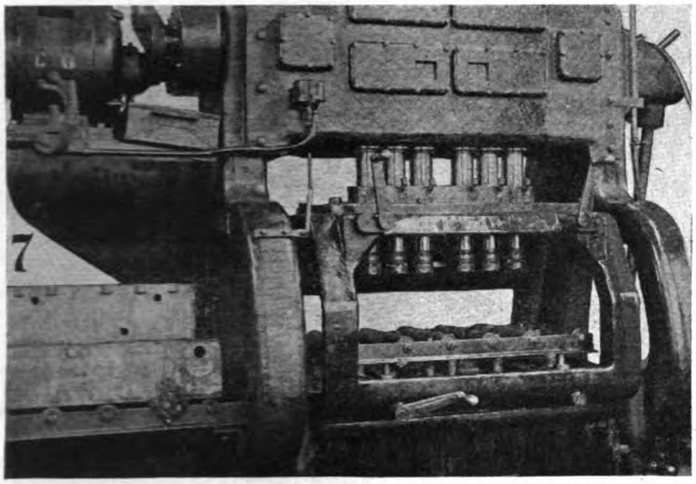
The block is end milled on both ends on a Davis No. 3 rapid miller. This milling machine holds nine blocks at the same time and has a continuously revolving table. The machine is capable of 240 blocks per 10-hr. day, taking both rough and finish cuts on both ends at the same time. For final finish, the blocks are passed to an Ingersoll miller which takes off .020 in. of the finish cut from the top and bottom of the casting. This machine is so arranged that an auxiliary cutter comes in after the timing flange has passed by and mills off the pump pad boss and the control lever bosses. The casting is put through the machine, standing on its side, so that the top and bottom milling are side cuts and the cutter for the pump pad and control lever bosses comes down from the top, after the timing flange has passed by. The limits on the top and bottom finish milling cuts are plus or minus .005 in.

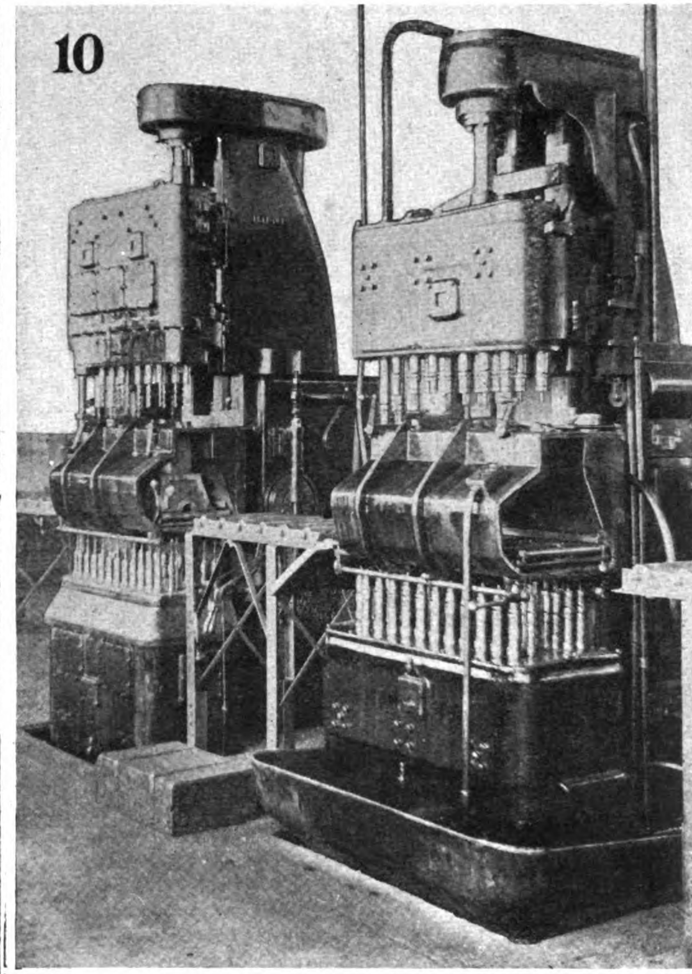
A LeBlond miller is used for milling the camshaft rear bearing pad. This operation is located from the locating holes and from the bottom surface. About ⅛ in. of metal is removed, the capacity of the machine being 62 per 10-hr. day. The block is then placed on a conveyor and starts through a battery of two No. 8 Defiance machines for cylinder boring. The first machine is a rough bore and the second a finish bore. The capacity of the outfit is 20 per hour, all six cylinders being bored at the same time. The location on this work, as on practically all of the following work, is from the locating holes and from the bottom face. On the rough bore the diameter of the cylinder is increased from 2 15/16 in. up to 3⅛ in., and on the finish cut the bore is increased from 3⅛ in. to 3 5/32 in. An interesting feature of the work on this battery of machines is that the conveyor extends over the table, allowing the block to be rolled directly into the machine. When a lever is pulled the conveyor drops below the supporting table level and the jig is clamped in place.

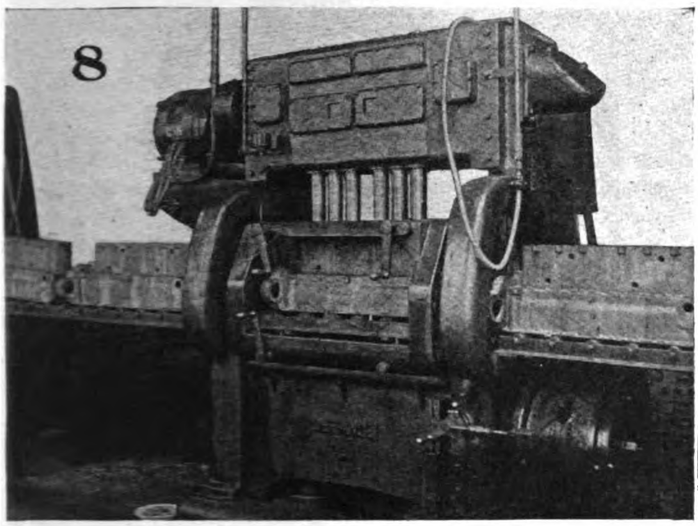
Chambered Cylinders

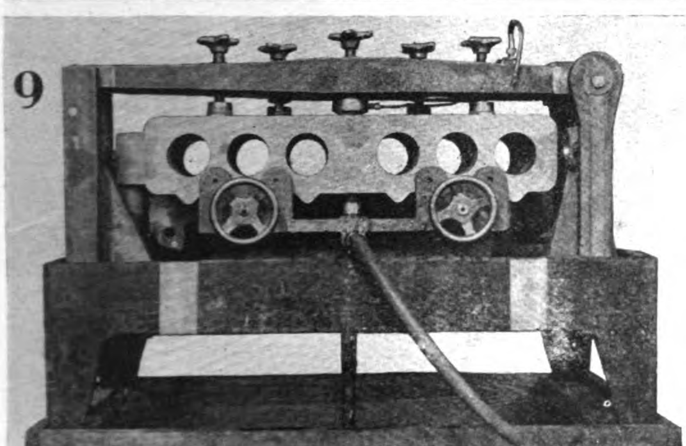
As the combined diameter of the two valves in the cylinders is larger than the cylinder bore, it is necessary to chamfer the cylinders for valve clearance at the top. This is done on a six-spindle Defiance machine, which takes this cut from the top of the cylinder. When this operation is complete the block is moved to a water testing jig for jacket leaks. The jig contains covers for the core holes and is so arranged that 45 lb. pressure can be put on the casting to check leakage.

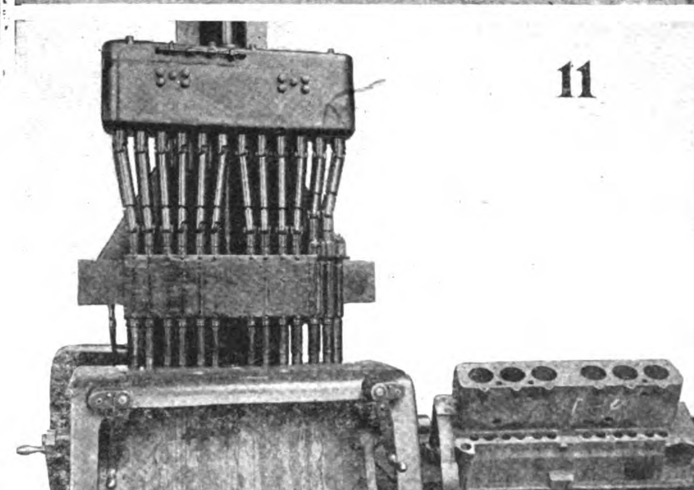
The next manufacturing operation is to mill the tappet boss, which is done on a Becker miller having a capacity of 45 per day. The location in this case is by the locating pads and the bottom face.



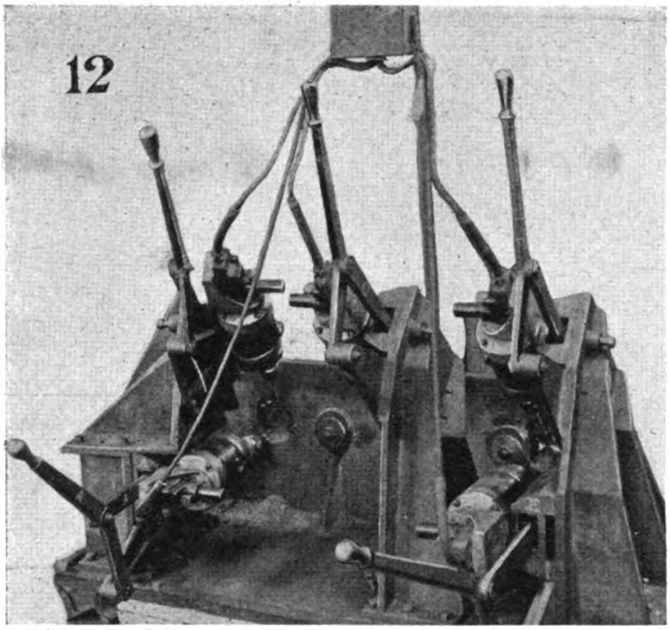


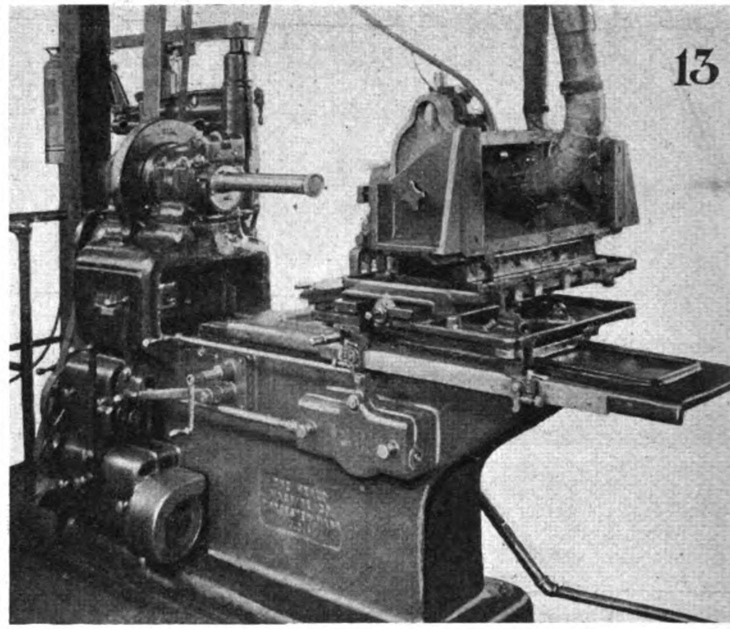


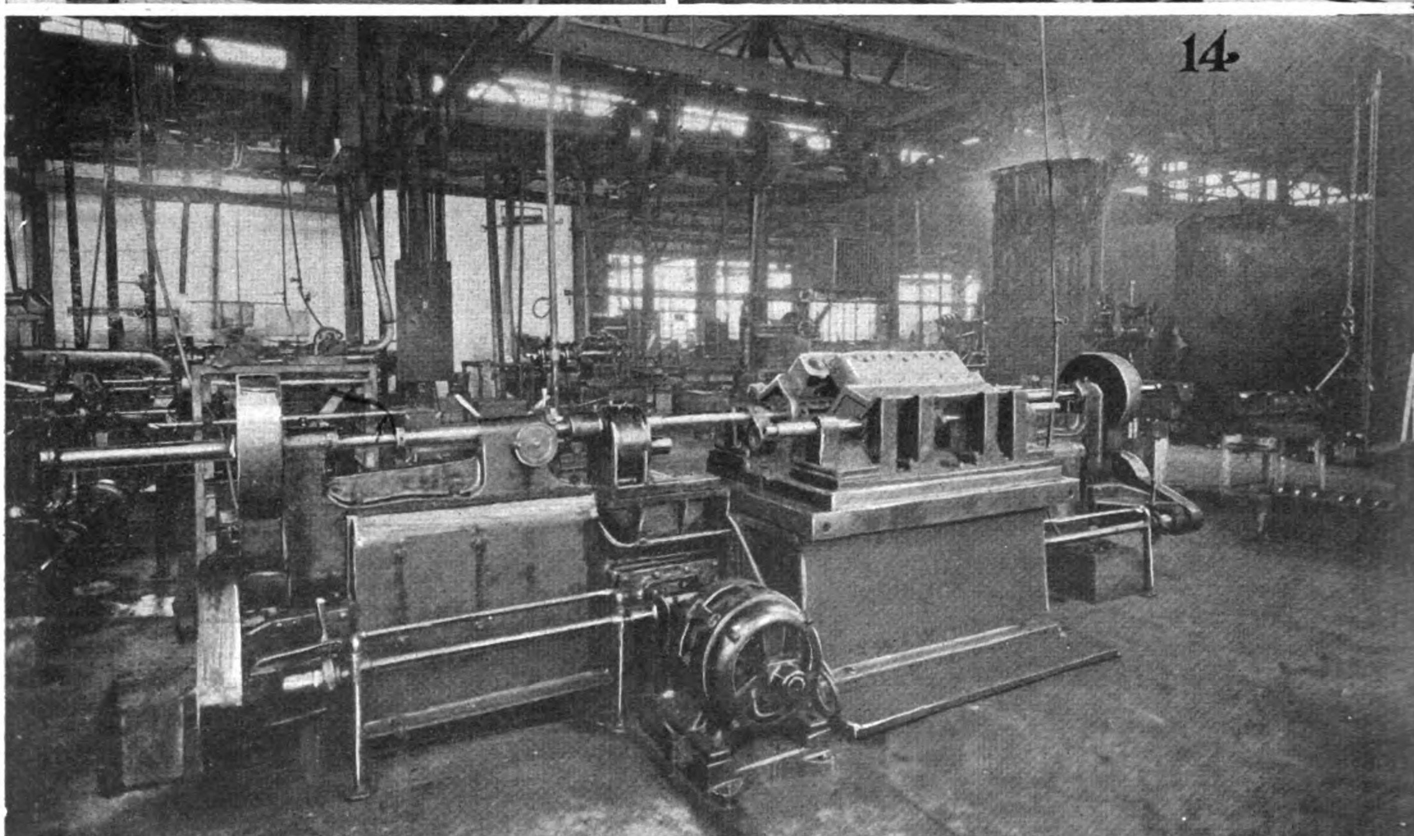




7—Rough cylinder boring machine operation. No block is shown in this machine so the jig construction may be illustrated. It will be noted that it is a tunnel jig with the roller conveyor in the jig so that the roller conveyor is continuous through the machine. The conveyor drops out of the way when the machine is in operation. 8—The finish boring machine. Only two boring operations are performed on this job. These two operations bring the barrels to grinding size. On this machine as well as on the rough boring machine will be seen an electric safety stop. The machines are directly driven and if the regular stop on the machine did not work the current to the motor would be shut off before damage could be done to the machine. 9—The water testing fixture. This operation comes after the finish bore and the fixture is clever, the arm across the top swinging upward, leaving the entire fixture open for the setting of the cylinder block. City pressure, which is about 54 lb., is used for this test and the block is left in the fixture for about 5 min. Two of these fixtures are used so that a man is setting a block in one while the pressure is on the other. Arrangements are being made to have this test made with hot water. 10—Defiance drilling and tapping machines which take care of the top and bottom holes at the same time. Another pair takes care of the horizontal holes in the same way. 11—Machine and fixture which drill the valve lifter guide holes in the side of the cylinder block. It will be noted that this drill carries 13 spindles, one of which is offset, being the extra spindle that drills the hole for the distributor. This is driven from the front end of the camshaft by means of a worm gear. Combination tools which ream as well as drill these holes are used on this machine







12—This shows a machine which is partially machine and partially fixture, designed and built in the Ansted shops. The oiling of the Ansted engine is accomplished under pressure and oil leads from the main bearings to the camshaft bearings are drilled in bosses, cast for that purpose. Five holes are required and all of them are at different angles. This fixture provides an electric drill for every hole set at its proper angle and a slide is provided. This entire tool cost $1,500, whereas to do this job on standard machines would have cost in the neighborhood of $12,000. 13—Grinding the cylinder. Note the exhaust suction pipe which removes grit directly from bore which is being ground. 14—Boring the main bearing and camshaft bearing holes. Rough caps are fitted to the main bearings during this operation so that the cutters get a full bearing. The fixture on this machine swivels so that one block is being set up and bars inserted while the other one is being machined. The camshaft bearings step down in size from the front. The main bearings step down in size from the rear. It is apparent, therefore, that in boring both of these lines at once they must be bored from opposite ends and the machine is therefore a double-end machine. The extra spindle shown in the left side of the machine is for a stud tool which bores and sizes a hole in the front gear housing, which is provided for magneto installation when necessary

One of the most interesting series of operations is that which now takes place. A group of four Defiance drilling and tapping machines is employed for this work. The first machine drills all of the top and bottom holes at the same time and is capable of easily taking care of 20 per hr., the capacity of the machine never having been reached in this plant. This would mean an excess of 200 per day, if desired. The second machine taps these same holes. The first two machines have 68 spindles each. The block is then moved to a second pair of machines which drills and taps the horizontal holes, taking care of both ends at the same time. These machines are equipped with electric stops which automatically kick off the motor should a spindle break or any other accident happen. The machines are operated by push buttons and stop automatically after the work is completed. The location of the work in these machines is by the locating holes and the bottom face of the casting.

The valve tappet guide holes are drilled and reamed, twelve at a time, on a Defiance machine, which also has a thirteenth spindle for drilling and reaming the igniter driveshaft hole. The location for this work is the bottom face of the casting and by dowel pins in the two locating holes. The machine is capable of taking care of 135 pieces per 10-hr. day, the diameter of the holes being 1¼ in.

A number of minor drilling operations follow this work, these including the cleaning up of the water circulating and oil regulation holes, drilling and tapping the ignition drive flange holes, the valve guide dowel screw holes, oil feed holes, etc. American radials are used for this work. The control rod holes are drilled on a gang radial drill, the holes being drilled in from both sides. This machine also bores the oil pump retainer flange hole and the retaining screw holes. A box jig is used for this work, the location being from the two locating holes and the bottom surface of the casting.

The next operation is to counterbore the core holes for Welch plugs, after which the spark plug holes are drilled, counterbored and tapped. This work is done on an Avey drill, the work being carried along on a jig which travels on a track below the three spindle drill, the three spindles, of course, being for drilling, counterboring and tapping.

The main bearings are bored on a Rockford horizontal drill with two bars operating at the same time. These roughbore the camshaft and crankshaft bearings simultaneously, the bearings being stepped for tool clearance. This operation is a roughing cut, the machine being capable of 40 per day. The finish cut is also made on a Rockford machine, this being a double ended unit which flycuts the crankshaft and camshaft bearings simultaneously. This machine is capable of 4 per hr., or 40 per 10-hr. day. The camshaft and crankshaft bearings are cut in from opposite directions, which allows the largest crankshaft bearings to be at the flywheel and the largest camshaft bearing to be at the timing gear end, as required by best engineering practice.

An ingenious layout is used for drilling the oil holes. These run in various directions, not square to either face of the casting, and are handled by independent electric drills. These are of Van Dorn manufacture and are arranged in a battery of five on a single jig.

The finish cut on the bearing for both crankshaft and the camshaft is taken care of by hand reaming at the present time. Eventually, air-driven Kelly reamers are to be installed. This operation takes a very light cut from the metal, the bearing being practically finished by the flycutting operation on the Rockford drill previously mentioned. Following this, the bottom of the cylinders are chamfered on a Baker Bros. milling machine, the oil gage and suction line holes are drilled and tapped on a Barnes drill and the magneto opening cover plate holes are drilled and tapped on an American radial. The magneto installation, of course, is only used on the export cars.

On a Binsse Machine Co. horizontal miller adapted particularly to this work, the rear crankshaft oil thrower ring groove is cut and the bearings are milled off to proper length. This machine operates with a cross feed, the blocks being fed up to the cutter.

The cylinder blocks are then washed in a Blakeslee washing machine, being washed with Oakite solution. They are air dried in an oven and sprayed with a primer, baked and then enameled and baked again. The cylinders are then ready for grinding, the grinding being the final operation, so that the heat of the drying oven for baking the enamel will not distort the castings after grinding. The grinding is done on No. 60 Heald grinders with Norton 303S wheels. From .010 to .015 in. of metal is taken off, the limitations on the work being plus or minus .00025 in. Exhaust fans are placed over the open end of the cylinder upon which grinding is taking place to exhaust the grinding dust immediately.

Sequence of Operations in the Manufacture of the Ansted Cylinder Block

Chip snags
Snag grind
Sand blast
Chip, remove wires, blow out with air and paint
Inspect sand holes, etc.
Mill locating pad in water manifold
Mill face front, main and camshaft bearing
Rough mill top and bottom (Davis)
Mill top, bottom and oil pump pad (Ingersoll)
Drill and ream two ½ in. locating holes
Mill rear camshaft bearing
Mill both ends
Rough bore cylinder barrels
Finish bore cylinder barrels
Inspect all preceding operations
Water test
Mill valve lifter guide flange and mill oil regulator pad
Drill and holes top and bottom
Tap all holes top and bottom
Drill all holes, both ends
Tap all holes, both ends
Drill and ream valve guide and timer holes
Drill 12 water circulation holes
Drill ½ in. oil relief holes
Drill one 23/64 in. hole
Drill two 17/64 in. holes
Tap two 5/16-4 in. holes
Tap two ⅜-24 in. holes
Countersink all tapped holes
Ream .375 holes
Drill, ream and tap all holes on both sides of block except core hole
Countersink and tap six 5/16 by 24 holes, bore and counterbore for plugs
Drill, counterbore and tap for spark plugs
Assemble rough cap for main bearing
Inspect all operations up to and including water test
Bore and ream crankshaft and camshaft brgs. and spot face magneto locating bearing
Dis-assemble
Drive five oil holes in main bearing
Drill one 7/16 in. and one 21/64 in. hole and counterdrill 9/16 in. hole
Tap ½-20 in. and tap one ⅝-18 in. hole
Drill and tap guide lock screw holes
Drill and tap timer bracket holes
Drill and tap oil lead holes over rear brg.
Drill three magneto pad holes
Tap two ⅜-24 holes and ream one 11/32 in. hole
Hand ream push rod guide holes
Chamfer bottom of barrels
Countersink all tapped holes and retap
Drill and tap ⅛ in. compression test cup holes
Mill combustion chambers
Straddle face main brgs. and cut oil slinger slot
Wash and put in Hubbard plugs
Grind barrels

Refinements in Chassis Construction

(Continued from page 60)

case of the front end of the chassis they furnish additional protection against collision, particularly protecting the radiator against the minor collisions which are constantly occurring in the congested parking centers. Cole uses a heavy tube at the front end of the chassis and Templar at both ends. An interesting chassis stiffener is the large flat plate at the rear end of the Stearns. This extends across the entire rear end of the chassis and beside providing a stiffening member acts as a foundation for the rear tire carrier.

One of the greatest lines of improvement in the chassis is the incorporation of anti-rattle features in the brake mechanism and in the shackles. In the brake linkage there has been a noticeable growth in the use of tension springs which keeps the linkage continually taut so that there is no chance of rattle. On the Oakland cars these little coil springs are very ingeniously mounted under the cross member which supports the brake equalizer shaft. The springs are smaller and more compact than usually employed for this work and are hung upon retainers which are free to rock in the cross member.

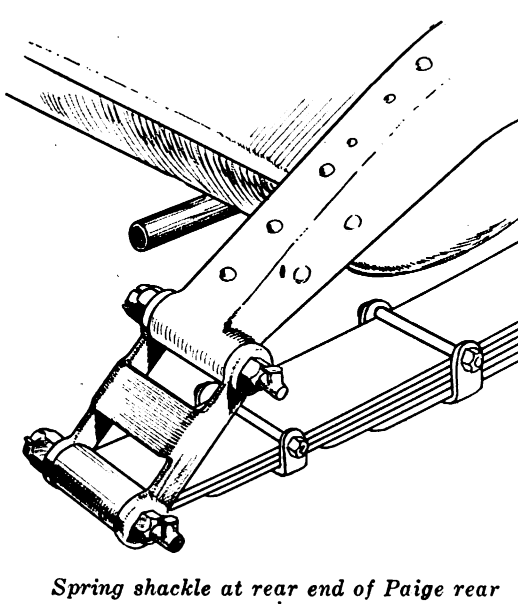
In preventing rattle in the shackles, which are notably the worst offenders in this respect, the use of the adjustable shackle on the Locomobile and on the new Navarre, designed by A. C. Schulz, formerly of Locomobile, are of interest. These have a take up secured by a clamp, which permits of compensation for wear. On the Navarre the spring is allowed to center itself on the bolt and then the bolt retainer is brought against a washer which is forced against the spring. Since the spring is allowed to center itself before the bushing is screwed against it, it is not necessary to hold the spring width to close limits in manufacture. The adjustment is held tight by a clamp bolt, the end of the frame horn being split.

From the standpoint of spring suspension the only radical developments apparent are the Roamer double cantilever, which is already familiar to most of our readers, and in the only German product shown. This is the Sauer on exhibit at the Commodore. It has a cantilever pivoted at the center with a rocking seat on the rear axle very similar to the Rolls-Royce suspension. In the Roamer installation the noteworthy point is that the cantilever arrangement is used in conjunction with Hotchkiss drive. The springs are super-imposed, one member being supported at the bottom of the brake drum, pivoted and anchored on the chassis by a forging and the other member being similarly mounted by a pivot point at the top of the brake drum and anchored at a point on the chassis ahead of the center on the lower member. The bottom unit is intended to check shocks and the top to check rebound.

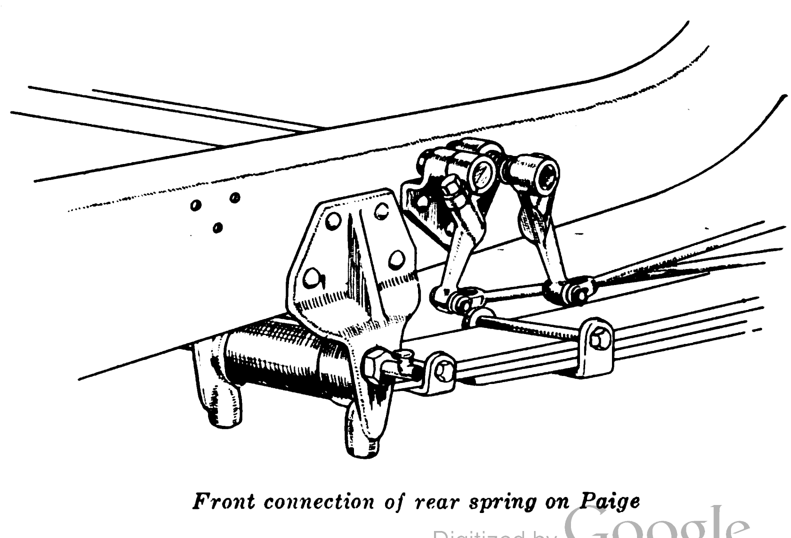
There are a number of variations in practice in the supporting of the rear end of the rear semi-elliptic spring. Where the frame has tapering side members, many designers are making an effort to take the twist out of the spring by keeping the spring itself parallel to the center line of the car. The use of a prominent drop in the rear end of the frame to coincide with the flatter spring suspension is quite a prominent feature and a few makers are sweeping the horn down for the purpose of dropping the side rails slightly, making the rear shackles tension instead of compression members.

Throughout the entire line of exhibits there has been a notable effort to increase the stiffness of the frame through the use of deeper side rails, by a greater number of cross members and by more thorough gusseting. There are a great many frames which taper materially in depth. For instance, the Scripps Booth, which is very noticeable in this respect, the depth of the frame being constant for only a short portion of the length. The Maxwell is another example in which the frame tapers considerably in depth. The majority of frames, however, have only slight taper and this takes place at the extremities. The bottleneck type has about disappeared and in its place the tapered frame is used to get the narrow front end necessary to give narrow turning radius and a sightly front end.

There are not any noticeable steering developments except perhaps in the lubrication of the parts where practice has been improved in line with what has already been said under the head of chassis lubrication. There is, however, a tendency on the part of a great many to use heavier oversize parts. The Hupp has been materially strengthened in this respect, the steering gear having been entirely revised and a larger unit installed.



Spring shackle at rear end of Paige rear spring



Front connection of rear spring on Paige

Clutches, Transmissions and Universal Joints

By Herbert Chase

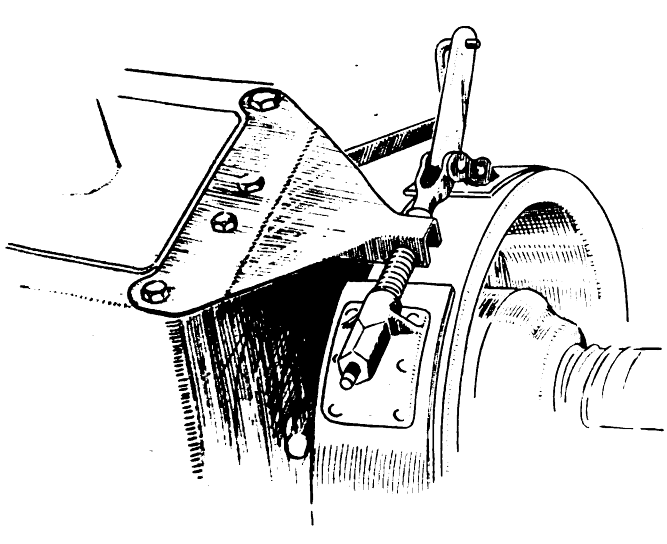
THERE is little that is really new in the way of clutches, although some makers have changed the type employed. Substantially all of the higher price cars use the multiple disk type running dry and faced with molded or woven asbestos composition. The new Pierce-Arrow chassis is fitted with this type, having finally abandoned the cone type, which was standard on chassis built by this company for many years. There are to-day in this country but few makers who continue to use the cone clutch and the tendency both here and abroad is toward the multiple or the single disk type which, as a rule, is smoother in engagement and less apt to cause clashing of gears when changing, because it does not continue to spin so long after disengagement. The plate or single disk type is very widely used in this country as it is also in Europe. It requires, however, the application of considerable pressure on the friction surfaces to prevent slipping, and this in turn means relatively rapid wear and a heavy pedal pressure unless a considerable multiplication by levers is employed, and even then the pedal pressures frequently used are excessive. This, indeed, is a point in which there is much room for improvement. In the case of cars driven by women, in particular, it is a serious mistake to use high pedal pressure, and it certainly does not add to the pleasure or comfort of any driver to be required to use unnecessary exertion to declutch the engine when changing gears.

There are several ways of overcoming this drawback. One is to use multiplying levers somewhere between clutch pedal and the disengaging member, as is done in several European and some American designs, Lincoln, Packard and Dorris being cases in point. Another is to use a larger number of disks with lighter springs, as is done on the LaFayette, or to employ some of the more recently developed materials which have a higher friction coefficient. A larger diameter of friction surface can also be used, but in this case means to stop spinning on disengagement are doubly important.

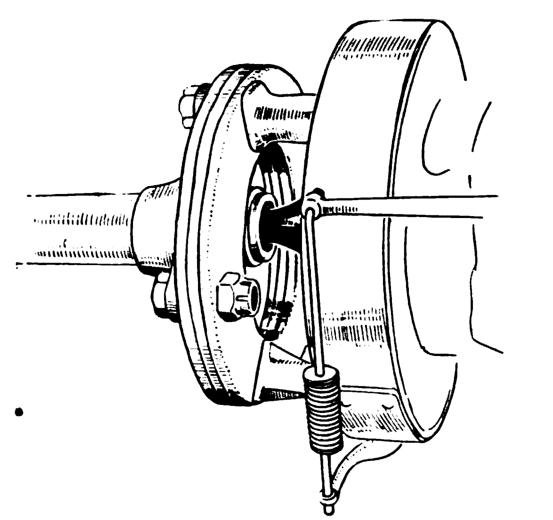
It is possible to design clutches that require no adjustment throughout the life of the facings, but most types in common use require occasional adjustment or other attention, hence it is desirable to make them as accessible as possible. This has been done on many cars exhibited, the Briscoe, Nash and Dort, for example, but many others are not easily accessible and in most cases it is necessary to remove the transmission when it becomes necessary to dismantle the clutch for refacing or major repairs. In some very recent designs it is not only necessary to remove the entire transmission in order to dismantle the clutch, but before this can be done the spring bolts must be removed and the entire rear axle be moved back! Inaccessibility is partly due in most cases to the use of a closed bellhousing. In other cases the bellhousing is open at the bottom, sometimes having a removable cover top and bottom as in the Cleveland. While the need for ready access to the clutch is not so important a factor as it used to be with the earlier cars, it should not be forgotten, even though the use of the unit powerplant has introduced a factor that has not simplified the problem of securing accessibility.

The clutch thrust bearing has in the past been a source of much trouble, hence it is pleasing to note a tendency to improve the design in this particular. Better and larger bearings are provided and the practice of using a forked throwout lever engaging with pins on the casing for the thrust bearing is being abandoned in many designs. When levers or cams with contact only on the forward face of the bearing casing are used the latter is free to rotate with the clutch, so that the bearing runs only when the clutch is disengaged, and not continuously as in the other type. Obviously the bearing will require less lubrication if it runs only when the clutch is disengaged. It can in this case be packed with enough grease to last for many thousand of miles, while in the other case it requires frequent lubrication, and a grease cup is often provided, this cup being placed above the floor boards in some cases, so that it will not be forgotten. In the Kissel car an oil lead was carried to a point near the rear engine cylinder where an oil cup was fitted, the idea apparently being to make it easy to oil the clutch bearing whenever valves or other parts under the hood are oiled.

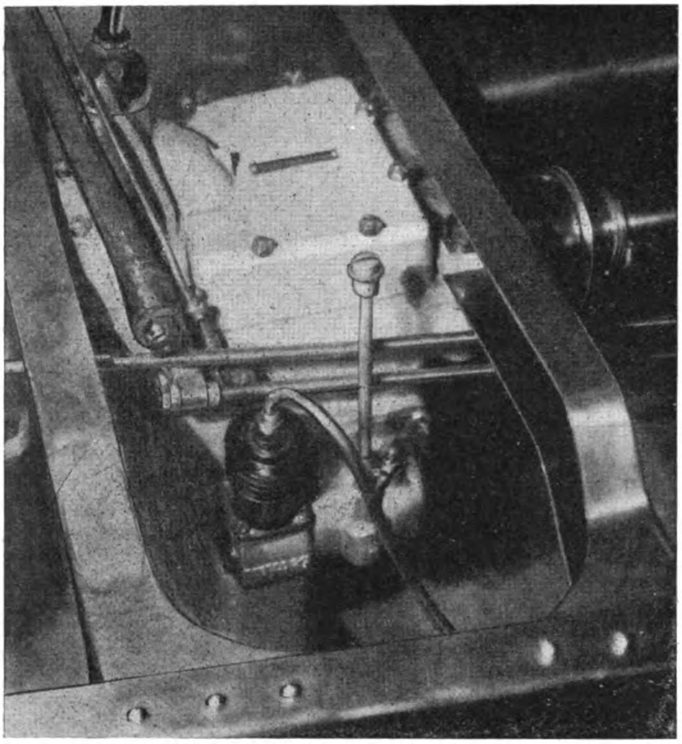
Apparently chassis designers are mostly men with medium length legs, otherwise more frequent arrangement would be made for adjusting the pedals to accommodate



Transmission brake support on Nash



Central guide for fabric universal joint on Briscoe



Air pump mounting on Pierce-Arrow transmission

the short or long legged driver. This is a very simple thing to do and is done on many cars. The practice might well be followed by all. A detail which most makers overlook is provided in a few cars, that is the fitting or rubber covers on the pedals, as on Pierce, National and LaFayette, among others. Serious accidents have been known to occur as a result of an operator's foot slipping off the clutch or brake pedals in a tight place or when instant action was required. This possibility is minimized by the use of rubber covers. Pedals so covered are also easier on the feet and help to prevent the feet from becoming chilled in cold weather. They should be more generally used.

Transmission

Novelties in transmissions are very few indeed. It is getting to be well nigh universal practice to rigidly connect engine and transmission, forming a unit powerplant by the use of a bellhousing, which encloses flywheel and clutch. This construction renders the use of flexible connection between clutch and transmission unnecessary, and departures from it involve expense which make the practice of fitting the transmission amidships almost prohibitive except in the higher priced cars, and even the newer higher priced jobs, such as Lincoln and LaFayette and Fergus, make use of the unit construction. Thus the transmission is usually supported from the engine, its weight being carried by the rear engine arms or a cross member of the frame bolted to the crankcase just forward or just aft of the flywheel. The overhang is frequently considerable, but the conical bellhousing and boxlike section of the transmission case provide the necessary rigidity, especially when the double universal joint construction is employed, as it so frequently is.

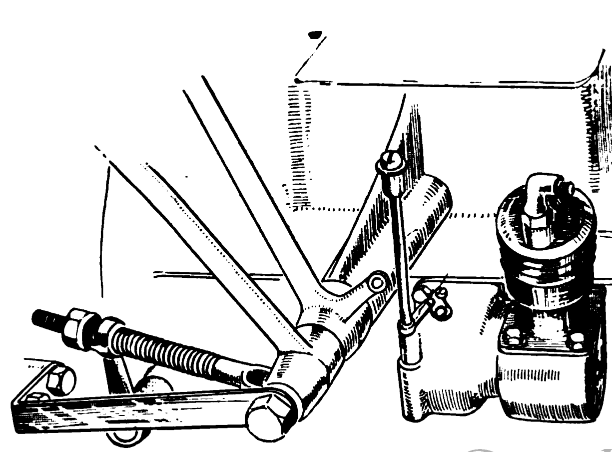
The use of three-speed gear boxes is more nearly universal than the unit powerplant. Three speeds are used in the new Pierce-Arrow, Packard, LaFayette and Lincoln chassis, but the Mercer uses a four-speed box. No one has attempted to emulate the British and Continental manufacturers in producing a light chassis with small size highly efficient engine and four-speed gearset, though such a procedure would seem to be called for if the fuel stringency so long promised becomes a reality.

The Fiat has a novel gear shifting mechanism. The shifter forks are carried on a cross shaft which is moved axially by side motion of the shifter lever. The change of gear is then made by rocking the cross shaft through motion of the hand lever forward or back in the gate. A single pair of links, one with ball and the other elongated socket ends imparts both lateral and rocking motion to the shifter shaft. Aside from this the changes noted in the design of the gearbox lie chiefly in the addition of appendages in the form of air pumps and propeller shaft brakes. Many of the latter are fitted, among them being Nash, Cleveland, Briscoe, Mercer and Citroen, and these for the most part are emergency brakes, a departure from the practice formerly employed of fitting the foot brake on the propeller shaft. Most of the transmission brakes are of the contracting type, the band being anchored to lugs fastened in sockets cast on the transmission case or to integrally cast extensions of the case. In the case of the Nash six, however, the brake anchorages are made from stampings bolted to the transmission case. In a few of the more expensive chassis, such as the Mercer, the transmission brake is of the expanding type, the drum having cooling ribs and the shoes being placed between the drum and the transmission. This makes it possible to use a camshaft running through or beside the gearbox parallel to the gear shafts and a neat linkage with a short pullrod connecting direct to the brake pedal, the brake in this case being the service instead of the emergency brake.

A considerable number, especially of the higher priced cars, among them Packard, Locomobile, LaFayette, Pierce and Dorris, are fitted with gear driven air pumps. These are nearly always mounted on the left side of the gear box and have but one cylinder. They are usually thrown into and out of engagement by turning a short vertical shaft which extends upward through the floor boards, or horizontally through the side member of the frame. Many makes of gear box are provided with S. A. E. standard opening to which the air pump can easily be connected by the purchaser if the manufacturer does not fit it as regular equipment.

It is almost universal practice to mount the gear shifting lever on a pedestal directly over the gear case. This makes a compact and neat arrangement which is sightly and provides a convenient means of bringing the control through the floor boards. The gate formerly used is no longer required and is used on only a few cars, Fiat and Stutz among the latter.

Holes through the floor boards are frequently made larger than necessary for the controls, thus admitting to the space above them noise, grease and cold air, which



Air pump mounting on Packard transmission

would be largely excluded if the space were closed by a flexible material or other means. A refinement in this direction would be especially appropriate when closed body is fitted.

On the whole, controls are more conveniently arranged than heretofore. Room for egress is usually provided, yet the gear shifting lever is so placed that it is easily reached by the operator. An offset lever is employed in many instances.

Speedometer drives are mostly from the transmission. Spur gears are frequently used for this purpose, but the neatest and best drive is the spiral gear, employed on Lincoln and some other chassis, for it is noiseless and can be made compact.

A commendable practice is that of fitting transmission locks as is done by Lincoln among others.

No marked advance in universal joint construction is noted, but improvements in detail, especially in lubrication means, are occasionally in evidence. In the LaFayette and Fiat chassis, for example, the single universal is lubricated by oil from the gearcase. One parts manufacturer (Merchant & Evans) is exhibiting a system of lubrication in which oil is forced through the universal joints and hollow propeller shaft to the rear axle, from which the lubricant is returned to a tank on the dash and again fed to the transmission. More hollow propeller shafts are being used, the solid ends being welded in place.

The metal joint predominates and is manufactured in a large variety of patterns, most of these being enclosed in metal or leather covers, but some are not enclosed and no adequate provision for lubrication made. Many makers employ flexible disk joints of fabric with rubber impregnation. Those used on the Briscoe chassis are held from radial displacement by the use of a centrally placed ball and socket. When a separate gearset is used the universal connection with the engine is generally of fabric, but Sauer, the only German chassis shown, uses a laminated metal disk for this connection.

The disk wheel is in great prominence among the special show cars. On the Franklin are the new Parker aluminum disk wheels which have been lately introduced and which, of course, have the quality of lightness to a marked degree, being about 15 lb. per set lighter than wood on this particular installation. Growing numbers of manufacturers are offering these wheels as optional equipment, the retail prices for this equipment averaging around $125 per set.

Passenger Car Bodies at the Show

By George J. Mercer

THE body display at the show this year is very interesting especially in the brighter color combinations, clean cut trimming designs (particularly in the finish on the edges) and the uniformly good looking tops on the open cars. There are an unusually large number of sport type touring cars and runabouts with cycle mudguards and steps in place of the runboards. These are generally fitted with disk or wire wheels and an increased number of cars have side wings on the windshield, and cowl lamps, in most cases attached to the base of the windshield itself. Nickel plating of radiators is more general and there is, altogether, a brightening up that cannot help but please the prospective buyer.

The keynote of the body display is the general refinement in detail. The models displayed include the conventional runabout, touring body, coupe and sedan, while the exhibitors of the more expensive cars show the two compartment closed body and a few town car types. Most exhibitors, however, seemed to have concentrated attention on the open cars in an effort to change the appearance or add new features.

The runabouts shown appear more substantial looking than in former years. There is no increase in the seating space, but the carrying space at the rear is larger. The runabout is essentially a two-passenger car and all attempts to take it out of this class have been abortive. These bodies have generous seating space, comfortable cushions and backs, and good height to the body side. The use of steps in place of runboards works out well on this type of car, as it gives the driver a near ground view when driving fast. The illustration of the top, Fig. 1, shows that even on this body type the tendency is to use the car with the top up. The use of the wings to the windshield are necessary when this top is used, as they help to prevent the wind pocketing under the top.

Two views of windshields are shown in Figs. 2 and 3, one portraying the side wings and the other a type used for protecting the tonneau. This latter is not commonly

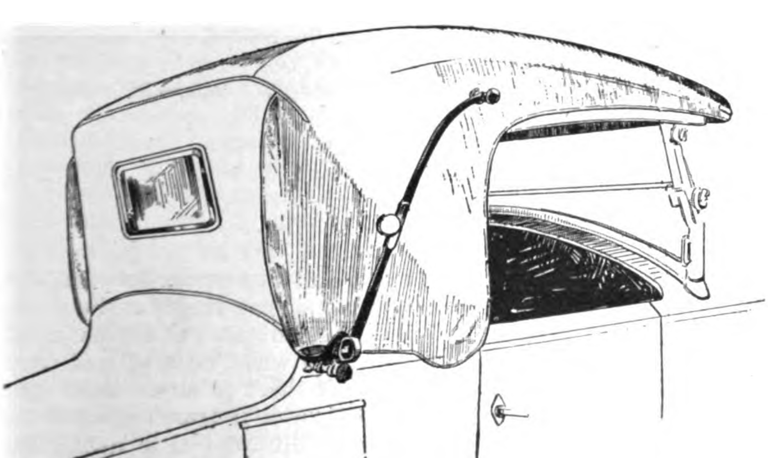


Fig. 1—Cole runabout with top raised

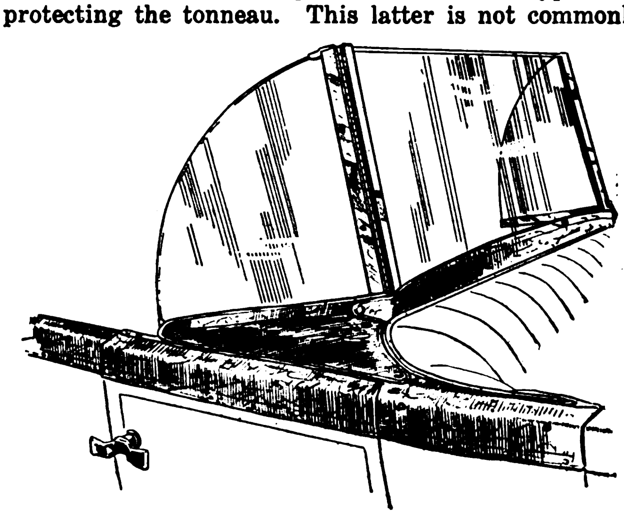

Fig. 2—Tonneau windshield of Roamer car

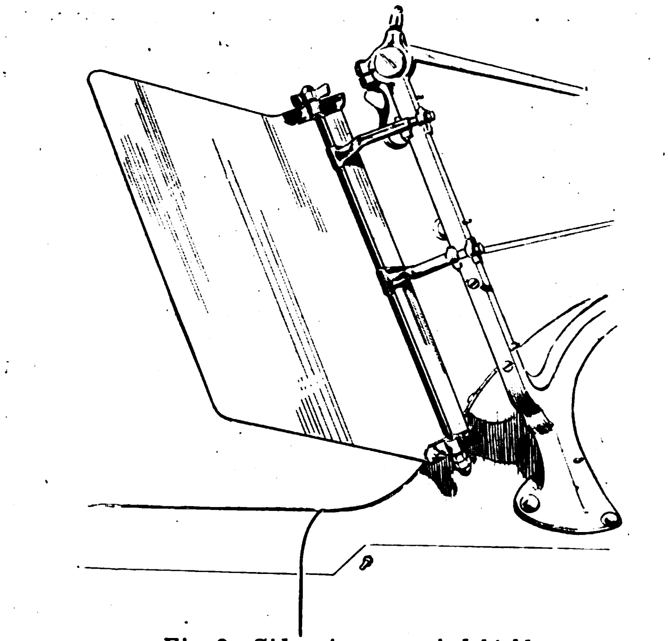

Fig. 3—Side wings on windshield

used. In this case the top of the body is protected by a leather skirt.

Windshield frames, like some of the other parts of the car, are being nickel plated. On some of the smart types of touring cars and runabouts, the nickel work included the radiators, windshield frames, lamps and door handles. The steps which often replace the runboards are cast in white metal and polished.

Fig. 4 shows a novel method of fastening the windshield to the body. It exemplifies the refinement in detail already referred to. Another part of the car that benefited by a change is the radiator. Addition of shutters has unquestionably improved the appearance of the front end of the car. The shutters are sometimes placed in a vertical position, but they are usually horizontal.

Refinement in open cars has been of a character that will be permanent. The brighter color combinations with striping will be more in evidence during the coming season than for many years past.

The buyer is attracted by the opportunity for individualism. He is often satisfied if this can be gained in the color scheme. There are no color combinations but there are more cars painted in colors and they are uniformly good. Workmanship and finish average better than usual. In general, the best colors were the blues, that is, the Rolls Royce or Belgian blue. The striping was usually white. Some of the wide stripes had hair lines at each side. When this is used in moderation the results are pleasing. There were cases in which the striping did not logically carry out any design pattern, but was continued from the flat over rounded surfaces. The tendency for some years past has been to eliminate striping on all except very high grade work, hence the art has, to some extent, been forgotten.

The disk wheel does not allow much latitude in the matter of colors. The very best results are obtained when the color used on the disk is lighter than the body color.

Some of the closed cars use bright color combinations with the upper part black, lake maroon, blue and gray being used to good effect in some cases.

Colored trimmings are less in use on open cars this year. There were isolated cases, but the majority used the conventional black leather for cushions, and imitation leather for the flat parts and on doors. On closed cars the trimming colors were modest and of inconspicuous pattern with very modest appointments.

Real comfort in the seating has made progress, but there is still room for improvement on many cars. The runabouts usually have comfortable seats, the height of the cushion in relation to the sides being generally low. The slope of the cushion and back are sufficient. Too many touring bodies lack this, and with the majority of five-passenger bodies there is an opportunity to give more room forward of the driver's seat. Seven-passenger body practice sometimes involving a cramped front section has in some instances been followed in the five-passenger model without logical reason. The cushion and back, when of the right angle or slope and height, together with correct height of body side as a retainer, will hold the passenger in without effort on his part when rough places in the road are encountered.

The tendency in design is toward more rounded surfaces, in contrast to the angular lines which have been the prevailing tendency for some time past. Production methods require as many units as possible to be interchangeable on several models, hence rounded radiators and hoods which blend readily with other rounded surfaces are in favor.

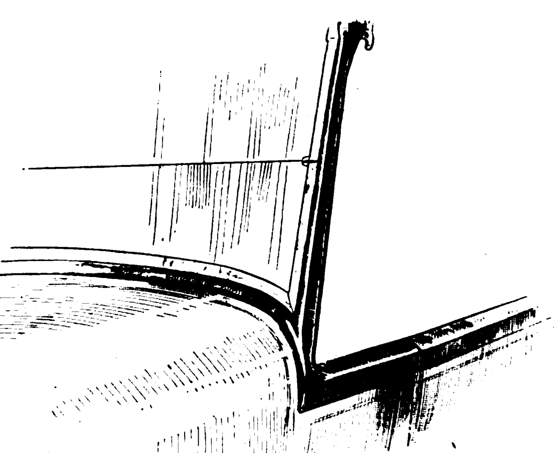

Fig. 4—Novel method of fastening windshield frame to body

New British Light Car

A SMALL air cooled car with friction drive has been placed on the British market and was exhibited at the recent London show. The engine is a two cylinder opposed, 3⅜ x 3 7-16 in., with steel, flanged cylinders and cast iron heads. The main feature is that the engine, rear axle and all of the transmission gear are carried on a sub-frame and are really built up as one unit. This unit is pivoted on a cross member of the frame at the front and attached by the springs at the rear. No universal joints are therefore required, nor is there any relative motion between the sprocket wheels of the chain, which can therefore be short.

The friction disk is mounted on an extension of the engine shaft, and the friction wheel on a splined cross shaft. At the end of this shaft there is an enclosed spur reduction gear, and thence the power is transmitted to the rear axle by a short chain. No differential is used. The wheelbase is 102 in., the tread 42 in. and the weight is approximately 900 lb.

Service Advertising Is the Need of Day

Largest meeting of Advertising Managers' Council of M. A. M. A. hears notable speakers who urge practical advice in all of their publicity. Start movement for revision of rules governing shows and exhibits.

By Clyde Jennings

AT no period of the well filled program that made for a busy day did the members of the Advertising Managers' Council of the Motor and Accessory Manufacturers' Association escape from the outspoken fact that advertising must be directed more and more toward the service work and that managers must examine more closely the objective and mediums of their advertising campaign. And let it be said, to the credit of the 150 or more men and two women present, that they showed no disposition to escape this service talk. Indeed, their heartiest applause was for the men who talked service most emphatically.

The service talk began at the very beginning. S. E. Baldwin, who called the meeting to order in the place of Chairman E. C. Tibbitts, spoke of the service of the Council to those who attended. Then E. W. Clark read a paper on "Selling the Automotive Industry to America." The speaker went into his subject exhaustively and traced the story of transportation from the beginning, showing how wealth had increased as transportation costs decreased. At this period, he said, we were at another turning point when railway building in this country was almost at a standstill, and that highway building is just beginning. The truck and the passenger car were coming into their own as utility vehicles. The excess of expectation and the purely pleasure use of these vehicles are undergoing adjustment. He advocated that when the spokesmen for the automotive vehicles appear before the Congressional Committee to seek the proper adjustment of taxes, that they openly advocate that automotive vehicles be taxed in proportion to their carrying capacity on par with railroad locomotives and cars. Clark expressed a belief in the need for a greater automotive organization than yet existed, to co-ordinate the work of the present organizations and that on this organization should fall much of the promotion work.

Alfred Reeves, general manager of the National Automobile Chamber of Commerce, reviewed briefly the organization work within the industry and expressed the belief that co-ordination was rapidly being effected. He said that he believed that if any fault was to be found with the advertising of the past it was that the automobile had been over advertised. His thought was that the needs of the past justified the means used, but that now a turning point had come and that more utility advertising was needed. Service was the great need of the day and a part of the advertising of service was to provide the 120,000 mechanics needed for this branch of the industry. He suggested that each advertiser of any automotive product inject into his display space some bit of information regarding the advances of automotive transportation.

C. C. Parlin of the Curtis Publishing Co. reviewed the business situation with an especial reference to what he termed the "retarded sales." His view was that while this country was not now buying as freely as it might, that the greatest stagnation of business was due to the lack of willingness of retail merchants, especially the smaller merchants, to lose some money themselves. Merchants, he said, like every other human being, were entirely willing to see some other person lose money. As a consequence they had been permitting their shelf stocks to dwindle, awaiting the necessity of buying. That period was here, he said.

He viewed the automotive prospects as entirely hopeful. He predicted early sales, but not an avalanche of sales. He reviewed the ownership in homes of several high priced articles—in the community canvassed pianos were in 44 per cent of the homes, autos in 42 per cent and talking machines in 32 per cent. Since that survey was made in 1918, the purchases had been 24 per cent of autos, 22 per cent of talking machines and 4 per cent of pianos. The speaker made the point that pianos were not "advertised." His definition of advertising apparently was space in thirty leading magazines. But he made this point only as to purchases since 1918, ignoring the fact that pianos are well advertised locally and in business papers and had in the canvass a higher percentage of ownership than the nationally advertised articles he referred to.

In a humorously cynical address A. R. Kroh, who introduced himself as a farmer, advised that it was a necessity for every automotive man to advertise his vehicle or part of a vehicle to the farmers in the plainest possible service terms so that the farmer might improve his position and be able to continue raising enough food to keep on feeding the great percentage of people who are non-productive from a food viewpoint. His address was well received and carried home its lesson of the responsibility of advertisers to sell their goods definitely and truthfully.

In his paper on "Cashing In On This Year's Automobile Shows" W. E. Brewster took the position that the show put before the public the spirit of the industry and as long as the public will pay to see the annual exhibition it is the duty of all concerned to participate. He advised a closer check of the visitors, etc. In his discussion of this paper, A. H. Bartsch brought up the subject of revised exhibition rules and was offered much encouragement. As a result, a resolution was passed that the executive committee name a committee to take up with General Manager Heminway the subject of revising the rules for shows, a work that Heminway reported to be already under way, and he welcomed the assistance.

"My Best Advertising Bet for 1921" was a forum participated in by Ralph Leavenworth, Eben Griffiths, Joseph Jacobs and R. E. Mackenzie. Their suggestions were for closer co-operation with the salesmen, better co-ordination of business paper, magazine and mail advertising, better follow-ups and generally for injection of efficiency into the advertising business.

The time and place for holding the quarterly meeting in March was left to the executive committee. The January meeting was held in the college room of the Astor Hotel. The attendance was the largest since the council was formed. Chairman Tibbitts's absence was due to the very serious illness of Mrs. Tibbitts.

The New York Show

THE opening three days of the New York Automobile Show have given unmistakable evidences of a potential buying market and also indications of a disintegration of the buyers' strike. While attendance may not quite equal that of a year ago, it is highly encouraging and the percentage of visitors displaying a particular interest is perhaps higher than a year ago. It has been conspicuous that there has been a great amount of interest in high priced jobs and that the percentage of attendance of visitors in exhibit spaces of such cars is greater when compared with the visitors in the exhibits of low-priced cars than formerly. In other words, it might be inferred that the drop in attendance is more with that class looking for low priced jobs than in that class looking for high priced jobs. A natural inference is that the last few months have not taken the buyer of high priced cars out of the market due to any lack of money but that he has been awaiting the developments of the market and, perhaps like many others, has been holding off from buying as long as possible.

The growing conviction that the merchandise shelves of the retail industry of the country are very empty and that they must come into the market is having an echo in the indications of real buying that the show has already given. The great arrival of buyers of textiles from all parts of the country in New York during this week, is a further indication that the buying strike is gradually breaking down. These buyers were in New York City last July and they refused to buy. Some of them came during later months in the fall and they refused to buy. The heavy reductions in many lines of textile prices made on Dec. 31, 1920, are having their effect. There has to be heavy buying in the textile field. This is going to play its part in breaking up the buyers' strike in other lines. It is the entering of the thin edge of the wedge.

The New York Automobile Show has never been a strong retail show. Coming as it does in January, it is too far in advance of the spring season to warrant hasty deductions as to the effect on later buying. There is a greater tendency this year than in former years to conclude that business is not picking up due to few retail sales. In other years when we did not approach the show through a supercharged atmosphere of depression nobody expected much retail business and consequently were not disappointed if it did not come. The results of this year's shows should be interpreted rather through the spectacles of a year ago than through the spectacles of this year.

There is no question as to the interest in the engineering features by those who know motor cars best. The engineers present were quite anxious to see what was on display and the parts manufacturers were free to say that their engineering departments are busier than ever before. All of this indicates that the present design of cars is not to be regarded as by any means fixed. Fortunately, the cessation in production is not permitted to check development. It has in fact given an opportunity for improvements which could not have been made during a period of intensive production. Many improvements known to be in process are not yet exhibited. Next year's show will, for this reason, be apt to contain more that is really new than is to be seen at the current exhibit.

A Change in Brake Practice

IN the past when a transmission brake has been used on American cars it has generally been the pedal operated service brake, while the wheel brakes were the rarely used emergency brakes. The chief object in making the transmission brake the service brake obviously was to render brake operation less onerous to the driver, as the transmission brake requires much less effort to apply than does the ordinary rear wheel brake.

Recently, there has been a complete change in this practice, and the transmission brake is now generally made the emergency brake. This change can be justified on several grounds. The emergency brake is undoubtedly the one which should be used for making emergency stops, that is, quick stops required to avoid collisions or other accidents. Now, the transmission brake is always far more powerful than the

rear wheel brake and therefore far better adapted for making quick stops.

Under ordinary conditions it is not good for a car to be stopped very quickly, and with the rear wheel brakes, which require much more effort to apply, the careless driver is not so apt to misuse his brakes. Moreover, the transmission mechanism is not subjected to the braking strains when the brakes act directly on the rear wheels. Unnecessary strain on the driving members has been the chief argument against the transmission brake in the past, and if the brake is used only for rare emergency stops the objection loses much of its weight. On the other hand it seems to be the reasonable thing to ordinarily use the mild brake and only in case a quick stop is absolutely necessary to resort to the more powerful one. The wear of tires will certainly be much reduced if this plan is followed, as compared with the case when the transmission brake is constantly used.

Stock rear axles usually carry two sets of brakes, and this tends to prevent the adoption of transmission brakes on new cars. However, where the axles are specially designed for a new job there seems to be a decided tendency to adopt the transmission brake, as this obviates the need for the exposed contracting brake on the rear wheels which is hardly in keeping with the modern practice in motor car engineering of enclosing all working parts so they are fully protected from dust and dirt.

Aircraft Development in U. S. During 1920

A SURVEY of aircraft development during the past year does not show startling advances in this country, viewed from a civil or commercial angle. American built and designed aircraft have maintained a high standard of efficiency, however, according to a statement of the Manufacturers' Aircraft Association.

Production of airplanes has greatly decreased and a general contraction of the entire aeronautical industry has been evident during the latter part of 1920.

Several very definite reasons can be noted as cause for the lack of civil and commercial development in this country. Among the chief of these are:

1. Lack of aerial laws.
2. Lack of a sufficient number of properly equipped landing fields.
3. Need for a definitely outlined policy of Federal jurisdiction.

The most important of these lacking provisions is considered by the industry to be the last. It is believed that because no definite Federal policy has been pursued in regard to the advance of civil aviation, we are in our present position, inferior to England and several other nations in this particular respect.

The matter is gaining attention from legislators, however. This is indicated by the fact that the New York State Legislature considered State aircraft legislation, but finally adopted a resolution asking Congress to enact a Federal law before the various States passed conflicting legislation.

American pilots flying American machines, however, have achieved excellent individual performances both in the way of speed, consistency, endurance, and altitude.

The Engineer as a Partner in Business

IT is often said that the engineer is not a good business man. Some executives hold the view that engineers in general are narrow-minded specialists who are either incapable of or unwilling to be guided by factors which must dictate business policy. Certain it is that some engineers are so absorbed in abstract theory and its application, or in making changes in design to improve or bring up to date the product they have in hand, that the effect upon cost and time of production with consequent effect upon marketing, profits, etc., is overlooked.

This tendency is one of which we should not lose sight in this day of specialization. It has often reduced the engineer to a mere employee when, if he had taken a broader view, he would have become a partner in the business, as he properly should. The truly successful engineer is the one who fits himself into his environment—who serves wherever and in whatever way opportunity offers—not the one who rides his own particular hobby or follows the narrow gage single track of a specialty to the exclusion of broader activity.

The engineer must strive to put himself in the position of the executive who must make a business success of the venture. When he takes this broader view, and secures the confidence of the executive he should, and we believe will as a rule, be recognized as a true partner in business. This is but one reason for the plea that engineers who have not already seen the light to cut loose from old fashioned precedent and widen their horizon for their own benefit. We do not advocate departure from engineering ideals worthy of the name, but we do urge upon the engineer the necessity of appreciating the viewpoint of the man who must make the venture pay, lest the whole structure fall, realizing, of course, that no structure can prove permanently effective which is not built on sound engineering principles.

On the other hand, it should not be forgotten that modern business is itself carried forward on engineering principles and that many of the most successful engineers are holding prominent executive positions in which their engineering ability is being utilized to the best possible advantage. Such men as C. F. Kettering, W. H. Van Dervoort, H. E. Coffin, H. M. Leland, H. W. Alden, A. L. Riker, Howard Marmon, K. W. Zimmerschied, J. G. Vincent and many others of like standing have reached positions which indicate that the engineer is not lacking in business ability. Similar success will attend many more engineers in the future if a broader conception of the function of the engineer becomes more prevalent.

Show Illustrates Trade Conditions

Public Not Deterred by Price Situation

No Likelihood of General Revisions—Production Schedules in Formation Stage

PRICE REVISIONS AND PRICES ON NEW MODELS IN EFFECT AT NEW YORK SHOW

REDUCTIONS

Peerless	4-pass. $3230 to $2990; roadsters $3200 to $2990.
Jackson	$200 on all models except new 4-pass.
Auburn	$200 on all models.
Davis	$200 to $290 on open cars; $390 on enclosed.

INCREASES

Franklin	$100 on open cars, Jan. 1; $100 on enclosed cars, Jan. 15.
Dort	$130 on new touring and roadster models.
Velie	$325 on new model 48 Sedan at once; $100 on new model 34 Touring, Feb. 15.
Moon	$200, Model 6-68, $2685; 6-48, $2185; enclosed, $3185. (Moon previously cut $400)

NEW MODELS

Saxon-Duplex	$1675 on open models; $2475 on enclosed. This represents a reduction of $220 on former open models, and $320 on former enclosed.
Columbia	5-pass. Touring, $1995; coupe, $2895.
Haynes	5-pass. Touring, $1985.
Mitchell	5-pass. Touring, $1995.
Malbohm	Coupe, $2395.
Detroit-Electric	Brougham, $4000.
Pilot	5-pass. touring $2285.

An increase of $200 was practically effected by Dorris through elimination of extra equipment, though refinements were added in construction.

NEW YORK, Jan. 10—Prospective purchasers of motor cars apparently are less interested in the subject of prices than they are in quality, workmanship and satisfactory service. Salesmen at the show are not often called upon to undergo heckling about how much their cars cost or what the prospects are for reductions. It is becoming apparent that with the general downward trend of prices for the commodities which make up the everyday budget, persons who own motor cars and who hope to own them will not be deterred from purchasing the car they want by a few dollars more or less.

As a matter of fact, factory representatives and dealers appear to be more interested in prices than do the public. The expectation had become more or less general in the trade that drastic changes downward would be announced at the opening of the show. This belief was not well founded. Quite a number of price changes were announced but there were fully as many which moved up as there were down. In cases where price schedules were raised, they generally were accompanied by new models or by refinements in the old models which made them more attractive and which justify the additional cost to the purchaser. Companies which guaranteed their prices are standing pat and in several cases the belief is expressed that the guarantees will be extended. In a few instances however, it is expected reductions will be announced when the guarantees expire.

Production 25 Per Cent

Except in a few instances, officers of manufacturing companies who are here for the show, make no attempt to gloss over the situation. They admit frankly that production at this time is virtually nil and that they are not being overwhelmed with orders. There are heard only a few glowing accounts of factories running in full blast and purchasers falling over each other to get cars. The average production in the industry at this time does not exceed 25 per cent and the chances are it is less than that. Fully a quarter of a million workers in passenger car plants are out of work. Most factories however, have resumed production on a much reduced scale or contemplate doing so in the near future.

In spite of the absence of actual orders, there is manifest everywhere a feeling of confidence in the future. This is not expressed in extravagant claims, but it shines through all the statements of present conditions. The sales manager of nearly every well known company is here, and they say frankly that business is slow at present but they are unanimous in the assertion that a greater willingness on the part of the public to purchase is reported by their dealers in nearly every section of the country. They are agreed that the buyers' strike is being broken gradually.

There is no expectation that there will be a big boom in business the first quarter of the year. As a matter of fact, most manufacturers will be well satisfied if they do as much business in the first half of 1921 as they did in the last six months of 1920. It is the general expectation that something like normal will be restored by April 1. All efforts to obtain tentative production schedules for the year are futile. Factories expect to be guided by the results of the New York show.

Production Matter of Sales

Production schedules in factories, large or small, whether located in the Detroit zone or out in the "sticks" depend entirely upon developments in the next few weeks, and to a considerable extent, on buying tendencies evinced at the show here. Not a factory representative at the New York exhibit could proclaim anything definite in the line of a schedule as the show opened.

Sales managers were a unit in the opinion that production for some time would be entirely on a sales basis. This was emphasized particularly in the higher priced cars.

Considerable apprehension was expressed of a too sudden development of business which would catch the factories unprepared to go into capacity production and which might cause another ascent in prices. With the results of the show here analyzed, however, the factory executives hope to be able to prepare themselves for early spring developments and meet business without undue delays in deliveries.

No Stocks in Salesrooms

Few dealers are stocked to any extent to meet a sudden spring onset of business, the factory men declared, this condition being particularly acute in the Middle West and agricultural districts of the country where credits required to carry winter stocks had been withdrawn with the agricultural and transportation crisis of the past summer.

This condition, sales heads were agreed, is likely to bring upon the factories the necessity of getting six months normal production rushed through in three months. To forestall this, the developments of the show and the general attitude of the public will be scrutinized

(*Continued on page* 90)

Enthusiasm Kills Sales Resistance

Distributers Place Contracts for Cars

Evidences of Good Retail Business Also Seen to Keep Production Even

NEW YORK, Jan. 12—Assuming for the sake of argument that all factory sales managers are prevaricators and discounting their statements by half, the tide has turned in the passenger car field and the sales resistance offered by the public is slowly but surely crumbling.

The New York show is bringing business not only at retail but from dealers and distributers. There is substantial e idence that dealers are placing orders without strings on them and fixing shipping dates. One surprising feature of the exposition is the large number of dealers and distributers who are sticking close to the exhibits of their chosen line and thereby feeling the public pulse.

As the show has progressed, uncertainty has given way to hope and hope to confidence. The faces of men in all branches of the industry who have gathered here in large numbers from all parts of the country are wreathed in smiles. When they started to New York they seemed more or less dubious as to what the actual results of the show would be but when they saw the crowd on the opening day, they became hopeful and as the throngs around the exhibits have steadily increased in size, they have become confident.

Confidence Becomes General

The feeling of confidence is shared not only by passenger car manufacturers, but by parts makers, tire manufacturers, distributers, dealers and salesmen. The people attending the show are not idle curiosity seekers, but a large proportion of them actually intend to buy cars. This is evidenced by the careful way in which they do their shopping and by the intelligent questions they ask. It is apparent that the manufacturers of expensive and medium priced cars will do fully as good a business in proportion to their normal production as those who make the lower priced vehicles.

Factory sales managers and their assistants are not sitting in easy chairs in hotel rooms waiting for dealers to call upon them, unless it is to keep appointments, but are working with the salesmen at the exposition. The statements they make are not roseate and they do not appear to be exaggerated. There is no attempt to give the impression that factories will be running full blast in a few weeks, but it is plain the men who sell the factory output are greatly encouraged over the outlook.

They are unanimous in the assertion that the business which the show is bringing is much better than they anticipated. They refuse to make predictions as to production schedules for 1921 and they do not expect the business for the year to equal that of 1920, but they are confident the year will bring a normal trade.

No More Overproduction

It is safe to say that from now on there will be no over-production of passenger cars. Factory heads are determined to produce only enough to meet the actual needs of dealers and there is no intention of renting warehouses to store cars for which there is no immediate demand. One company reports that it already has on hand orders for approximately 15 per cent of the cars it expects to make this year.

All the sales managers say the majority of their dealers have ceased to shake their heads in discouragement and that they are vastly more hopeful about a satisfactory spring business than they were even a fortnight ago. The New York show has proved its value and it probably is doing more to aid the industry than any exposition previously held.

MILES SMILES

S. A. Miles, veteran manager of the N. A. C. C. shows, is chuckling over the success which is attending the New York exposition this year. He was confident that there would be a satisfactory attendance but the interest on the part of the public has exceeded his expectations and he believes a substantial number of actual sales will result from the show.

Southern Reserve Sees Improvements in Outlook

ATLANTA, Jan. 10—Reports received by the Federal Reserve Bank of Atlanta from various parts of the sixth district, which comprises nearly all of the Southeastern area, indicate an improved outlook for the beginning of the new year, and portend a return to normalcy, in the opinion of M. B. Wellborn, governor of the bank. Business and industry in general throughout the Southeast is beginning to resume activity, Wellborn stated.

He further stated that he believed business was becoming gradually more stable and that the outlook for the future indicated a return to normal during the next few months.

Factory Executives Assume Active Roles

Many in Attendance at Opening of Show to Push Business—Service Men Active

NEW YORK, Jan. 10—Seldom have there been so many factory representatives at a show as are here this year, especially for the opening. It is significant of the trend in the industry that several service managers have stationed themselves at the exhibits of their companies to answer questions and see that nothing goes wrong with the cars displayed. Engineering departments also are well represented. The salesmen on duty are in most instances under the watchful eyes of factory sales managers. This is a business show and the men from the factories are sticking on the job. They have come for work and not for amusement. Here are some of the factory representatives who arrived for the opening of the show:

Hupmobile—Charles D. Hastings, president; O. C. Hutchinson, general sales manager; Frederick Dickinson, advertising manager; C. E. Salisbury, service manager.

Cole—President J. J. Cole; H. R. Hyman, advertising manager.

Nordyke-Marmon—President W. C. Marmon; H. C. Marmon, vice-president; F. E. Moskovics, vice-president; H. H. Brooks, assistant sales manager, A. J. Rogers, advertising manager.

Jordan—President E. S. Jordan; R. S. Begg, chief engineer; Paul Zens, secretary; W. B. Riley, sales manager; S. R. Thomas, assistant chief engineer; J. H. Kelley, factory manager; R. A. O'Reilly, foreign sales manager.

Packard—President Alvan Macauley; J. G. Vincent, vice-president; R. E. Chamberlain, assistant general manager; H. T. Gardner, carriage sales manager.

Franklin—President H. H. Franklin; G. R. Taxada, engineering department.

Oldsmobile—President Edward Ver Linden; Leon R. German, vice-president; Charles A. Tucker, general sales manager; Guy A. Peasley, assistant sales manager; Thomas O'Brien, manager sales promotion; R. K. Jack, chief engineer.

Dort—President J. D. Dort; D. M. Averill, vice-president; John D. Mansfield, general sales manager; H. S. Daniels, advertising manager; F. A. Petrie, assistant sales manager.

Velie—F. E. Bradfield, vice-president and manager; H. T. Wheelock, advertising manager; L. E. McKie, sales representative.

Columbia—President J. G. Bayerline; A. T. O'Connor, secretary-treasurer; W. L. Daly, sales manager; Charles E. Pelton, supervisor of agencies; George C. Gurney, service manager; William C. Hunt, advertising manager.

Auburn—President M. Eckhart; A. P. Kemp, vice-president; J. I. Farley, sales manager; A. M. Graffis, chief engineer; A. R. Johnson, assistant sales manager.

Haynes—Gilbert U. Radoye, director of advertising and sales promotion.

Peerless—R. J. Schmunck, general sales manager; W. W. Lewis, assistant sales manager; C. Sterling Bailey, advertising manager; W. W. Mitchell, Southern representative.

Dorris—President G. P. Dorris.

(*Continued on page* 98)

LIVE NOTES OF INTEREST AT NEW YORK SHOW

TWO avenues of progress are open before the industry according to a merchandising expert who has studied it. First, he stated, there is need of greater capitalization. Too many factories, he declared are under-capitalized.

The second need, he asserted, is for real, active, studious, working sales managers who can do something besides write contracts and ship cars. He said we must revise the industry in this important point. He said a company which he represents is now looking for a $25,000 sales manager—and hasn't found him yet. And he added that men like Normal A. Hawkins and other eminent sales executives would be found back in key positions in big organizations inside of a few months.

The Holmes Automobile Co., Canton, Ohio, is producing five of its aircooled cars daily. It has cut the wages of its employees from 5 to 10 per cent. Prices are guaranteed until July 1.

The Kline Car Corp., Richmond, is at 60 per cent production. No reduction in wages has been made. Prices are guaranteed until June 1.

The Saxon company expects to announce its production schedules for the year by February 1. It is now making five cars a day. When the factory really gets into operation, it is probable a wage cut of 20 per cent will be made.

The plant of the Kentucky Wagon Mfg. Co. which makes the Dixie Flyer is practically closed and no wage cuts have been made as yet. Prices have been guaranteed to May 1.

The LaFayette factory at Indianapolis is said to be producing cars at the usual rate and no wage reductions have been made. The company has not guaranteed prices but expects to make no changes in the near future.

General Sales Manager J. W. Connor of Pilot said contracts had been signed by him for half of the anticipated output of 2500 cars for the year. The company is making a higher priced model than ever before, a five-passenger touring car, and is finding sales generally satisfactory. Slight wage cuts have been made and inefficient workmen weeded out. H. E. Walker has been added to the personnel as assistant sales manager.

MAKERS of the Stanley steam car expect to increase prices in the next few months unless reductions in parts prices and materials are made. These were contemplated when reductions were made recently in prices but as yet they have not been realized. Wages at the factory are to be reduced and the full force of employees kept working unless the employees decide upon a short work week at present wages.

Apperson factory representatives sensed a continuance of sales resistance until possibly April 1, and in the interval until then thought several manufacturers might be compelled to go out of business. Production at Apperson factory was strictly on a to-order basis and would not be increased until it was evident that sales resistance had been overcome. Wages were lower, they said.

General Sales Manager T. L. Marshall of Stutz said his company would be in a position to outline production after the New York show. The show should be a big factor, he said, in showing just how much sales resistance had lessened. Wages at the Stutz factory, and in fact in all Indianapolis factories, was practically on the same level as formerly, the companies having found it impossible to maintain efficiency of workmen at lessened wage.

Cadillac swung into production Monday, but no information could be secured as to the production schedule or the number of men employed. Prior to the shutdown for the holidays, Cadillac was building on a schedule of around 2000 cars a month with a force of more than 2000. It is known, however, that Cadillac had a large surplus, and unofficially it is stated production will be held down to about 25 cars a day for the time being.

Packard still is operating about 50 per cent of its force with a production schedule around 25 daily, chiefly the new single Six.

MANUFACTURERS of enclosed bodies, say their business has suffered because of the open winter. In one cold week one company sold 50 bodies and the next week when the weather was mild again, practically none was sold. As a result of this condition, dealers are cutting prices to unload their stock.

Locomobile and Mercer, the Hare's Motors cars, are being produced only on a sales basis. Wages are at the same level but factory efficiency has been increased. No price revisions are under consideration.

Sayers & Scoville Co., maker of the Sayers car, finds its production fairly stable owing to its specialization in cars for commercial purposes, such as motorized funeral equipment, ambulances and work requiring special bodies. Demand for this work is setting in very strong in New England and the East generally. Wages are on practically the same level as previously to maintain efficiency. No hesitancy would be exhibited by the company in increasing prices, General Manager Hess said, if it were thought necessary to maintain standards.

The Oakland distributers in New York report the best pre-show week business in their history. Prior to that time, sales were practically dead.

The Cole company expects its business for the first half of 1921 to equal the last half of 1920 and that the second six months of this year will be still better. Shipments are being made only to fill actual orders. Prices have been guaranteed to April 1. No action has been taken as yet on wage reduction.

The Nordyke-Marmon Co. is operating on a 25 per cent production basis. No price changes have been made and nothing has been done in cutting wages. H. H. Rice, sales manager, will return this week from a six weeks tour of Europe where he has been establishing agencies.

ORDERS in the past ten days have brightened appreciably, representatives of most factories declared, many coming in the nature of surprises. A new dealer signed by the American in the Minneapolis district has ordered a car-load shipment for immediate delivery when no orders had been expected from him before spring.

The Jordan company is producing at the rate of 35 per cent of normal. Business in December was better than either in November or October and a further increase is expected this month. Slight wage reductions have been made in the factory.

A reduction of 10 per cent has been made in wages paid employees in the Maxwell service stations in the Metropolitan district.

The Dorris Co. expects this year to equal its 1920 production. No wage reduction has been made in the factory because it is the purpose of the company to use only the highest class workmen in producing its cars The price of the car has been guaranteed and there has been an increase of practically $200 in the price to the consumer by the elimination of spare parts in the standard equipment although this has been invested by the company in superior materials.

The McFarlan Motor Co. is said to be in full production. Prices have been guaranteed to May 1. There has been no readjustment as yet in factory wage scale.

The estimated production of the Hatfield car for 1921 is from 500 to 600. The factory now is closed.

Production of the Pan-American car at present is at low ebb, but more orders are being received. Wages have been reduced from 10 to 20 per cent. Prices have been guaranteed to July 1.

The price guarantee on Noma cars probably will be extended from March 1 to July 1. Production this year is expected to reach 300. An average reduction of 10 cents an hour in wages has been made in the factory.

CHARLES A. VERLIN, eastern representative of the Hanson company, said its record of price maintenance without change for six years will not be sullied now. Sufficient material is on hand to make 1500 cars, he said. Though production is now only at the rate of four or five a day to meet sales, this could be increased immediately to capacity.

Maxwell-Chalmers dealers have been greatly cheered by an announcement that the reorganization plan which provides for a consolidation of the two companies has been declared effective and that details of the proposed new management probably will be announced in a few days.

PUBLIC INTEREST BRIGHTENS BUSINESS PROSPECT

W. E. Metzger, vice-president of Columbia Motors and a director of the National Automobile Chamber of Commerce, reports there has been a very marked improvement in the feeling of Detroit manufacturers in the past fortnight. They expect a steady increase in business from now on, but they have no idea that the upward trend will be rapid. In Metzger's opinion, the used car problem is one of the most serious which confronts the industry at this time, and he believes that all dealers would do well to follow the example of those in Detroit and clean out their used cars regardless of their losses, so that the decks can be cleared for new business.

The Oldsmobile plant is producing 35 cars a day. A reduced factory force is working at a nine hour schedule. Wages were reduced two weeks ago.

H. G. Wilson, Detroit distributer for the Auburn line, last week drove 25 cars away from the factory.

The new Navarre six cylinder model is on display at the show. Prices for it have not been announced yet.

WILLIAM SMALL CO., manufacturer of the Monroe, received orders for 18 cars last week from Indianapolis purchasers. The parts department of the company has been kept in continuous operation. The outlook for the future is so encouraging it is hoped that it will be possible to lift the receivership in the near future.

The Dort factory is practically dead in production at present because it is changing over from its old to its new models which are being shown here for the first time. It already has received a substantial number of orders for these cars and they will be placed on the market Jan. 20. When the factory gets into operation. wage readjustment will be made.

R. E. Olds, president of the Reo Motor Car Co.. is a sane optimist regarding the future. He feels that his company is producing cars at a rate as nearly normal as any passenger car concern, and he expects a steady improvement in business, although he does not look for any sudden jump. As a matter of fact, he believes a normal spring business will develop after the show, but he has no expectation that it will be abnormal as it was last spring, nor does he think the 1921 sales will be as large as those in 1920. His expectations regarding the future are based upon his own observations and the views of his distributers.

Pat Emerson, assistant sales manager of Reo. who is in charge of sales of the "speed wagon," says the world looks a lot better than it did two or three weeks ago. As proof of his assertion he tells of Henry Adams, his dealer at Fostoria, Ohio, who is driving 150 vehicles away from the factory this week. December, in his opinion, marked the darkest hours for the industry. The commercial vehicle end of the Reo business has been good all through the period of depression, however, and the factory is running full blast, giving employment to 5000 men. Emerson has sold cars right along but he says the secret of his success has been hard work and constant plugging with not enough hours in the day to do all he has wanted to accomplish.

HUPP Motor Car Corp., which has been on a schedule of 35 cars a day since Dec. 1, now is building 50 cars with a slight increase in the working force, and will continue that schedule throughout this month. Good reports on prospects are being received from Hupp dealers, justifying the 15 per day increase in the present production schedule. Hupp has about 800 men working.

The plant of the Elgin Motor Car Co. is running at about 65% of capacity, thanks to a very large export order given by Gaston, Williams & Wigmore. Its own export business is holding up remarkably well and representatives of the company at the show say that they have had many inquiries from exporters who ship cars to Sweden, Denmark, England and India.

The drill department of the Clark Equipment Co. is working full time, while every department is operating to some extent on a four-day a week basis. Taken altogether, the entire plant is working about one-half normal capacity, according to E. W. Clark, advertising manager of the concern.

Wages are controlled by the workmen and have not been reduced. Questioned as to whether a cut was likely, Clark said that future conditions would naturally govern, but expressed confidence that having raised wages in the plant, employees would reduce them again when conditions and necessity warranted a cut.

Continental Motors officials are meeting this afternoon to discuss production plans, and from the meeting information was given out that 2500 men would be put to work tomorrow in the Detroit plant.

Paige, which began taking on men last week preparatory to getting into production, had between 800 and 1000 men working, with a production schedule of 25 cars a day. Orders on the books and reports from dealers, according to production officials, justify announcement of a schedule increase of 10 cars a day next week, with a complete increase in working force, and two weeks from today the schedule will be increased to 45 a day.

DU PONT is making two and three cars a day at the new Moore, Pa., plant and is ready to go ahead at full speed as soon as conditions require. E. P. du Pont, president of the company, has taken the general managership of the company under his direction for the time being, A. M. Marris, former general manager, having resigned. Wages are lower than formerly and labor efficiency is at a high point.

Liberty Motor Car Co. will resume next Monday with several hundred on a schedule that will approximate around 375 cars a month. Liberty reports splendid information from the dealers' field in the last two weeks, and officials at the plant feel confident that the production schedule will be increased steadily until late spring, when it is believed the factory will be on a basis of pre-war normal conditions. Liberty, while the plant has not been down completely, practically has been producing no cars for some time, and the plant's resumption next Monday will permit of increased operations by the Motor Products Corp., Timken-Detroit Axle Co., the Michigan Stamping & Tool Co. and other parts makers affected by the Liberty recession.

Scripps-Booth is operating with about 250 men building closed cars, chiefly on a schedule of a bout 20 per cent of the normal conditions, or approximately 250 cars a month. This schedule will be increased to 25 per cent later this month, and by Feb. 1 it is hoped to have the factory running on a 50 per cent basis, with a full production schedule March 1. Scripps dealers, according to Pres. Sarver, feel that the bottom has been reached, and they are now moving upward with prospects for gradual steady improvement in demand. The actual orders on hand and the reports on prospects from dealers are the basis on which the present production schedules have been outlined, and orders to parts makers in line with the schedules fixed have been sent out.

Both Maxwell and Chalmers plants began building cars today on a schedule of 25 of each type of car in each plant daily. About 375 men are at work in the Maxwell-Chalmers plants. It is the plan of the officials to increase this schedule beginning Feb. 1.

STUDEBAKER opened its second unit in Detroit Monday simultaneously with the opening of the factory at South Bend. With full resumption today, Studebaker starts a schedule of 90 cars in South Bend and Detroit, about 1100 men returning to work at the Studebaker Detroit plants today, which added to the 400 who returned to work in plant 5 last Monday gives a force of 1500.

Oakland Motor Car Co., which had planned to reach a production of 100 cars a day, still is behind that schedule, according to W. H. Maston, assistant general manager, who declined to say exactly what the daily output is. He intimated, however, it was around 75 cars a day, and said the factory was employing about 33⅓ per cent of the regular working force. The present output, Maston said, would be maintained until the demand justified an increase.

Buick resumed production today and will build about 250 cars daily until the demand justifies an increase in the schedule.

Chevrolet, which resumed production last week, now is operating on a schedule of 100 a day.

Public Not Deterred by Price Situation

Absence of Stock Cars May Cause Heavy Spring Demand—Parts Reduced

(*Continued from page* 86)

closely in an attempt to meet the demand at all times with instant deliveries.

Manufacturers of essential parts here for the exposition, are somewhat perturbed over their inability to get estimates of car production schedules. They say that thus far manufacturers of complete vehicles have been unable to give them any idea of the number of cars they will purchase. For that reason the parts men have been unable to make contracts for supplies of raw materials. But they are hopeful of getting some figures which will be helpful within the next two or three weeks. They are agreed however, that the general tone of the market is better and say that some orders are being placed. Most of the parts factories which have been down have reopened on a much reduced schedule or are preparing to do so.

The downward trend of prices in the parts field is more marked than in the passenger car end and numerous reductions have been announced.

Of fifty-two representative accessory exhibitors, thirty-seven, including some of the larger companies, stated that they had not made any reduction in their prices. Of the remaining fifteen, twelve exhibitors announced reduction in prices as follows:

C. Cowles	10-40	percent
Light Mfg. & Foundry Co.	20	"
Prestolite Co.	20-22	"
Wm. Cramp & Sons	20	"
U. S. E. Corp.	40	"
Luthy Storage Battery Co.	20	"
Consolidated Utilities Corp.	20-25	"
Breeze Metal Hose & Mfg. Co.	25-33-1/3	"
Willard Storage Battery Co.	20	"
Doehler Die Casting Co.	15	"
Superior Lamp Mfg. Co.	15	"
Gemco Mfg. Co.	15	"

The remaining three exhibitors had nothing to say about prices.

These figures show that a reduction in prices has begun. This is particularly true in the case of concerns manufacturing castings, etc., rather than assembled jobs, but the twelve price reductions out of fifty-two is probably not representative of general conditions, a much larger percentage of reduction being probable in the near future.

As regards present factory production the greater number of exhibitors stated their production to be anywhere from ten per cent up to fifty per cent of capacity; 33-1/3 per cent would be a fair average figure for all the exhibitors questioned.

Out of fifty-two representative exhibitors only three the Giant Grip Co., the Sun Co., and the Biflex Products Co. announced their factories as working at full capacity production. But the number of companies whose present production is down to thirty, forty or fifty per cent stated the probability and in some cases the certainty that their factories would be working to full capacity by March of the present year.

Wages on Lower Basis

The question of wages is uppermost in the minds of nearly all the manufacturers. Factories which are operated on a production basis of even 20 or 25 per cent, already have reduced the pay of their workers from 5 to 20 per cent. In nearly every case, these cuts have been accepted willingly and the men at work have shown much greater efficiency than they did at higher wages.

It is apparent that the factory hands realize that their pay must be scaled down along with the cost of living to them. Most operators of factories which have not yet resumed production say that when their plants reopen, there will be wage cuts. There are a few notable exceptions to this rule, notably Franklin and Columbia which say they will not cut factory wage schedules until they are forced to do so.

The same stand is taken by a few other car makers whose plants are located in small towns or who produce high quality cars which they say they cannot afford to entrust to any but the most skilled workmen.

While wage cuts have not been so general in garages and service stations, the downward tendency is apparent also in this field and several instances have been reported of reductions. Here also there are reports of greater efficiency and as much work is being turned out by a reduced force.

Credit Situation Remains

Both manufacturers and dealers report little actual change as yet in the credit situation. They are hopeful however of easier money conditions in the near future and appear little concerned over the possibility of financing the business they expect to get. Manufacturers whose plants are located in the south do not expect any great improvement in the industrial conditions there until the next crop is harvested. They say that there is no real shortage of money, but that cotton, rice and sugar growers who have suffered from the slump in the value of their products feel poor whether they actually are or not. The same conditions prevail in the other great agricultural districts of the country.

Taken all in all, the keynote of the New York show is optimism. Manufacturers and dealers came here hopeful that the public would display an increased and serious interest in motor cars and they have not been disappointed. The attendance is fully as large as was expected and there is apparent an actual determination to buy cars either in the near future or as soon as spring weather comes.

Trailer Association Makes Year's Plans

J. H. Fertig Again Chosen President—Initiation Fees and Dues Doubled—Favor Show

NEW YORK, Jan. 10—Two new officers and members of the executive committee were elected by the Trailer Manufacturers' Association of America, at the annual meeting, Jan. 6 in the offices of the Association, Grand Central Palace.

J. H. Fertig, of Newark, N. Y., president, and H. C. Fruehauf, of Detroit, first vice-president, were re-elected. Max Herrmann, of Beloit, Wis., was elected second vice-president to succeed C. H. Martin, of Springfield, Mass., and Henry M. Wood, of Cincinnati, was elected secretary-treasurer to succeed J. C. Endebrock, of Cincinnati. Herrmann and Wood were also elected to serve on the executive committee.

An amendment to the by-laws was adopted doubling the initiation fee and annual dues. A code of ethics in trade practices was also adopted as an amendment, as a preventive against the creeping into the industry of any objectionable methods that might lead to lack of harmony within the organization.

The patents committee was enlarged by appointment of W. E. Ferris, of Cleveland, and I. S. Byrum, of Troy, O., to serve with C. H. Martin, of Springfield; J. W. Menhall, of Edgerton, Wis., and Max Herrmann, of Beloit, Wis. The committee was instructed to make a study of the patent situation and strive to find some plan whereby litigation between members may be avoided, thereby promoting harmony and conserving energies and resources of members which can better be expended in developing the manufacture and sale of trailers.

The standardization committee was continued, with instructions to pursue its investigations and make recommendations to the next members' meeting for standardization of trailer axles and trailer hitches.

A number of members expressed a desire to participate in a national outdoor exhibition and demonstration of motor trucks, trailers, and material handling machinery in event that plans for the promotion of such an event begin to take shape in the motor vehicle industry.

FRANKLIN STOCKS CLEARED

SYRACUSE, Jan. 10—A letter sent to stockholders by the H. H. Franklin Mfg. Co. states that 1041 cars were sold and shipped last month as compared with 826 in December, 1919. Finished cars on hand at the factory on Sept. 1 numbered 544 but none were on hand Jan. 1. The production in December was at the rate of 33 cars a day while the average for the ten months ending Aug. 1 was 39. Reports to the factory show that dealers are not stocking cars but are selling them as fast as they are received.

Rubber Association to Widen Activities

Directors to Act on Proposed Export Department—Dunn New President

NEW YORK, Jan. 11—Harry T. Dunn, president of the Fisk Rubber Co., was elected president of the Rubber Association of America at the annual meeting of the directors here. He succeeds Homer E. Sawyer of the U. S. Rubber Co., who has served two terms. The other officers chosen were: First Vice-President, F. A. Seiberling, president of the Goodyear Tire & Rubber Co.; second vice-president, Horace DeLisser, chairman of the board of the Ajax Rubber Co.; secretary and general manager, A. L. Viles; treasurer, William C. Cox. Prior to the meeting of the directors the organization elected five directors who were: Seiberling, Dunn, DeLisser, William O'Neill, vice-president of the General Tire & Rubber Co., and F. R. Henderson, president of F. R. Henderson Rubber Co., dealers in crude rubber.

The association referred to the directors the power to act on the recommendation of the general manager that an export department and a publicity department should be added to the activities of the association. This question will be considered by the directors at the meeting on Jan. 18, but it is not probable final action will be taken at that time. In his report Viles said:

"We believe that sufficient experience has been had with the potential advantage in Association work to prove the wisdom of attempting to cover the field more comprehensively and efficiently, and that our organization and activities should be extended to a degree which will make the Association a more efficient and competent piece of commercial machinery.

Educational Work Important

"If the export department is established, as it undoubtedly will be, it will help to solve problems in connection with the tire industry in foreign markets, notable among which will be educational work in the interest of the straight side type of tire equipment as contrasted with the clincher type which is being vigorously promoted by the manufacturers in Europe. The publicity or educational department will devote its efforts to the preparation and dissemination of the right kind of publicity concerning the rubber industry in general."

Another proposal made by Viles was that the subject of cost accounting be turned over to an accounting committee and a department organized in charge of an assistant experienced in stock accounting work for industrial groups. It is believed this will be of great value.

The general manager paid tribute to the work of the industrial relations executive committee and proposed that it be made a department of the association in charge of an assistant who would devote most of his attention to the preparation of accurate and timely information concerning employment conditions in various parts of the country. He also urged that additional help be provided to promote broader work along research and statistical lines.

The annual dinner of the association was held last night in the grand ballroom of the Waldorf Astoria and approximately 875 representatives of all branches of the industry were present. The attendance was considered remarkable in view of the industrial conditions which now prevail. Homer E. Sawyer, the retiring president, presided as toastmaster, and the speakers were P. E. Blondin, Postmaster General of Canada; Representative Simeon D. Fess of Ohio and Rev. Nehemiah Boynton. The dinner committee was composed of Horace DeLisser, A. W. Warren and C. W. McLaughlin.

A. B. Jones Resigns Goodrich Committee

AKRON, Jan. 10—Alfred B. Jones, vice-president and director of plant administration of the B. F. Goodrich Co. has resigned from the executive committee, the governing body of the company composed of acting vice-presidents. The resignation became effective Jan. 8. Jones' only comment upon the report current among Goodrich officials that his resignation as vice-president would be acted upon at the next meeting of directors, was to the effect that he still was an officer of the Goodrich company.

Jones returned Monday, Jan. 3, from a six months' European tour during which he made an exhaustive survey of business conditions in many foreign countries. During his absence several changes in personnel in the engineering and administration departments of the Goodrich company were made, George W. Perks resigning as director of engineering, to be succeeded by S. B. Robertson.

Jones formerly was connected with the Diamond Rubber Co. and joined Goodrich upon consolidation of the two companies in 1902. He was elected vice-president two years ago. During the war Jones gained a leave of absence and served abroad for nearly a year as American Red Cross commissioner in France.

BIDDLE ASSETS $172,063

NEW YORK, Jan. 11—Schedules in bankruptcy filed by the Biddle Motor Car Co., Inc., show assets of $172,063 and liabilities of $333,563. Among the creditors are the United States, sales tax on automobiles and parts, $4,672; Forbes-Perkins Co., Boston, $22,000, and W. H. Lippincott, $12,338. Main items among the assets are stock, $149,719; accounts, $21,312, and notes, $750.

ROLLS STARTS PRODUCTION

SPRINGFIELD, MASS., Jan. 7—The American works of the Rolls-Royce company has reopened here on a full production schedule. About 600 workers are employed and more will be added.

Truck Sales Heads Confer on Problems

Gradual Improvement in Business Continues—Used Trucks Prove Stumbling Block

NEW YORK, Jan. 12—Directors of the National Motor Truck Sales Managers' Association met here to-day to consider some of the more important problems confronting their branch of the industry. The session was a continuation of an earlier one held last Friday. The sales managers think there has been some stimulation in sales and they expect a gradual improvement in business. Some of them assert that the gain will be more pronounced than in the passenger car field. Among the companies which report somewhat better trade are Federal, Sterling, Selden, Packard and Republic.

The accumulation of used vehicles on the market is one of the greatest stumbling blocks in the way of renewed activity in the truck market. One of the main subjects considered by the sales managers at the meetings here has been the perfection of some practical plan for meeting this situation. They are approaching the subject cautiously, however, and are not disposed to make any announcement of what they propose to do until they are convinced the proposal will be workable and will result in clearing dealers floors of used trucks. It can be said that conferences have been held here with representatives of the larger finance companies whose co-operation has been marked.

The sales managers also are perfecting plans for bringing about a closer relationship between the manufacturers and the distributers. It is felt they have been working in the past at cross purposes and that this evil should be eliminated. The manufacturers are eager to do everything in their power to aid their dealers. They are striving to eradicate so far as possible the ills resulting from the sale of trucks to anyone who can be dragged in to the sales room regardless of whether he is in a position to pay for the vehicle or whether he has any real need for it.

Would Organize Dealers

Secretary Babney of the Association, is co-operating with the National Automobile Dealers' Association in an attempt to enlist a much larger representation of truck dealers in the latter organization. He believes that if there were a truck division in the N. A. D. A. an opportunity would be presented for the discussion and solution of problems common to all truck distributers.

The sales managers are considerably perturbed over the announcement that the Slough Trading Co. of London proposed to sell in this country 4000 motor trucks made by American companies but left in England by the American Expeditionary Forces.

Fuel Exports Ban Favored in Senate

Members From Agricultural States Fear Shortage for Farms —Want Lower Prices

WASHINGTON, Jan. 7 — Senators from agricultural States, particularly where motorized equipment is used extensively, have announced their intention to support the McKellar bill, which would prohibit exports of petroleum to countries declining to permit American oil producers to own or acquire oil lands. Senator Gronna of North Dakota advised the Senate that restrictions must be placed on exports of gasoline because it is impossible for farmers to operate tractors and other essential automotive farm equipment because of the high prices of fuel.

In advocating the McKellar measure, Senator Gronna declared that "the cost of gasoline affects not only the farmer but it affects the manufacturer of tractors." He pointed out that unless gasoline prices drop, farmers in North Dakota and other neighboring States would be compelled to use horses or mules to operate their farms. Senator McKellar stated that Great Britain is getting more than 50 per cent of the oil supply from this country and at the same time acquiring vast oil fields.

The bill, Senator McKellar told AUTOMOTIVE INDUSTRIES, was not inspired by the resolutions of the American Petroleum Institute which convened here in November. The Senator claimed that it was based on his personal studies and was not sponsored by American producers. He favors reciprocal agreements on oil. It was his inquiry into England's failure to pay past-due interest on loans that led to this legislation, he said. The drastic measure was provoked by payment of vast sums for oil fields and neglect to retire the debt to America. The bill is now in committee.

British Dealers Hit By Higher Plate Tax

LONDON, Dec. 14 (Special Correspondence)—One of the most objectionable terms in the Ministry of Transport's Bill now before the Lower House of the legislature is the raising of the trade license tax from about $16 to $50 a number plate. At first the rate was to be $75 per plate but this has been reduced to $50 as a sort of compromise with the trade. Even at the amended rate the tax will press heavily on dealers as well as manufacturers, because it is not a case of one plate being required, but as many plates at the same rate as the dealer or maker finds necessary for his business.

Ford dealers are expected to be worse hit by this revised tax, because all Fords are invoiced ex-factory at Manchester, where the dealers largely receive them and deliver them by road.

CONGRESS ESTABLISHES CARS AS NECESSITIES

WASHINGTON, Jan. 10—Essentiality of the passenger car is again established. Congressman James Mann of Illinois, leader of the majority of the House of Representatives testified to this fact so convincingly that opposition to appropriations for automobiles for departmental use, faded. "The automobile," says the Congressional chief, "is as much a necessity today for convenience and transaction of business as the street car is in a big city."

Congressman Mann called attention of the House to the existence of a law which was enacted at a time when farmers were disposed to fight Government encouragement of automobiles because of the effect on horses. No money can be expended for automobiles without the express authorization of Congress. The Illinois legislator believes that the law should be revoked since the farmers own more automobiles than any other class.

Appropriation Limits Aeronautic Research

WASHINGTON, Jan. 10—Aeronautical research will be restricted this year because of reduced appropriations passed by the House for the maintainance and operation of the National Advisory Committee for Aeronautics. A total of $405,266 was asked specifically for development of aeronautic power plant materials and aero dynamical research. The House appropriations committee and subsequently the whole House allowed only $260,000 for scientific inquiry and administrative expenses.

It is understood here that engineers and manufacturers interested in the promotion of the science of aeronautics intend to bring pressure to bear on the Senate in order to restore the original estimate for the advisory committee.

The estimate of $131,600 for power plant research prepared by the advisory committee was to be devoted to current problems with a view of reducing costs of engines, fuel and other maintenance charges which hinder the development of commercial aviation. The program also contained a provision for continuing the performance tests of new and improved aircraft engines and accessories.

MOBILE LOSES STOCK LICENSE

ATLANTA, Jan. 10—Alleging that the Mobile Tractor Co., of Mobile, Ala., has been proven guilty of fraudulent transactions, the Georgia Securities Commission has revoked the company's license to sell stock in Georgia. The Mobile concern is one of the largest tractor manufacturing companies in the South.

N. A. C. C. to Consider Foreign Financing

Believe New Corporation Will Have Important Part in Developing Trade

NEW YORK, Jan. 8—The part that the automotive industries will play in the formation of the Foreign Financing Corp., the export financing institution which is being organized by the American Bankers Association, will be taken up at a forthcoming meeting of the foreign trade section of the National Automobile Chamber of Commerce. In making this announcement, George F. Bauer, the N. A. C. C. foreign trade secretary, said it was hoped to have the industry well represented in the organization of the proposed banking company.

The Foreign Financing Corp. is to have a capitalization of $100,000,000, which will give it a loaning power of ten times that amount. At the recent meeting in Chicago when it was considered by bankers and business men from all parts of the country, it was decided that its capitalization would be undertaken by districts and industries. Exports from these industries and districts would be financed by the company in proportion to the amount of capital stock thus underwritten.

The meeting of the N. A. C. C. committee will take up this angle from the standpoint of the automotive industries, as it is recognized that such a financing corporation may play a big part in the future foreign trade of the United States. The committee of thirty which is organizing the bank has two automotive representatives—Roy D. Chapin, of the Hudson Motors Car Co., and John S. Raskob, of the General Motors and Du-Pont interests. In addition, J. Walter Drake, of the Hupmobile company, was instrumental in perfecting the company's plans.

A meeting of the foreign trade committee of the Chamber will be held on Tuesday, Jan. 11. This will be closed to the seven members of the committee. The next open meeting will be that at which the Foreign Financing Corp. will be considered.

ANTIGO DOUBLES CAPITAL

ANTIGO, WIS., Jan. 10—In increasing its capitalization from the original amount of $500,000 to $1,000,000 upon starting active quantity output, the Antigo Tractor Co. of Antigo, Wis., has reincorporated as the Antigo Tractor Corp. It recently purchased the foundry, machine shop and equipment of the Murray-Mylrea Co. at Antigo and began production to-day under the direction of W. L. Carver, general manager, formerly of the Mid-West Engine Co., Indianapolis. F. H. Houck, formerly with the same concern, and C. R. Parrott, until now with the Universal tractor division of the Moline Plow Co., will be Carver's chief aides.

Confidence Features 21st N.A.C.C. Dinner

Enthusiasm Manifested at Show Kills Fears of Continued Depression in Industry

NEW YORK, Jan. 12—Nearly 700 representatives of the automotive industry, most of them passenger car makers and officers of their companies, attended the 21st annual dinner of the National Automobile Chamber of Commerce at the Commodore last night. There was no atmosphere of gloom but rather the reverse. The diners seemed to feel that the worst is over.

"I believe the tide has turned," was the smiling declaration of Edward R. Tinker, vice-president of the Chase National Bank and one of the leading automobile bankers of the country. He was one of the dominating factors in the reorganization of the Maxwell and Chalmers companies and has complete faith in the future of the industry.

"Things aren't so ——— bad as they have seemed," declared Col. Charles Clifton, president of the N. A. C. C. and one of the "grand old men" of the industry in his opening remarks as toastmaster.

The note of confidence which has permeated the show dominated the dinner. The men who attended were a bit more serious than they have been some other years but the seriousness was born of determination to succeed rather than discouragement. It was significant that a score of the most prominent automobile bankers in the city were interested guests.

Francis H. Sisson, vice-president of the Guaranty Trust Co., who discussed the economic situation from the viewpoint of a banker, declared the most critical of the post-war readjustments have been passed, although many more must yet be made. The most important of these, he said, is the adjustment of retail prices to declining wholesale prices and the costs of production to present purchasing power.

Wage Adjustment to Cut Cost

"The adjustment of production costs will consist chiefly of wage readjustments," he said. "although increased efficiency and decreased margins of profit will play their part. The laborers who profited most from the ever-soaring wages during the war and for some time after will feel the curtailment first and most, but they should be in a better position to bear it than their less fortunate fellow-workers.

"We are not in the throes of overproduction, but merely temporary underconsumption. And it is significant, in this connection, to note that when goods are offered for sale at retail prices which the public believes to be fairly commensurate with prevailing wholesale prices and costs of production they are eagerly bought. Despite the materially lessened purchasing power in agricultural sections, occasioned by the precipitate decline in the price of farm products. and in certain industrial sections, because of closed plants or the part-time operation of factories and reductions in wages. there is still a tremendous buying power and always will be.

"Wages cannot be sustained on an uneconomic basis any more than can farm products or any other commodities. All necessary liquidations must run their course, and the sooner and franker we face that fact and discount its inescapable consequences the better off we shall be. The producers and merchants who persist in holding their goods for prices that the public will not pay are courting disaster and preparing to swell the number of commercial failures. They have not learned the elemental rule of successful merchandising that profits come from turning over capital. They are endeavoring to ignore the inexorable law of supply and demand.

"American business men must recognize the vital fact that one of the most important factors in our prosperity henceforth will be our foreign trade. The extent to which our overseas trade is sustained and increased will depend to a large degree upon the methods devised for financing it.

World Looks to United States

"The world to-day looks to the United States as the one solidly fortified nation in the realm of finance and trade. No other country has to a like extent the great power needed to meet the present emergencies.

"As on a memorable occasion when Marshal Joffre decided that France would not yield another foot of ground and determined that the enemy should not pass at the Marne, the American people have reached the point in their post-war economic readjustments where they are called upon to stand firm to stop retreating and go forward. The present hour calls not so much for better conditions as it does for stronger courage; the existing situation requires less confusion, and more confidence."

The annual awards of medals evoked howls of mirth. The victims were Walter P. Chrysler, Henry M. and W. C. Leland, Windsor T. White, Emlen S. Hare and A. I. Brousseau, president of the International Motor Co.

Chrysler was told he was decorated because he had been so successful in standing around where he could be "discovered" by C. W. Nash and John Willys. His medal was given for his success in ironing out complications in the industry and it was remarked he found time to get behind the scenes in the Maxwell-Chalmers two ring circus.

The diners rose to greet Henry M. Leland and his son when they were called to the platform. They were told they had been summoned to find out when they would get into production and they were advised that if they had made mistakes not to admit them now but to wait until their car gets into the hands of the people.

White "Blazed" Industry's Way

White was complimented because he had "blazed" the way for the industry "in an inflammatory sense." It was remarked that he had "removed some of the surplus weight" from his passenger car "and labelled the invention a truck."

Hare was hailed as a man who was brave enough to tackle anything and one who, in the goodness of his heart, had rescued "several grand old museums of by-gone days."

Brousseau, it was asserted, was most revered by the road building machinery dealers because he was the maker of "graceful rolling warehouses" which were invaluable as road destroyers.

Maxwell-Chalmers Assets $41,000,000

Consolidated Companies on Sound Basis for Operation—Inventories Written Low

NEW YORK, Jan. 12—After weary months of conference and compromise the reorganization plan which will bring about a formal consolidation of the Maxwell Motor Car Co. and the Chalmers Motor Corp. was declared operative yesterday by the managing and reorganization committee headed by Walter P. Chrysler and J. R. Harbeck. More than 87 per cent of the outstanding stock of the two companies has been deposited under the plan, but the committee is extending until Feb. 1 the time under which deposits of stock and unsecured claims can be made without penalty. The following statement on the financial status of the new organization was made by Harbeck:

"The new company is now placed in an extremely fortunate position to face the conditions confronting the automobile industry. The net outstanding obligations of the Maxwell and Chalmers companies have been reduced, through liquidation, by approximately $11,000,000. This liquidation has been largely through the sale of cars in dealers' hands, resulting in a reduction of the companies' obligations arising from the discounting of dealers' notes, paper, etc. The merchandise and bank creditors are to be amply protected through substantial cash payments and the funding of the balance of the obligations upon a one, two and three year serial note basis.

"The new company's balance sheet shows net current assets of about $41,000,000 after depreciation, and net current liabilities of about $6,000,000, the ratio of current assets to current liabilities being approximately seven to one. Inventories have been substantially written down, so that the reorganized company will not be handicapped by having to take into 1921 operations losses chargeable to previous years.

"The reorganized company may be regarded as being upon a sound basis for profitable operation on the basis of reduced sale prices. During the reorganization period points of contact with the public have been more than doubled through establishment of additional selling agencies and branches.

"An analysis of the balance sheet, after excluding good-will and allowing $100 per share for the A shares, which are preference shares, shows a book value for the B stock of approximately $30."

SURPLUS WAR PLANES SOLD

NEW YORK, Jan. 10—The Aeromarine Plane & Motor Co. has taken over $4,000,000 worth of surplus naval aircraft and engines. This marks the first step in the retirement of the Government's surplus aeronautic stocks.

Wall Street Sees Good Normal Year

Tendency Probable Toward Consolidation of Weak Sisters—Stocks Show Gains

By JACQUES COHEN
of J. S. Bache & Co.

NEW YORK, Jan. 13—The recent recovery in the prices of industrial stocks has been fully reflected in automobile stocks as well. Wall Street was extremely bearish on motor stocks during the last two months of 1920 with the result that there was built up in this group what is commonly termed an "overcrowded short interest;" in other words, people speculatively inclined believed motor stocks were definitely on the downward grade and would have no chance of recovery for a long time to come. These people sold stock in anticipation of buying back cheaper. Consequently there was established a potential buying power which, once it got under way, generated sufficient momentum to make those people who were "short" run to cover.

The general consensus in Wall Street seems to be, however, that this recovery in motor stocks is temporary and that, after the recovery has run its course, security prices will again lapse toward a lower level, but not so low as the low prices of December. Then Studebaker sold at 37¾, General Motors at 12⅞, Willys-Overland at 5⅛, Pierce-Arrow at 15 and White at 30½. At present, prices recoveries have been anywhere from 3½ points in General Motors to 18 points in Studebaker.

The stocks of finished cars on hand are considerably below the high point a few months ago and are gradually being reduced to a point where production on a conservative basis will meet the demand and prevent a recurrence of a period of saturation such as we had three or four months ago.

Credit Burden on Banks Easier

There has been some speculative enthusiasm because of the automobile show and the presence here of important automobile officials for that event. The bright spot on the horizon, however, is the fact that curtailment of production and the gradual reduction of inventories will increase working capital to a point where the banks will be substantially relieved of their carrying loads and the industry as a whole will rapidly recover in health.

Prominent bankers seem to agree that the outlook for this year is not so bright as it was for 1919 and 1920 but that, on the whole, business will be fairly good and that there will be a tendency toward consolidation of "weak sisters" for the purpose of bolstering up the industry as a whole. Consequently, an era of consolidation may be looked forward to with eventual improvement in security prices, since Wall Street always views consolidations and mergers of companies in a favorable light.

Report Ford to Offer $100,000,000 in Stock

NEW YORK, Jan. 12—Financial circles in this city have been deeply interested this week in circumstantial reports that Henry Ford proposes to offer to the public in the near future an issue of $100,000,000 participating 8 per cent preferred stock of the Ford Motor Co. The stock would participate in the earnings of the company up to 12 per cent, it is stated, but would have no voting power.

Ford does not intend to offer any part of the stock to the banks, it is said, but intends to sell all of it to the public. He is reported to be confident that he would have no difficulty in disposing of it to the public and that the offering would be over-subscribed quickly.

Although official confirmation of the report is lacking, bankers here are inclined to believe it is true.

Remy Reduces Wages; Other Units Not Bound

ANDERSON, IND., Jan. 10—A general wage reduction of 20 per cent has been made by the Remy electric division of the General Motors Corp. The plant has been shut down practically since early in December, but in the past few days almost 100 men have been put back to work at the new wage scale in the service department. It is believed that other departments will resume within the next month. At the time the Remy plant shut down in December it was employing 1000 persons as against 3000 two years ago.

No Simultaneous Cuts

NEW YORK, Jan. 10—It was said at the headquarters of the General Motors Corp. that the action of the Remy Electric Division does not mean simultaneous wage cuts in all the parts plants of the corporation. Advisability of wage reductions will be determined by the managers of the individual units and will depend largely upon local conditions.

FORD LAND INCORPORATED

HOUGHTON, MICH., Jan. 10—Articles of incorporation for the Michigan Iron, Land & Lumber Co., capitalized at $2,000,000, have been filed by Henry Ford, Edsel Ford and Clara Ford. The company was formed to take over the assets of the Michigan Iron & Land Co., which was purchased by the Fords several months ago. It will do a general manufacturing lumbering and mercantile business. The main business will be the working up into automobile parts of lumber cut from the company's holdings. This will be done at the new Iron Mountain plant. The property comprises 68,000 acres, rich in iron ore and it is expected the Fords ultimately will engage in mining operations.

Truck Census Seen as Aid to Selling

N. A. C. C. Committee Authorizes Complete Survey of Country—Endorse Uniform Law

NEW YORK, Jan. 12—A census of the motor trucks in the United States was authorized by the Motor Truck Committee of the National Automobile Chamber of Commerce at its meeting here yesterday. It will extend to all communities in the country and will determine the conditions of the trucks, for what they are being used and their tonnage. The information would inform manufacturers on the extent to which motor trucks have been sold and would give valuable information regarding potential markets. This census will be supplemental to the survey now being made of the use of motor trucks on farms and when both are complete it is expected that practically every truck in the country will be listed.

The committee endorsed the provisions and alterations in the proposed uniform motor vehicle law as recommended by the Motor Vehicle Conference Committee.

Serious consideration also was given to the subject of highway impact tests which are being made by the Federal Bureau of Roads. The committee is ready to co-operate in every way in its power in the development of the nation's highway system.

Information has reached the committee disclosing that state highway departments are renting trucks given them by the government to county highway supervisors at the rate of $25 a year.

Sale of Used Trucks Is Started on Coast

LOS ANGELES, Jan. 10—Colonel Pierce is here with seventy-five Packard and Riker trucks brought from abroad and starts the sale of them Wednesday through a local dealer. The truck industry here is greatly disturbed and has appealed to the National Automobile Chamber of Commerce and the National Automobile Dealers' Association. The sale of these trucks, it is feared, will demoralize the used truck market and have a bad effect on the new truck business.

Colonel Pierce, the American representative of the Slough Trading Corp., has declared that if the trucks meet satisfactory demand hundreds more will be brought into the country from abroad. They are all of American manufacture which were turned over to the British.

DECEMBER PRODUCTION DROPS

NEW YORK, Jan. 13—December shipping figures gathered by the National Automobile Chamber of Commerce show that 11,814 carloads of passenger cars were shipped last month and that there were 6500 driveaways.

Team-work Wanted, Parts Men Are Told

M. A. M. A. Hears Inspirational Talk by G. M. Graham—Dinner Big Success

NEW YORK, Jan. 13—Nearly 400 members of the Motor and Accessory Manufacturers' Association attended the annual meeting of the organization at the Biltmore yesterday afternoon. The attendance came close to establishing a record and demonstrated that a large number of representatives of this branch of the industry are attending the show. The feeling among the members was optimistic and confidence was expressed that there will be a slow but steady improvement in business from now on.

The annual meeting this year offered an innovation. The usual lengthy reports covering the activities of the organization were eliminated and an inspirational address by George M. Graham, sales manager of the Pierce-Arrow Co., substituted. Graham pointed out the community of interest which exists between the parts and vehicle manufacturers. He told why there need be no fear about the future of the industry and asserted that conditions would improve from now on although the problem is to get away slowly and gather momentum as the year advances. He declared the men in the industry are courageous and for that reason are hanging on so gamely that there need be no fear of disaster.

The meeting was a fitting preliminary to the annual dinner last night. The feast and fun festival was fully up to the high standard already set and there were no dull moments for the 500 diners. Sidney S. Meyers, general counsel of the association, acting as impressario, transported Florenz Ziegfeld and the "Midnight Frolic" bodily from the New Amsterdam Roof.

The banqueters liked the show and showed their approval by generous applause. The performance ran as smoothly as it would if the performers had been at home. The music was by the "Midnight Frolic" orchestra. An ample stage had been built for the occasion at one end of the grand ballroom of the Commodore, where the dinner was served. Meyers and the other officers of the association were showered with congratulations upon the success of their efforts. According to the custom of the M. A. M. A., there were no speeches at the dinner.

Austin Makes Plans for Large Production

NEW YORK, Jan. 12—Manufacturing plans of the Austin Motor Co., Ltd., Birmingham, England, call for a production in 1921 of 10,000 automobiles, 10,000 farm tractors, 5000 trucks, 7500 farm light plants and 1500 airplanes, according to Major H. J. Cupper, American representative of the company, who is showing the Austin car and chassis at the Waldorf-Astoria during show week here.

The company is planning to export 1000 cars to the United States in 1921, the Major declared, and hoped to increase this number to 3000 in 1922. Sales offices and parts stations will be established in New York, Philadelphia, Washington, Chicago, Detroit, Boston, Atlanta, Los Angeles, San Francisco and Seattle. Wholesale branches will be maintained in New York and Montreal.

The Austin company passed the dividend on its preference shares early in January to conserve finances.

Haynes Is Elected to Dodge Presidency

NEW YORK, Jan. 12—The election of F. J. Haynes to the presidency of Dodge Brothers, at a directors' meeting in Detroit yesterday, was greeted with great enthusiasm by Dodge dealers attending a show luncheon at the Waldorf-Astoria here. Announcement of the election was made by Charles W. Matheson, general sales manager, who was presiding at the dealers' meeting. Howard B. Bloomer, personal friend and attorney to John and Horace Dodge, was elected chairman of the board of directors.

Haynes has been with Dodge since 1912, beginning as factory manager and working his way to the vice-presidency and general managership. He was with Franklin from 1901 to 1912 and prior to that had been with the E. C. Stearns Co., Toronto, and the National Cycle & Automobile Co. Haynes was superintendent of the Hamilton plant of the National company and there first became associated with John Dodge, then general manager there.

INDUSTRY URGES AIR MAIL

WASHINGTON, Jan. 12—Manufacturers of aircraft and industry in general are making a determined fight here this week to induce the Senate to restore the appropriation for the Air Mail Service which the House eliminated in passing the Post Office bill last week. The entire item was stricken from the House bill. The House Committee on Post Offices and Post Roads had recommended the appropriation of $1,250,000 or $2,250,000 less than the departmental estimates.

TAKE OVER AMERICAN BUS

CHICAGO, Jan. 12—The reorganization report on the American Motor Bus Corp., and the Chicago Motor Bus Co., submitted by Harold Almert, consulting engineer, has been adopted by the bankers, and the business of the two concerns taken over by the Lake Shore Motor Bus Corp., a holding company.

The American Motor Bus Corp., the manufacturing concern, has resumed the manufacture of front wheel drive, stepless type, motor buses and is bringing out a new double deck bus with a seating capacity of sixty passengers, with both upper and lower decks fully enclosed. The initial order will keep the factory operating at full capacity for the year 1921.

Retail Sales Show Business Returning

Placing of Dealers' Orders Indicates Good Spring Trade for Manufacturers

NEW YORK, Jan. 13—Retail sales in as great a volume as have been made at any New York show except that of 1919 are recorded as the week ends. The 1919 show, staged by the New York dealers and presenting automobiles publicly for the first time after the armistice, was phenomenal as a selling agency. But sales this year are fully up to those of the 1920 exposition in practically all lines of cars. Attendance to date is 10 per cent ahead of last year. Some remarkable prospect lists have been made up.

Attendance of dealers, particularly from the Eastern territory, is better than the average at a New York show. Dealers appear to have come in for two purposes, to feel the buying pulse and to obtain merchandising ideas. The crowds and the buying at the show have induced placing of orders for resumption of shipments of cars under allotments, not in many cases up to 100 per cent but in sufficient degree to encourage many manufacturers to proceed in anticipation of a good spring business.

A meeting of the Eastern Automotive Equipment Association early in the week and patronage of the equipment exhibits at the Palace reveals a gradual, yet steady, return of buying. in this field.

Higher Car Tariff Opposed by N. A. C. C.

NEW YORK, Jan. 13—Directors of the National Automobile Chamber of Commerce decided at a meeting yesterday to join with the National Founders Association in opposing an increase in tariff duties on aluminum. It is contended that the aluminum industry is virtually a monopoly now and that it needs no protection. A higher tariff would not result in increased revenue, it is held, because it would curtail imports.

Representatives of the N. A. C. C. will appear before the House Ways and Means Committee at Washington tomorrow to protest against the imposition of higher duties on automobiles and urge that all automobiles, regardless of value, come under the 30 per cent rate. An increase in tariff imposts would result in penalties being applied to American cars by other countries, the industry believes, and cause a reduction in the volume of exports.

A. J. Brousseau, president of the International Motor Co., was designated to represent the N. A. C. C. on the National Research Council.

The directors adopted a resolution expressing deep regret at the death of Horace E. Dodge. They elected Frederick J. Haynes, the new president of Dodge Bros., a director to succeed Dodge.

Goodyear Financing Matter of Selection

Choice of Several Plans Rests With Backers — Propose Organization Changes

NEW YORK, Jan. 12—Considerable progress is being made in the difficult tasks of readjusting the financial affairs of the Goodyear Tire & Rubber Co. Several plans have been taken up by the bankers interested as well as by unsecured creditors. One of these calls for an issue of junior securities to protect the claims of the unsecured creditors and a first mortgage to cover the bank borrowing.

Whatever plan is worked out, it is proposed to make important changes in the management of the corporation, and it can be said upon authority that a strong corporation executive will be placed in a position of authority so that he can readjust the affairs of the company on a sound operating basis.

The main difficulty now is getting the various interests to agree upon some basis of adjustment. There is every reason to believe that this ultimately will be done. The great tire company is entirely solvent and its difficulties are the result of the general financial and industrial depression. It is expected that the details of refinancing will be announced at the next meeting of the stockholders.

The merchandise creditors have declined to accept a proposal to take 75 per cent of their claims in cash and the balance in 5-year bonds. They have made a counter proposal that they be paid 60 per cent in cash and be given 1-year notes for 20 per cent and 2-year notes for the remainder. Their theory in this plan is that the notes would be virtually negotiable.

The preferred stockholders of the Goodyear Tire & Rubber Co. adjourned until Jan. 21 at a meeting held this morning. No announcement regarding the refinancing was made.

Cobleigh and Reeves Talk to Service Men

NEW YORK, Jan. 12—Over one hundred service executives attended the second annual convention of Automotive Service Associations held at the Hotel Commodore all day Monday. A number of prominent speakers addressed the delegates and plans were made to co-ordinate the efforts of the various associations, of which there are eleven at the present time. The morning session was devoted to reports from the delegates and the address of welcome by H. R. Cobleigh, secretary of the Service Committee of the National Automobile Chamber of Commerce.

Cobleigh briefly told of the early struggles of some of the associations; of the interest of the manufacturers in the movement, and of the formation of the Service Committee which, among other things, was formed to get a point of contact between factory service managers and local service managers. He predicted great strides during the coming year. Activity reports were read by delegates of the Brooklyn, New York, Newark, Baltimore, Western Massachusetts and Syracuse Automotive Service Associations and the Automotive Electric Service Association.

Army Not Contracting for Additional Trucks

WASHINGTON, Jan. 11—Reports current in the industry that the War Department refused to release truck manufacturers from contracts while Congress was proposing to dump the army surplus trucks on the market were officially denied at the War Department to-day. It was stated that the army is not buying trucks at present because it has adequate equipment on hand.

The announcement that truck manufacturers at Kenosha, Wis., were resuming production of War Department contracts is true, it was said. The Winther Motor Co., the Marwin Truck Co., and the Kenosha Wheel & Axle Co. took over the completion of a contract awarded the Sinclair Motors Co. in December, 1919. This contract called for the delivery of 75 militor tractors in May, 1920.

According to the War Department it was owing to financial difficulties that the Sinclair Co. transferrred the contract. The tractors represent a special experimental type designed by the Westerfelt Board for use with artillery. The total value of the contract is estimated at $600,000.

Winther Starts Contract

KENOSHA, WIS., Jan. 10—The Winther Motor Co., the Marwin Truck Corp., and the Kenosha Wheel & Axle Co, are preparing to resume production on a maximum capacity schedule by the end of this month in order to handle a large Government contract amounting to more than $3,000,000 and calling for 300 1½-ton and 75 3-ton trucks. The contract was issued by Charles Margerum, of the motor vehicles branch at Washington. All of the trucks will be of the quadruple drive type.

KENDAL RECEIVER ASKED

CANTON, OHIO, Jan. 10—Suit has been filed here asking for the appointment of a receiver for the Kendal Tire & Rubber Co., Massillon, by Charles Russ, a stockholder. The petition declares that the company has never manufactured any tires except a few samples. It is further declared that the plant has been sold to the Ariston Tire & Rubber Co., Chicago, by the promoters and officers who control a major part of the common stock. Russ alleges in his petition that the rights of the original stockholders were not safeguarded and asks that the sale be set aside and a receiver appointed.

Government Settles Templar War Claim

Payment of $650,000 Eases Financial Burden—To Proceed With Production

CLEVELAND, Jan. 10—The financial condition of the Templar Motor Co. has been improved materially by the settlement of the company's claim for war work against the United States Government. The claim was settled for approximately $650,000 under the Dent act and about all of the money has been paid.

The original claim was for $1,000,000 and the settlement is regarded as an equitable one. While it does not mean the full amount of the claim, deduction having been made for interest on delayed settlement and profit which would have been realized had the contract been fully completed, it nevertheless reimburses the Templar for all the money spent in changing over the plant for war purposes, materials bought, etc., and allows them a profit on the work actually completed.

The settlement puts considerable cash into the company's treasury which will be of assistance in carrying the present inventory and in manufacturing cars during the winter months for spring production.

Bramley Heads Safety Council

CLEVELAND, Jan. 10—M. F. Bramley, president of Templar Motors, has been elected president of the Cleveland Safety Council, an organization that is waging a fight to cut down automobile accidents. J. V. Whitebeck, of the Cleveland Automobile Co., is a vice-president of the council.

DODGE ESTATE TO WIDOW

DETROIT, Jan. 2—The will of Horace E. Dodge, filed for probate to-day, leaves practically the entire estate, estimated at $50,000,000, to Mrs. Dodge and Howard B. Bloomer, chairman of the board of the Dodge Bros. Motor Car Co., as trustees. The widow will receive the income until her death, when the estate will be divided equally between the two children, Horace E. Dodge and Mrs. Delphine Dodge Cromwell, provided they are 30 years old. If they have not reached that age the property will be held in trust until they are 30.

DUNLOP SUSPENDS OPERATIONS

BUFFALO, Jan. 13—Directors of the Dunlop Tire & Rubber Co. have issued a statement announcing that "general conditions in the automobile industry are such" that they are justified in practically suspending operations. April 1 has been set as the date for resumption, although it may be earlier. The British Dunlop Co. has stated that negotiations were pending in this country for a large loan to the American company by American capitalists.

Military Necessity May Retain Trucks

General Staff Likely to Win Point in Controversy Over Anthony Proposal

WASHINGTON, Jan. 11—Investigation here discloses that there is little probability that Representative Anthony of Kansas will be successful in his attempt to have dumped on the public some 20,000 motor trucks owned by the War Department. He has made this proposal as a measure of economy and it has been given serious consideration but it has met with the strenuous opposition of the General Staff and military considerations are likely to win the day.

Anthony has asserted that the army has many more trucks than it needs except in case of war and it is his idea that if a military emergency arose the trucks needed could be commandeered. The answer of the General Staff to this suggestion is that if trucks were commandeered it would be impossible to service them and that the question of replacing essential parts would offer an insurmountable obstacle to the success of the plan.

Since the beginning of the war the army has purchased approximately 64,000 motor vehicles, trucks and passenger cars. It has disposed of 34,393, most of which went to state highway departments and departments of the government. The trucks on hand Jan. 1 numbered 29,881. It is contended there is no surplus now but it is expected that in the near future the army will dispose of 6,850 trucks and 680 passenger cars. This would leave only 22,785 motor vehicles on hand. Of this number the National Guard of the various states will be supplied with 2,479 trucks and 166 passenger cars.

Under the law the vehicles which the army does not need must be turned over to other branches of the government. New legislation would be required before they could be sold to the public and it is not believed probable that there will be any amendments to the law at this session.

TO SELL CANTON COMPANY

CANTON, OHIO, Jan. 10—A court order has been issued calling for the sale on Jan. 22 of the assets of the Canton Automobile Parts Mfg. Co. which went into receivership several weeks ago. The court ordered that the property must not be sold for less than $50,000. It was organized to manufacture a new kind of piston ring.

EVINRUDE IN NEW PLANT

MILWAUKEE, Jan. 10—The Evinrude Motor Co. of Milwaukee, pioneer manufacturer of detachable gas engines to propel rowboats, canoes, etc., has moved into its new plant, occupying a tract of six acres. It will put into production a new type of oil engine for farm and similar purposes, in addition to greatly increasing its output of rowboat motors. The main shop is 200 x 300 ft.; the foundry, 75 x 100 ft., and the boat shop and warehouse, 100 x 150 ft. The company was founded in 1912 by Ole Evinrude, inventor of the detachable boat engine. It has outgrown three plants in eight years. The present capitalization is $500,000, and the principal officers are C. J. Meyer, president, and Hugo Biersach, secretary and treasurer.

C. G. Spring Acquires United States Bumper

KALAMAZOO, MICH., Jan. 10—The C. G. Spring Co., has purchased the assets and business of the U. S. Automobile Bumper Co., Chicago, and will move the industry intact to this city, doing all manufacturing here. The addition of this line to the present product of the plant will not require any extended layout for buildings or equipment, at least not for the time being.

Another step in the expansion of the C. G. Spring Co. is the announcement that the concern has opened branch service and repair stations in Detroit and Chicago. The Detroit station is on Woodward avenue, near the Cadillac plant, while the Chicago branch is at 3021 Michigan avenue. They will specialize in repairs to springs and replacements, also in the installation of the new type bumpers. These stations will be under the supervision of D. M. Short, who was associated with Girl, during the latter's connection with the Perfection Spring company.

At a special meeting of the directors, held Friday afternoon, Fred R. Eaton, cashier of the Kalamazoo National bank was elected to membership on the board. Eaton's acceptance of membership on the board adds to the conservative strength of the institution and meets with general favor in local financial and manufacturing circles.

SUBMIT TRUCK UTILITY BILL

DETROIT, Jan. 7—The bill extending the powers of the State Utilities Commission to cover the operation of the motor truck lines was introduced in the Michigan Legislature by Representative L. G. DeFoe. The bill stated that the motor truck lines have become an important part of the transportation system in competing with railroads and interurbans, and is at present without State control as to rates and service. This measure will provide supervision.

TO MOVE TRACTOR EXHIBITS

COLUMBUS, OHIO, Jan. 10—The management of the National Tractor Show has arranged with the Columbus Transfer Co. to take care of all freight shipments to the show in the event the exhibitor has no Columbus connection. The rate from the freight houses to the fair grounds will be $3.50 a ton and from the switch at the fair grounds to the show buildings, $3.50 a ton.

METAL MARKETS

PRICE movements during the next few weeks are almost certain to be devoid of the spectacular. In the pig iron market the trend is still declivous, what little activity being noticed consisting of resales of odd lots of foundry iron at prices much closer to a $30 base than the quotations of producers. In a condition emphasized by an excess of supply over demand this denotes the direction in which the market is headed and, taking the past relationship of pig iron values to those for semi-finished and finished steel into account, readjustment of the former can hardly be considered completed until after $30, valley, quotations represent the maximum, ranging down to a minimum of at least $1 to $2 below that figure. This, at least, seems to be the attitude of quite a number of buyers who are holding off until sufficient time has passed to show whether their judgment is correct or not. Numerically, there is a gratifying amount of inquiries from the automotive industries for finished steel, albeit nearly all of these inquiries are of a tentative character and the tonnages involved, compared with those customary last summer, light. In other words, a large number of small orders are hanging fire. The tardiness which characterizes these negotiations is to be ascribed to two causes. In the first place, a number of automotive buyers are endeavoring to hold off committing themselves until they have gained a somewhat better idea of the 1921 prospects for the sale of their own products. The second reason for procrastination is that there are still those who do not think that the declines in the steel market will stop at adoption by the independents of the Corporation's price levels, but that a waiting attitude on the part of buyers will force the independents' prices still further downward. The steel market's best judgment is that, if such recessions ensue, they will be general, with the Corporation taking the lead and, furthermore, that it will be two to three months before such a contingency will have to be reckoned with. By that time readjustment of wage scales will have been completed and, if a latent demand which can be forced on to order books through price reductions, is visible, say, by March 15, those who are shaping the steel industry's price policy will not be slow in resorting to such a step. Price reductions in the steel industry are, in fact, invariably made on the eve of a transparent buying movement and never when the demand would be light in spite of lower prices. By this is not meant that there may not be some slight readjustments long before the Ides of March. In fact, here and there rumors are heard even now of this or that independent being disposed to cut under the Corporation's price for some specialty. So far, these instances are exceptions, however, proving the general price uniformity rather than the opposite.

Pig Iron—Malleable is still offered for resale in limited tonnages by a Detroit automotive interest at $31. There is no question that much iron is available on a $30 basis, not only in the valley, where that level has come to be the Basic quotation, but also at Buffalo and other furnace and distributing points.

Steel—Automobile sheets rule quiet and steady. Some contracts are pending. Prices on cold rolled strip and most other grades of steel are being maintained largely because producers recognize slashing would not serve to stimulate buying.

Tin—This metal moves in harmony with pound sterling exchange.

FINANCIAL NOTES

Black & Decker Mfg. Co., Baltimore, has declared a dividend of 2 per cent on the common stock, payable to stockholders of record Dec. 30. This makes a total of 7 per cent paid during the year on the common stock of the company. Regular payments also have been made on the preferred. This showing is regarded as somewhat remarkable, in view of the general depression and the passing of dividends by many companies.

Kahlenberg Bros. Co., of Two Rivers, Wis., a large builder of oil engines for marine uses, has increased its capital stock from $75,000 to $300,000 to accommodate the expansion of its plant and business. It is filling large domestic and export orders and making shipments to China, Alaska, Cuba and other countries steadily. William Kahlenberg is president.

Parenti Motors Corp., Buffalo, at a shareholders' meeting Jan. 3, increased its capitalization from $2,500,000 to $11,000,000, to provide for expansion. The original capitalization was $1,000,000 preferred and $1,500,000 common and the increase consists of $10,000,000 common of $10 par value. The original issue is all subscribed.

Pierce-Arrow Motor Car Co. financial position is shown to be exceptionally strong with current assets in the ratio of nearly 4 to 1. Inventory is about 20 per cent larger than a year ago because of preparations for production of the new model. Sales for the year were 20 per cent lower than in 1919.

Fisher Body Corp. will pay a dividend of 1¾ per cent on the preferred stock of the company on Feb. 1. A dividend of $2.50 a share will be paid on the same date on the no-par common stock of the company.

Kelly-Springfield Tire Co. has declared dividends of $1 and 3 per cent in stock on the common stock payable Feb. 1, and a quarterly dividend of $2 on preferred stock payable Feb. 15.

United States Rubber Co. will pay a regular quarterly dividend of $2 a share on its first preferred and $2 a share on common stock on Jan. 31.

Mullins Body Corp. declared the regular quarterly dividends of $1 a share on common and $2 a share on preferred stock payable Feb. 12.

India Tire & Rubber Co. paid a dividend of 1¾ per cent on its preferred stock and 2 per cent on common stock on Jan. 10.

Standard Motor Construction Co. has declared a dividend of 2½ per cent payable February 1 to stockholders January 3.

Pawling & Harnischfeger Co., Milwaukee, has increased its capitalization from $1,000,000 to $3,000,000.

Briscoe Motor Corp. has deferred payment of the usual quarterly dividend on preferred stock.

Vulcan Automotive Parts Co., has increased its capital stock from $2,000,000 to $10,000,000.

Wilson Tire & Rubber Co. will not pay any dividends on its capital stock for the year 1921.

Steel Products Company on Three-day Basis

LANCASTER, PA., Jan. 11—Conditions as reflected by two big local plants engaged closely with the automobile trade are in direct contradiction to each other. Officials of the Rowe Motor Truck Co. announce that $1,000,000 of the company's 8 per cent preferred stock has been underwritten and will be expended to carry out a general broadening policy.

Officials of the Steel Products Co., one of many plants operated by the General Motors Co., has announced that, starting immediately, the plant will work but three days each week until further notice. This order follows the laying off of several hundred workmen and a big reduction in salaries.

Precision Castings in Receiver's Hands

SYRACUSE, Jan. 12—C. Hamilton Sanford is named receiver of the Precision Castings Co., Inc., of Fayetteville, in an order signed by United States Judge George W. Ray, which enjoins creditors from bringing action, or taking other proceedings against the company. Pressure brought to bear by a number of creditors is responsible for an equity action instituted to conserve the company's assets during the period while collection of accounts due from large automobile corporations is at low ebb. The suit was started by the Greenwich Trust Co., of Greenwich, Conn.

Federal Rubber Starts 40 Per Cent Capacity

MILWAUKEE, Jan. 10—After a curtailment of production for about a month, the Federal Rubber Co. of Cudahy, suburb of Milwaukee, resumed operations to-day with a force of about 900 men, or about 40 per cent of capacity. According to Arthur A. Frank, factory manager, business has improved substantially while a proper readjustment of stock and materials has been effected. He looks for continued increase in operations from this time forward. The Federal was one of the last of the larger tire manufacturers to curtail when over-production set in.

FACTORY EXECUTIVES ASSUME ACTIVE ROLES

(*Continued from page* 87)

Dixie Flyer—Stephen Miller, vice-president and sales manager; E. Palmer, manager of export department.

Lincoln—R. C. Getsinger, sales manager; A. H. Schiappacasse, service manager; F. G. Eastman, advertising manager; E. E. Sweet, consulting engineer; T. H. Mueller, chief engineer; W. W. Robertson, service engineer.

Lafayette—Leo N. Burnett, advertising manager.

Studebaker—William A. Morrow, general sales manager.

Monroe—President William Small; George Seibert, sales manager; Glen Todd, secretary-treasurer.

Paige—G. B. Gaunt, sales manager; John Germontrez, engineering department.

Stutz—T. L. Marshall, sales manager.

Pilot—Joseph W. Connor, sales manager.

Hanson—Charles A. Verlin, eastern factory representative.

Kline—L. H. Travers, sales manager.

Reo—R. E. Olds, president.

Nash—C. W. Nash, president.

Bank Credits

Written exclusively for* AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.

NEW YORK, Jan. 13—The new year began with sharp upturns on both the stock and bond markets. Practically the whole list of bonds moved upward, with especially noticeable improvement in the Liberty issues. There were indications that investors, as distinct from professional traders, were coming into the market. There was also a marked upturn in foreign exchange markets last week. Sterling advanced over 10c last week, and on Monday of this week it reached $3.73½, the highest since early in August of last year. This rate is 30½ cents above the minimum of last December, and 55½ cents over the low record made in February of last year. Exchange on most of the continental countries moved up sympathetically with the pound sterling.

While price recessions continue, with indications that retailers in some lines are taking their losses, there has been some resumption of industrial operations following wage adjustments, particularly in the textile field. Slackening of activity, on the other hand, continues in the steel industry, with the closing of mills more than offsetting the reopenings. For the month of December there was a net loss of 51 mills in operation. The U. S. Steel Corporation is still operating at a little more than 90 per cent of capacity, in spite of the fact that the Corporation's last monthly statement of unfilled orders indicated further curtailment in the industry.

Business failures are still on the increase, as evidenced by the December returns. The number of failures at 1,525 compares with 1,050 in November, and the liabilities involved in the December failures made a new high record at $58,871,545. This compares with $30,758,136 in November and $8,300,342 in December, 1919. For the full year 1920, the preliminary returns placed the total number of failures at 8,831, as against 6,451 in 1919. The liabilities involved were $287,772,471, and $113,291,237 for 1920 and 1919 respectively. A great increase in both the number of failures and in liabilities occurred in each of the last two quarters for 1920.

The money market continued unchanged last week with call money at 7 per cent. Large sums were returned to the banks daily as unlendable. A slight easing occurred on Monday of this week, however, and call money loaned at 6 per cent for the first time since Dec. 21. Time money continued at the same rates quoted for the two previous weeks.

REVERE DENIES CHARGES

INDIANAPOLIS, Jan. 11—The Revere Motor Co. of Logansport to-day entered a general denial in Federal court in answer to bankruptcy proceedings instituted against it two weeks ago by Chicago creditors. Judge Anderson set the case for trial Jan. 18.

MEN OF THE INDUSTRY

Major Victor W. Page has resigned as managing editor of *Everyday Engineering Magazine* and technical editor of the Norman W. Henley Publishing Co., and has moved his consulting engineering offices from 2 W. 45th Street to 309 Lafayette Street, New York. He is now president and chief engineer of the Victor Page Motors Corp., which has been formed to manufacture and market a new lightweight car, equipped with a four cylinder air-cooled engine of his design.

W. G. Jarman, general manager and secretary-treasurer of the Hamilton Motors Co., manufacturers of the Panhard motor truck, Grand Haven, Mich., has resigned, taking effect immediately. Jarman prior to the Panhard connection was sales manager of the Jackson Automobile Co., prior to that Canadian manager for Briscoe, and earlier was connected with Maxwell-Briscoe and Ford.

A. Schroeder, Cleveland, was elected president of the Ohio State Rubber Tire Co. of Port Clinton, near here, Jan. 5. The other officers chosen are J. F. Langenau, Cleveland, vice-president; Harmon Hankammer, Port Clinton, secretary. The following constitute the board of directors: A. Schroeder, J. F. Langenau, W. S. Lee, Bellevue; E. P. Reichert and S. E. Gernerm, Port Clinton.

Daniel G. Thorne, formerly district manager for the Diamond T Truck Co., has joined the Republic Truck Co. and will have charge of sales to national buyers, such as oil companies and other organizations doing business in all parts of the country. This announcement was made by A. J. Whipple, general sales manager, who is here for the automobile show.

Thomas H. Bingham has been appointed production manager of the Matthews Engineering Co., Sandusky, Ohio, which is prepared to go into larger manufacturing schedules with the completion of its new factory additions. Bingham for the past five years has been general superintendent of the Akron works of the International Harvester Co.

R. Jackson Jones, European representative of the Traffic Motor Truck Corp., has returned to this country after a trip through all the countries of Europe. He reports that traffic dealers are optimistic over the future. The widespread use of trucks during the war has educated the public to their value.

Ludwig T. Kuehl, of Racine, Wis., has been elected a director and vice-president of the Northeastern Rubber Co., New York, succeeding George G. Bryant of Milwaukee. Richard G. Bryant of Racine is president and treasurer. Charles E. Davies has been elected a director and secretary.

J. H. Desmond for the past three years, district manager for the Hart-Parr Co., over their Canadian territory with headquarters at Regina has been called in to the factory at Charles City and placed in charge of salesmen in the field.

Lynn Harvey has been appointed manager of the new export department of the India Tire & Rubber Co. He was formerly assistant export manager for the Miller Rubber Co., and had also been connected with the H. K. Porter Co.

Dorsey W. Hyde, Jr., has left the transportation engineering division of the Packard Motor Car Co. to become assistant manager of the Civic Development Department of the Chamber of Commerce of the United States.

Forest H. Akers has been appointed assistant general sales manager of the Republic Truck Corp. For the past seven years he has been connected with the Reo Motor Car Co., latterly as general sales manager.

F. W. Potts, for several years northwestern district manager of the Republic Rubber Co., with headquarters at Minneapolis, has resigned, effective Jan. 15. No announcement has been made of his future plans.

Barney Oldfield, famous race driver who is now in the tire business, is one of the most interested visitors at the New York show.

H. L. Van Wyck, advertising manager for the Mitchell company, has resigned.

Pollak Makes Changes in Staff Organization

CHICAGO, Jan. 10—At a recent meeting of the Board of Directors of the Pollak Steel Co., D. E. Sawyer was again elected general sales manager for the year of 1921 and is located, as in the past, at the New York office of the company. S. K. Morrow, formerly manager of operations, is now manager of sales for the three plants, with the offices at Cincinnati works. C. G. Talbott, formerly assistant manager of operations is now manager of rolled products for the Marion plant.

A. C. Weihl, for several years superintendent of the Cincinnati plant, is now general works manager in charge of operations and production of the Cincinnati, Chicago and Marion plants. V. W. Prather, formerly cost auditor for the Cincinnati plant, is now general cost auditor of the three plants. R. A. Mitchell takes the position vacated by Weihl. J. H. Deickman becomes manager of materials and inspection of the three plants. W. P. Woods becomes auditor and G. H. Tallaksen, superintendent of the Chicago plant.

Sorenson Promotion Now Believed Certain

DETROIT, Jan. 11—Though no official announcement has been made of the appointment of Charles Sorensen to succeed F. L. Klingensmith as executive vice-president and general manager of the Ford Motor Co., there is no doubt here of the certainty of the move. The appointment is expected to be made this week, together with other changes to fill important positions vacated either through resignations or promotions.

Edsel Ford to-day said there was no truth in the rumor that W. G. McAdoo or W. C. Durant were to join the Ford organization.

HAVANA OFFICERS CHOSEN

HAVANA, Jan. 10—Samuel T. Tolon has been re-elected president of the Havana Automobile Dealers' Association, according to information reaching New York. With Tolon were named Francisco Pla as vice-president, E. W. Miles as treasurer, M. T. Vallin, assistant treasurer; Enrique Hemel, secretary, and J. E. Diaz, assistant secretary. The directors are Jose G. Lopez, J. M. Martinez, Gabriel Miguez, Octavia Longa, Ramon Fernandez, and Alejandro Rodriguez.

INDUSTRIAL NOTES

L. H. Gilmer Co., manufacturers of belting and woven products whose main plant is located in Tacony, Pa., has disposed of their Allentown plant; moving the machinery and equipment to their factory at North Wales, Pa., which plant has been expanded for additional equipment.

Dodge Brothers this week will pay a bonus to employees amounting to about $2,000,000 on a basis of 10 to 15 per cent of the wages earned during the year. Both office and shop employees will share the bonus, the practice of distributing which originated last year.

Gehl Mfg. Co., West Bend, Wis., maker of gas engines and ensilage cutters, resumed production during the week after being partly closed down to facilitate extensive improvements. A new gray iron furnace has been installed.

Speedograph Corp., Newark, N. J., has purchased a two-acre tract and four concrete buildings at Morris Plains, N. J., and by Feb. 1 expect to be in production of 100 instruments a day.

Latex Tire & Rubber Co. Fond du Lac, Wis., has broken ground for a 2-story factory addition, 60 x 80 ft., which will cost about $45,000 equipped.

Badger Mfg. Corp., Milwaukee, has leased a factory building in anticipation of a greatly increased demand for its product in the near future.

Martin Tire Corp., this city, which has up to this time been specializing on passenger car tires is planning to get into production on truck tire sizes.

Advance Rubber Co. has moved into its new plant in Brooklyn and is looking forward to greatly increased production in the spring.

Western Felt Works has completed its new factory buildings in Chicago and is preparing to go into production at once.

Hyatt Roller Bearing Co. will remain closed until Feb. 1 or later, according to business developments.

Ladish Drop Forge Co., Milwaukee, expects to get back to normal production by Feb. 1.

Duplex Truck Surplus $249,276 for Year

DETROIT, Jan. 10—Duplex Truck Co. at Lansing, Mich., reports current assets totalling $1,137,851.86; current liabilities of $538,436.29, and surplus of $249,276.25 for the year ending Oct. 31. The management also has charged off $200,000 depreciation.

In a letter to stockholders, Pres. H. M. Lee said the credit stringency hit the truck business worse than any other due to the fact that it essentially is a credit business, practically 95 per cent of all truck sales being on a time basis. "With banks refusing to discount paper taken by dealers, sales stopped automatically," he said, "because few dealers were sufficiently financed to be able to carry the customer's paper."

Duplex earnings during the first of the year, Lee said, were very satisfactory and demonstrated the force of the company's costs and selling prices and indicated that with ten or twelve consecutive months of normal business, the company could show satisfactory earnings.

Calendar

SHOWS

Jan. 15-22—Philadelphia, Annual Automobile Show, Philadelphia Automobile Trade Ass'n.

Jan. 17-23—Milwaukee, Annual Automobile Show, Milwaukee Automotive Dealers' Ass'n.

Jan. 22-27—San Francisco, Second Annual Pacific Coast Automotive Equipment Exposition, Auditorium.

Jan. 22-29—Baltimore, Annual Automobile Show, Baltimore, Automobile Dealers' Ass'n, 5th Regiment Armory, J. C. O'Brien, Mgr.

Jan. 22-29—Cleveland, Annual Passenger Car Show, Cleveland Mfr's & Dealers' Ass'n, Wigmore Coliseum.

Jan. 22-29—Montreal, Annual Automobile Show, Montreal Automobile Trade Ass'n, Motordrome Bldg.

Jan. 29-Feb. 4 — Chicago, National Passenger Car Show, Coliseum, Auspices of N.A.C.C.

Jan. 31-Feb. 5—London, Ont., National Automobile Show of Western Canada, London Chamber of Commerce, Armouries, T. C. Kirby, Mgr.

Feb. 5-12—Minneapolis, Annual Automobile Show, Minneapolis Automobile Trade Ass'n.

Feb. 7-12—Columbus, National Tractor Show, Columbus Tractor & Implement Club, Ohio State Fair Grounds.

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n, Armory, Arthur Fifoot, Mgr.

Feb. 12-19—Kansas City, Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—St. Louis, Annual Automobile Show, St. Louis Automobile M'f'rs & Dealers' Ass'n, Robt. E. Lee, Mgr.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, sec'y.

Feb. 21-26—Salt Lake City, Annual Automobile Show, Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Jan. 22-29 — Colombo, Ceylon Motor Show.

Feb. 7—Delhi, India, Delhi Motor Show.

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

CONVENTIONS

Feb. 2-4—Chicago, First Annual Meeting, Automotive Electric Service Assn. Hotel La Salle.

May 4-7 — Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

30 Organizations Back Uniform Vehicle Act

WASHINGTON, Jan. 12—Principles of a uniform vehicle act were adopted here to-day by the National Conference on Highway Traffic Regulations, and there was practically no variation from the proposed uniform vehicle law adopted last year by a committee representing the National Automobile Chamber of Commerce, American Automobile Association, American Association of State Highway Officials and the Highway Industries Association. The acceptance of these principles virtually means that instead of six national organizations, there will be more than 30 organizations pledged to support the underlying principles in an effort to have them placed on the statutes of all states.

At the suggestion of Harry Meixell, representing the National Automobile Chamber of Commerce, National Automobile Dealers Association, Motor & Accessory Manufacturers Association and Rubber Association of America, the conference did not specify any weight limitation.

On the objection of Meixell in behalf of the automotive organizations, the conference reconsidered its vote on mandatory stops at crossings and refused to include it in the declaration of principles.

Bureau of Mines Drops Gravity Specifications

WASHINGTON, Jan. 12—Specifications for petroleum products have been completed by the Bureau of Mines. The report, made public to-day, shows more definite standards of testing for automobile fuels and oils. Most of the suggestions of the Society of Automotive Engineers were incorporated.

The old gravity specifications for fuel oil have been completely eliminated. The viscosity requirement has been set for each grade of fuel oil and the Saybolt "Furol" viscosimeter adopted for testing all fuel oils was purchased by the Federal Government.

Lubricating oils specifications are practically unchanged, but several new grades have been added.

"Old Timers" to Hold Chicago Show Dinner

NEW YORK, Jan. 12—At a meeting of the Advertising Managers Council of the M. A. M. A., Ralph Leavenworth speaking for the Standard Parts Co., said that the Old Timers Club had enrolled more than 6,000 members. He said that the idea of this club was originated by Jim Braden, former advertising manager of that company, and no one had expected the distribution of badges to be taken so seriously. His plan was that this idea should become so widespread that it could be taken over by those he had enrolled.

Acting on this suggestion, several of those enrolled met yesterday at the Vanderbilt Hotel and formally decided to announce a dinner to take place during the Chicago show. All "Old Timers" will be welcomed at this dinner. At that time, Richard Kinnerdall, chairman of the nomination committee will announce the following nominations for office:—president, Albert Champion; secretary, F. Ed. Spooner; treasurer, Harvey Firestone.

Big British Companies Overcome Difficulties

LONDON, Jan. 10—No acute financial distress is anticipated for any of the important British automotive companies despite the general money tightness and vehicles awaiting sale. Creditors realize that a bigger loss would follow forced closures and they have confidence in the inherent stability of the trade.

Dunlop Rubber Co. has declared that negotiations concerning the company's American affairs may last another week. Its report for the financial year is expected this month. Stockholders have been cautioned by the company not to pay attention to adverse reports on Dunlop.

Briton Motor Co., Wolverhamton, one of the oldest British car manufacturers, has shown itself to be suffering from the financial stringency, but declared it to be only temporary. Orders are reported for $1,500,000 worth of cars on which deposits have been paid. Trade liabilities are given as $150,000 to Nov. 30, and bankers hold debenture securities for $200,000. It is proposed to liquidate the indebtedness by monthly installments beginning in March.

If this proposal fails the alternative will be a forced realization by the debenture holders.

VOL. XLIII INDEX

The index to Automotive Industries, Vol. XLIII, which comprises issues for the second six months of 1920, will shortly be off the press. It will be mailed without charge to subscribers who make a request for it.

Progress in Fuel Matters Features Annual S. A. E. Meeting

Much interest attaches to developments in fuel research of past year. Chassis session also brings out much discussion. Aeronautic sessions are well attended, while those devoted to body engineering and highways also prove highly successful.

By Herbert Chase

THE annual meeting of the Society of Automotive Engineers, just completed in New York, is regarded by many members of the organization as the best in the history of the Society. All of the sessions were well attended and the plan of holding simultaneous sessions on subjects not closely related proved very successful.

The fuel session, being as usual the most important, was the best attended, and those who were present could not have failed to carry away much useful information or avoid the conclusion that the persistent consideration of matters relating to fuel and its proper utilization is beginning to show results at least in the improvement of many of the automotive vehicles now being designed and produced.

There is, of course, a long distance still to be covered before it can be said that the average automotive vehicle is using fuel in a thoroughly efficient manner, and there still remains the stupendous problem of getting higher average efficiency in the operation of the nearly nine million automotive vehicles in use to-day. This, indeed, is a problem worthy of the best efforts of the most capable engineers, yet receiving scant consideration. As pointed out by speakers at the meeting, the average automotive engine now in use not only runs throttled a large percentage of the time—a condition under which high economy is impossible—but less than 75 per cent of the fuel entering the cylinder is burned in the average case, as definitely proved in one paper covering tests of a full hundred passenger cars and trucks. This waste of fuel is just as real as if 25 out of each hundred gallons of gasoline put into the car or truck tank was allowed to leak out, and is far more harmful than if so lost, for it results in many engine troubles, yet little or nothing is done to check the loss though it might be well nigh eliminated if car manufacturers were sufficiently interested to supply modern manifolds and carbureters and see that the service station and user are acquainted with the facts and educated to the importance and feasibility of bettering the fuel utilization of the car now in service.

The most discussed and perhaps the most valuable paper presented was that entitled the Fuel Problem in Relation to Engineering Viewpoint, by A. L. Nelson, chief engineer of the Premier Motor Corporation. The stated object of the paper was to get the engineer to take a broader viewpoint of the fuel situation and not to take the position that things which heretofore have not been commercially successful or feasible are by no means impossible of attainment. The paper, which will appear in an early issue of AUTOMOTIVE INDUSTRIES, should be instrumental in attaining this commendable object, but it goes much further than its title indicates in a most original and instructive presentation of data which no engineer who wishes

to be conversant with promising methods of improving car performance should fail to acquaint himself with. The author shows in the first place how small a proportion of the available power of the engine is required to propel a car at moderate speed on the level road, and points out how low a power factor with consequent low fuel economy results. It is then shown how economy and performance can be greatly increased by increased compression ratio, made feasible by a very late closing of the inlet valve. The effect of gear ratio on economy is also set forth and some new designs of piston and inlet manifold are described.

In discussing this paper C. P. Grimes laid stress upon the need for bettering the load factor as a means of securing better economy and briefly outlined tests he had recently made which showed that greater economy results from carrying a greater spark advance than is commonly employed under part throttle conditions. He suggested the need for some interconnection between throttle and spark advance mechanism when the latter is automatic as it then must be set to properly function at full loads when at the same speed and part load a greater advance can be used to advantage. H. L. Horning, among others, commended Nelson for the valuable paper he presented. He suggested that less valve lift than was employed by Nelson would have resulted in greater turbulence in the charge with good effect.

Fuel Waste in Present Cars

An item not on the program which proved of considerable interest was a report of tests conducted by the Bureau of Mines for the purpose of determining the percentage of unburned products in the exhaust of a large number of cars selected at random and tested under normal operating conditions in precisely the same state of adjustment (or lack of adjustment) in which they run in normal use. This report showed that in the average case the exhaust contained only 9 per cent of carbon dioxide, completely burned carbon, while the average percentage of carbon monoxide (partly burned carbon) was seven, and the unburned hydrogen and hydrocarbons was over 3 per cent. Not a car was found in which more than 95 per cent of the fuel was burned, and as previously stated the average percentage burned was under 75. This means that the average car is using an effective air to gas ratio of only 12 to 1, a ratio of 14 to 1 is the theoretical ratio for complete combustion, and 16 or more to one is usually required for maximum efficiency. In other words, the average user employs a much richer mixture than is necessary, though in so doing his fuel bill is about one-third higher than necessary and troubles from carbon deposits and crankcase polution, to mention only two evil effects, are encouraged. Until steps are taken to remedy this condition service problems will continue to multiply and the fuel problem will continue to grow more menacing.

In discussing this Bureau of Mines report Elmer Sperry drew attention to the fact that not even a trace of carbon monoxide was found in the exhaust gas of several Diesel engines in tests he had directed, although the fuel commonly employed is far less volatile than that used in conventional automotive engines. He spoke also of the apparent dread which the average engineer has of attempting to use high compression in engines, in spite of the fact that this involves little more than the addition of about three piston rings. A piston so fitted will, he said, fall of its own weight through the cylinder, and have little more friction than ordinary pistons.

C. F. Kettering's talk was similar in many respects to those he has given at past meetings of the Society, although he freely admitted that theories he had formerly evolved had been modified in many cases as new information had been accumulated. He feels that the fuel problem is beginning to be appreciated both by the automotive and fuel industries. He drew attention to the general misconceptions which a lack of understanding of terminology have brought about and said that it aids greatly in the understanding of combustion phenomena to remember that changes in temperature due to addition or subtraction of heat are simply interpreted as meaning increase or decrease in the velocity of the molecules of the substance heated.

Frank A. Howard, development manager of the Standard Oil Co. of New Jersey, in his paper on the Volatility of Internal Combustion Engine Gasoline first defined the term "gasoline" as "the cheapest petroleum product acceptable for universal use as a fuel in the prevailing type of internal combustion engine." He then showed the physical meaning of the term volatility, the vapor tension method of measuring it, laid stress on the fact that inherent volatility is dependent upon time, surface and heat. He commended the use of so-called hot-spot devices for adding heat to the fuel entering an engine and made it clear that heating the air only is not effective for the reason that air is a poor conductor of heat and therefore will not bring about vaporization of the fuel in the limited time available. The hot-spot will do this if so arranged that the fuel particles are thrown out of the insulating air stream against it and manifold "condensation" is impossible under the average manifold temperature prevailing because it is physically impossible for any vapor to condense when its partial pressure is lower than the vapor pressure of the liquid itself at that temperature.

Howard believes that the hot-spot, when properly designed, is an effective and simple solution of the problem, that it should be incorporated in new designs, and that it will lend itself to attachment in existing engines.

Howard, who was the only speaker who could be said to represent the point of view of the fuel industry, expressed himself as being pleased with the indications of progress in solving the fuel problem which were brought to light during the meeting.

Flame Movement in Closed Cylinders

The paper on Flame Movement in a Closed Cylinder by C. A. Woodbury was read in the absence of the author by his assistant, Mr. Lewis, and developed much useful information which supplements, and in part corroborates the work done by Prof. H. B. Dixon in England. Dr. Woodbury plans to continue this work and report upon it further at later meetings of the Society. To date the fuel used has been a fixed gas, acetylene, but it is the plan to later experiment with more complex fuels, such as are used in internal combustion engines. Results thus far appear to indicate that true detonations do not take place in cylinders of the size employed in automotive apparatus, but final conclusions in this regard are reserved pending the completion of further tests.

In a paper entitled Air Temperature Regulation Effects on Fuel Economy, R. E. Fielder of the Fifth Avenue Coach Company, the thermostatic device designed for use on buses operated by his company for controlling the temperature of air entering the carbureter. With this device it has proved possible to make an average saving of about 8 per cent, which means much when it is considered that the company uses several million gallons of gasoline each year, the fuel bill constituting the second greatest item of expense. The temperature control device is reported to afford the greatest possibility of saving in fuel of any of the numerous fuel devices tested.

The only other paper read at the fuel session was that

by Dr. H. C. Dickinson of the Bureau of Standards in which he gave a résumé of certain research work relating to fuel which the Bureau has been conducting. This work included some studies of conditions known to aggravate the tendency of an engine to knock. In order to prove that the knock is due after all to an aggravated piston slap, a piston with excessive clearance was tried, and it was found possible to readily distinguish between knock due to combustion phenomena and piston slap.

Other tests involving the use of one or two spark plugs used separately or together were conducted, and it was found possible to bring about conditions in which firing from one plug would cause a knock when firing from two plugs would not do so and vice versa. The reason for this is not yet apparent, but it is thought probable that the knock can be controlled by accurate timing of the center of the explosion. It has been noted that pressures in excess of 1000 lb. per square inch may result from the knock phenomenon, and that the latter is invariably accompanied by a sudden rise in temperature of the jacket water.

Thomas Midgley, Jr., stated that some believe that the temperature occurring at the time of the knock may be sufficient to convert carbon into the gaseous state. In any case quartz cylinder windows have enabled observation of the fact that an extremely brilliant light accompanies the knock. Spectrum analysis of this light reveals a green line thought, but not definitely known, to indicate carbon gas. Mr. Weinberg questioned this, stating that the highest temperatures attainable in a carbon arc in vacuum are not accompanied by gasification of carbon. He cited experiments that he has conducted on a 5⅞ by 6-in. air-cooled engine developing 35 hp. at 900 r.p.m. This engine cools very well, he said, when the spark plug is placed near the inlet valve, but when placed opposite the exhaust valve it is impossible to keep the engine cool.

H. L. Horning, in closing the discussion on fuel, cited the need for tests that would enable a measure of carbureter efficiency independent of engine performance, and outlined a test that he believes will give the desired result. He spoke of the plan for co-operation between the S. A. E., the American Petroleum Institute, the Bureau of Standards and the Bureau of Mines, and indicated that plans for financing research work bearing on the fuel problem at the laboratories of the two organizations last mentioned are being formulated and will shortly be announced.

The Chassis Session

By P. M. Heldt

H. M. CRANE presided at the chassis session, which was held in the Auditorium of the Engineering Societies Building, and was well attended. In opening the meeting Mr. Crane said the principal object was to discuss various questions which had come up from time to time in connection with the work of the Fuel Committee. Questions were constantly being asked as to why we burned so much fuel per passenger mile or per ton-mile. The petroleum industry had taken a certain view regarding the small car which called for comment. Comfort and speed were factors which could not be neglected in passenger-car design, even if somewhat more fuel had to be burned in order to provide them. We could not rationally ask the public to ride in open cars without top or windshield to save fuel.

We were often asked why we were using low-geared cars. The answer was that the public wants them. Possibly the public wanted low-geared cars because of the difficulty of gear changing. Unfortunately, the design of the present type of engine was such that if we cut down its power we also reduced its economy. The speaker said he had been told that on a flat stretch the most economical way to drive a car was to accelerate to full speed as rapidly as possible and then let the car coast with the engine cut off.

One reason for poor fuel efficiency was defective brake rigging, with the result that the brakes were constantly dragging, there being no means for rapidly adjusting them. Defective gearbox and axle design were other causes of low fuel efficiency. The housings of these parts were often of such design that the parts could not be lubricated by oil, and grease was generally a poor lubricant. In cold weather the grease becomes very stiff, so that a large amount of power was required to turn the gears, and everyone was familiar with the fact that occasionally it was impossible to shift the gears at all on a cold morning.

A paper on a Suggested Rating Rule for Racing Cars was presented by Mr. Crane, of which he gave a brief abstract only. Reference was made to the present racing rule, limiting the piston displacement of the engine to 183 cu. in. and it was pointed out that the piston displacement limit had led to such developments as enormous valve areas, huge inlet pipes and carbureters, extreme valve timing, and very light reciprocating parts. However desirable these features might be for racing purposes, they were undesirable in commercial engines. Those first mentioned made good performance at moderate and low engine speeds impossible with the present type of fuel, while the very light pistons used could not be expected to give either reasonable wear or proper control of lubrication in commercial service.

Mr. Crane's suggestion was to use a rule whereby cars would be rated in accordance with the piston displacement per mile actually used by them. Such a rule would involve rear wheel diameter and gear ratio, as well as the piston displacement of the engine. He pointed out that racing is very expensive, and expressed the opinion that such a rule would be of greater help in developing commercial design of passenger cars and trucks by enabling engineers to get some really valuable lessons from racing.

The second speaker was J. G. Vincent, who spoke briefly on Economy and Performance Demands. Mr. Vincent said that the average user, when thinking of economy, thought only of gasoline economy. However, the gasoline bill was not the chief item of expense, as a rule. Engine design was limited by the demand for performance. An acceleration of from 5 to 30 m.p.h. in anywhere from 12 to 14 seconds was generally desired. The engineer then had three choices: He might select a high speed engine with a gear ratio of about 5½ to 1, a medium speed engine with a gear ratio of about 4 to 1, or a low speed engine with a gear ratio of 2½ to 3. The speaker did not believe that so far as the engine was concerned, there was any great difference in respect to thermal efficiency because the larger engine would

have to be operated at a lower compression pressure.

Mr. Vincent expressed the view that entirely too much importance had been attached to the effect of the throttle on economy, and not enough to the friction of the engine. Probably everyone had tried the experiment of gradually reducing the amount of lubricant supplied to the engine, and he for one had been surprised at the small amount of oil to the cylinder that he "could get away with," but in thus cutting down the lubrication he had experienced other troubles which he had not looked for, such as increased crankcase dilution. In the matter of tires, he believed there was such a thing as oversizing, as well as undersizing, and the happy mean was the best. It was not possible to lay down rules as to how big a car to build, because different people demanded different sizes. Service costs were in proportion to simplicity, reliability and accessibility, which features he did not pretend to have given in the order of their relative importance. The automobile designer would do well to take out a sample car and test it on the road for a few months, taking care of the car himself, before turning it over to the factory. He would often be surprised what a number of parts had to be taken off before he was able to get at any particular part that needed attention. If there should come about a great change in the matter of performance requirements, the four-speed gearbox would get more consideration again.

Chassis Design for Fuel Economy

A. L. Putnam presented a paper on Chassis Design for Fuel Economy. Mr. Putnam stated that engines are now so reliable that they require very little attention, hours being usually spent on other parts where only minutes are spent on the engine. He wished to call attention to some of the losses in other parts of the chassis. Following are extracts covering the main points made in the paper:

The anti-friction bearings give very little chance for any considerable improvement. But the practice of using in the transmission and rear axle a very heavy grease which solidifies at even a cool temperature is far from economical from the standpoint of fuel economy and efficient lubrication. This is particularly the case when the car is frequently stopped and started and used intermittently in very cold weather. It is now perfectly possible to make and install gears which will pass as to sound even if not smothered by "dope." It is also possible to construct properly vented transmission cases and differential housings which will hold thin oil with even less leakage than we have at present with heavy oil.

The great congestion of traffic in cities has brought about a very common custom of insistence on a brake adjustment which gives instant action with a very small pedal movement. The external-band brake is a very poor instrument to fulfil this condition. It is virtually impossible as a matter of common practice to adjust it closely enough to suit and still not drag some. As the quick brake must be had at any cost, the larger number are dragging. A dragging brake which does not heat enough to call attention to itself by developing excessive heat at a moderate speed still has a marked effect on the position of the throttle and is the cause of wasting much fuel. Brakes are pulling from a mere fraction to several horsepower per pair out of the majority of cars equipped with them. The internal-expanding type of brake is much better adapted to extremely close adjustment without dragging and the heat it generates expands and contracts the drum in the right direction with relation to the shoes instead of the wrong direction as in the case of the external-band brake.

The excessive amount of motion between the engine and the axle, of course, causes a loss of power and fuel in a minor degree due to joint angularity which produces wear; it takes power to produce wear. I think that this excessive amount of movement, no matter how smoothly accomplished, is not, strictly speaking, a comfortable one for the passengers, and know that it is very fatiguing for the driver, increasing greatly the strain of guiding the vehicle.

Unsprung Weight

As the weight of the axle and springs is on the average about one-quarter of the total weight, these parts are able to cause considerable disturbance in the smooth operation of the vehicle. This fact is, of course, so generally appreciated that many serious endeavors are made to reduce appreciably the weight of these unsprung parts and by so doing decrease the effect of their action and reaction. These efforts undoubtedly have good effect when they are carried far enough to make an appreciable change in the proportion of sprung and unsprung weight.

The pneumatic tire is one of the main factors in the success of the passenger automobile. If this tire is such a good thing, why not have a little more of it? Why not give it a larger opportunity to show its worth and itself absorb a larger proportion of the shocks, and give better traction?

In fact it is perfectly possible to carry this idea far enough to eliminate the springs entirely and simply provide for the horizontal displacement of the front wheels with relation to the rear pair. When this is done the unsprung weight factor will have disappeared, as all the weight is sprung weight and completely tied together without movement. The wheels move with the body and the body with the wheels.

At present we seem to be accepting as gospel the statement that the present tire sizes as put forward are the last word as regards pneumatic-tire equipment, when a little thought and even less science can prove them as only the beginning of the real use of pneumatic tires.

Mr. Crane said he was glad Mr. Putnam had put so much emphasis on the tire problem. The fabric tire was inherently a shock absorber, and that was the reason of its shortness of life; it absorbed the energy of the shocks and that destroyed it. The tire companies in their literature had not taken full advantage of the possibilities of the cord tire.

Mechanical Losses

Next was read a paper entitled: "Mechanical Losses an Economy Factor," by Prof. Wm. T. Magruder of Ohio State University. Prof. Magruder said that tests of engines and materials had become common, and that greater attention must now be given to the smaller parts of the motor car. We could hardly expect private laboratories to make public the results which they had obtained at great effort and expense, and the general public must look for such informaton to the Bureau of Standards and to the several engineering laboratories conducted in connection with state universities and other institutions. Figures were given for the friction horsepower of the Ford engine at normal speed, and this was said to be approximately equal to the power required to drive an automobile at moderate speeds. How to reduce this friction horsepower was a problem that called for experimental investigation. The temperature of the jacket water had an important influence on the operation and economy of an engine. Intense cooling increased the power and reduced the specific fuel consumption, both with gasoline and kerosene. Prof. Magruder described the testing facilities at Ohio State University, and some of the methods followed in making power and

efficiency tests of engines, transmissions and complete chassis.

W. P. Kennedy presented a brief note descriptive of three light German cars, on behalf of Col. A. J. Slade, who was a member of the U. S. Armistice Commission and who, upon his return to the United States, brought along samples of the cars referred to, a Benz, a Wanderer and a Mathis. Recently experiments had been conducted with these cars to see whether a car of the Wanderer type, for instance, would not be more economical to maintain than heavy motorcycles in the mail service. Mr. Kennedy said that in case the design should be found suitable, it would have to be somewhat Americanized by increasing the tread from 48 to 56 in. and by making various parts more accessible so as to facilitate repairs.

C. W. Spicer presented a paper on Torsional Strength of Multiple Splined Shafts. Tests were run on 15 carefully machined shafts, of the dimensions shown in Fig. 1, there being not more than 0.0005 in variation from the diameters shown. The shafts were carefully heat treated, each specimen being checked by Brinell tests at the ends and by scleroscope tests throughout its length, the Brinell hardness lying between 220 and 235 and the scleroscope hardness between 38 and 43.

It will be noticed that the small diameter of shafts Nos. 11 to 15 lies between the large and the small diameters of shafts Nos. 6 to 10. This diameter represents a shaft which, according to one authority, is hypothetically equivalent to the splined shaft in torsional strength. Mr. Spicer's tests disproved this assertion.

The results of individual tests of the five specimens of each group were very uniform. The curves shown in Fig. 2 represent the average of the five shafts in each group, and are self-explanatory. Curve A is the plotted average of shafts Nos. 1 to 5. Curve B is curve A corrected for a diameter equal to the small diameter of shafts Nos. 6 to 10. Curve C is the average of shafts Nos. 6 to 10, and curve D is the average of shafts Nos. 11 to 15.

The position of the letters a, c, d also indicates the location of the so-called Johnson elastic limit; that is, the point at which the unit increment of deflection per unit of load increase is 50 per cent greater than at the beginning.

Comparing curves B and C it will be readily seen that a splined shaft of the dimensions given has a torsional

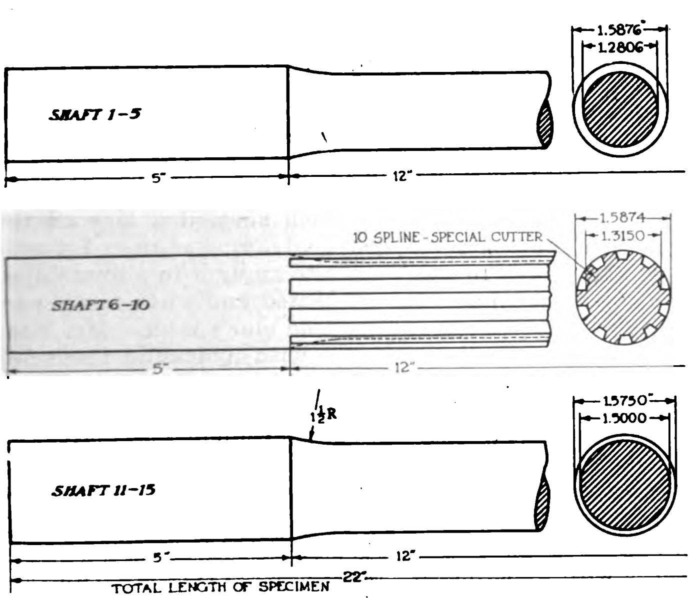

Fig. 1—Dimensions of test pieces used in splined shaft torsion tests

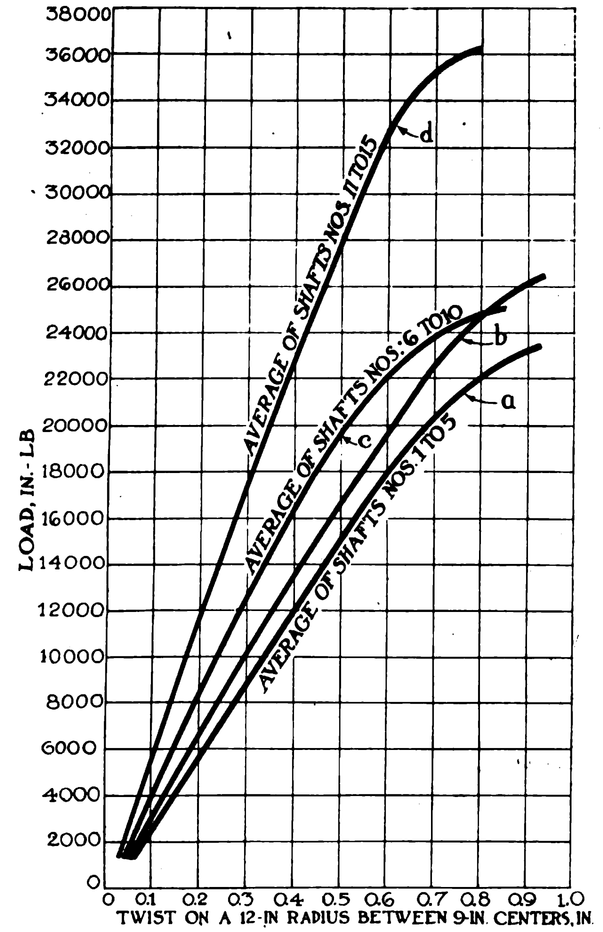

Fig. 2—Curves showing results of splined shaft tests

elastic limit of approximately 18 per cent less than a full round shaft of a diameter equal to the small diameter of the splined shaft. The elastic limit of the hypothetically equivalent shaft is very much higher.

A paper on a New Principle of Engine Suspension was presented by S. E. Slocum, Professor of Applied Mechanics at the University of Cincinnati. The method referred to consists in mounting the engine or powerplant upon a sub-frame or cradle, which is rigidly supported upon a trunnion at the middle of a cross member of the frame at one end, and resiliently supported on the main frame on both sides at the opposite end. Prof. Slocum said that most of the vibration in a motor car was due to synchronism between the natural period of vibration of the complete chassis and the operating speed of the engine. By mounting the engine as described, it would not only have a three point support, but within certain limits it would have freedom of motion about a fixed point. The engine had three degrees of freedom and it was possible to absolutely control the period of vibration. By properly designing or adjusting the resilient supports, which were shown in the form of coiled springs, it was possible to change the period of vibration so as to prevent any possibility of its synchronizing with the natural period of the chassis.

J. G. Perrin, who had been abroad recently, attending the London show, spoke briefly on light cars in Europe. He voiced the opinion that we did not have very much to learn from European engineers in the matter of securing economy. Abroad they obtained economy by using very small cars, which would not be practical here, at least not so long as we failed to get over our mania of doing everything on the high gear. They secured light weight by making their cars small. They used smaller

gear ratios, and we all knew that that made for fuel economy. The only example of advanced design that he saw was the Ricardo engine, which he described briefly. All the small cars being brought out in England had engines of only 11 to 12 h.p., and one reason for this low power was that the British Government had recently imposed a tax of one pound sterling per horsepower. In judging European fuel economy figures, it must be kept in mind that they are based on a somewhat better grade of gasoline than we were using, and, of course, it must also not be lost sight of that the Imperial gallon is considerably bigger than the U. S. gallon.

One speaker said that he had had experience in France with both the Wanderer and the Baby Peugeot. Both of these cars were equipped with 4-cylinder, 60 x 90 mm. (2.36 x 3.54) engines. The one original feature on the Wanderer was a transmission case of pressed steel. On the whole the Baby Peugeot showed much the better performance. On one occasion he drove it at an average speed of 28 m.p.h. continuously for over 2 hrs., with a fuel consumption of 7 liters per 100 kilometers, which is equivalent to nearly 34 miles per gal. Both the Wanderer and the Baby Peugeot were magneto-equipped. The Wanderer had a silent camshaft drive, while the Peugeot had a direct drive on both the second and third speeds, the second speed reduction being 7 to 1 and the third speed, 3½ to 1. Both of these cars weighed in the neighborhood of 1300 lb.

Efficiency of Pneumatic Tires

Mr. Manly asked Mr. Vincent what was the actual efficiency of the pneumatic tire. When the A. C. A. erected its clubhouse it installed a chassis testing dynamometer in its laboratory, and tests made on this dynamometer showed that a great amount of power was lost in the tires. In the case of one particular car, this loss amounted to from 36 to 45 h.p., and the results were very disappointing to the manufacturer. Mr. Manly said his reason for bringing up this matter was because in 1896 he had made some tests on the efficiency of bicycle tires in collaboration with Prof. Carpenter at Cornell University, and these tests indicated very low efficiency, the efficiency, moreover, being in inverse proportion to the wall thickness. Mr. Clayden said that the testing apparatus formerly installed in the A. C. A. laboratory had been transferred to Yale University, New Haven, Conn., and was now in charge of Prof. Lockwood, who had given some figures regarding the losses in pneumatic tires in a paper presented before the Philadelphia Section of the Society.

Mr. Manly said one thing he wanted to bring out was that a tire was very much more efficient when highly inflated, to which Mr. Crane replied that the efficiency also depended upon the flexibility of the casing. The power loss in cord tires varied between 20 and 30 per cent, while that in fabric tires amounted to considerably more.

Mr. Williams said it would appear, now that cord tires had come into extensive use, that it ought to be possible to make tires very much larger in width and with thinner walls, and at the same time use lower inflation pressures. Mr. Anglada said that if springs were to be dispensed with, it would be necessary to use pneumatic tires about 12 in. in width. In Buffalo recently he had seen a 12-in. tire on a motor truck burst, and the truck turn over as a result, and the same would undoubtedly happen if tires of such size were fitted to passenger cars.

F. E. Watts said that the published results of the French fuel economy contest showed that whereas the French cars were groomed to the highest pitch and handled with great skill, the American cars were poorly handled. He thought if the American cars had received treatment equal to the French, they could have done substantially as well. The French were getting more miles, but not more ton miles per gallon.

O. A. Malychevitch said that one difference between French and American practice was that, whereas in this country cars were generally completely designed by factory engineers, in France many cars were designed by independent engineers. After the design of the car was completed, it was passed on to the factory production specialists, who then worked out the production problems. This, he said, was one reason for the better economy of the French cars. H. M. Crane pointed out that an economy contest, as usually conducted, was a very inconclusive affair, for the reason that many expedients were resorted to in order to reduce the consumption that the ordinary driver would never think of in regular use. He mentioned particularly one car with which he was familiar, which won an economy contest some years ago. This had a special rear axle reduction of 1½ to 1, was equipped with silk cord racing sulky tires, was lubricated throughout with light machine oil, had a special high compression engine, and was lightened in many ways.

Low Mechanical Efficiency at Low Loads

H. L. Horning dwelt on the low mechanical efficiency of the gasoline engine at the loads usually carried in car operation. He said that the friction between the piston and the cylinder walls accounted in many cases for 50 per cent of the indicated horsepower, and he felt that there was much opportunity for reducing this loss of energy.

Prof. Berry said he would not like to have the idea spread that economy contests are of no value. He would like to see the S. A. E. or some other body hold a yearly contest of that kind, and to make it of practical value, the rules should be so drawn that it would be required to meet certain performance requirements before the economy contest, and let the adjustment of the car remain the same. H. M. Crane said he hoped Prof. Berry's suggestion would be taken up by the proper people and a suitable set of rules be worked out.

Mr. Wolf asked Dr. Slocum why the fixed point in the new chassis suspension described in his paper was located at the rear end of the engine. The answer was that in most cars already built it was easiest to place it at the rear end, but in new cars it could be placed at the front end just as well.

Hydraulic Transmissions

Mr. Davids wanted to know whether the difficult gear changing, to which reference had been made in one of the papers, could not be overcome by the adoption of hydraulic transmission. Mr. Williams said he knew of one hydraulic transmission which originated in Minneapolis some 15 years ago, which showed a loss on the testing stand of only 15 per cent. It was then brought East and an attempt was made to apply it to automobiles, but it was found that the oil heated and when metal particles got into the oil they caused much wear. Mr. Manly said he had had experience with hydraulic transmissions extending over a long period, and that such transmissions were successfully used for operating gun turrets on battleships, in which service they proved very efficient. He did not expect to see hydraulic transmissions applied to passenger cars, as they were too heavy, but for commercial vehicles they were giving satisfactory results.

A paper by D. McCall White, on Modern Chassis Construction, could not be presented, owing to the absence of the author and the lateness of the hour.

The Aeronautic Engineering Session

By J. Edward Schipper

COMMERCIAL aviation is about as highly developed as the art of aviation, if the impression conveyed by the aeronautic engineering session of the Winter S. A. E. meeting is correct. We are about to witness the dawn of some highly important developments in the art due to the discovery of new thick wing sections which offer great structural as well as aerodynamic advantages. Because of the high lift-drift ratio of these new sections it will be possible to carry greater loads on lighter weight planes with smaller engines, and consequently to operate at higher efficiency.

From a development standpoint the engine is ahead of the plane. In fact, from the opinions of those presenting papers at this session it is unnecessary—or at least should be unnecessary—to use the highly refined products for commercial aviation that we used during the war. Grover C. Loening stated in his talk that commercial aviation had been set back more than ahead by the war time developments. It is the general consensus of opinion that it should be unnecessary to use engines weighing around 2 lb. to the horsepower, and that engines of from 3 to 5 lb. per horsepower are sufficiently light with the new wing developments, the additional weight in the engine going into reliability, endurance and economy in manufacture.

F. W. Caldwell, who spoke on propellers, told of some very interesting and important developments in new propeller materials. The bakelite propeller in his opinion is about the most valuable type that we now have on account of its freedom from the bad effects of weather and its ability to resist chipping in striking rain. He also spoke very favorably in regard to some of the specially constructed steel designs which have been recently put out. Like other propeller men he was enthusiastic over the prospects opened up by the reversible propeller both for military and commercial purposes.

For commercial purposes it makes it possible to use planes that have high landing speeds, the retarding effect of the propeller being sufficient to check the run of the plane after alighting in a very short distance. This, of course, permits the use of machines for commercial purposes which have very high air speeds, making them more economical of operation, capable of carrying greater loads per engine horsepower besides being a factor in the saving of time for transporting freight and passengers. For military use, the reversible propeller opens up the possibilities of a great many new maneuvers outside of being able to land in restricted fields or, in the case of the navy, on ship deck platforms.

C. D. Hanscom presented a highly technical paper on the subject of airplane wings, dealing with some of the new sections which have recently been worked out in the various laboratories. He stated that the possibilities of thick wing development have not even reached their infancy. He showed a number of slides of the new wing sections, the best having an L/D of 14.2. In the discussion, however, a section was mentioned without any details being disclosed with an L/D of 21.8.

Speaking of front and rear flaps, Hanscom stated that they were not of great benefit except at high speeds. He said that the U. S. A-27 section with a 10 deg. flap at the leading edge and 5 deg. at the trailing edge gives very good results at high velocities. A point which was made very apparent in his talk is that a slight modification of the wing curve causes tremendous variations in the characteristics. This was brought out graphically in several instances by showing the wide variation in characteristic curves due to very slight changes in section contour.

Major T. H. Bane was unable to be present, but a résumé of military progress was given by a brother officer. This consisted practically entirely of slides and some very interesting moving pictures of the latest army parachute developments. An astonishing number of jumps have been made without accident, and from the examples shown no difficulty whatever is being experienced in making successful descents. Fireproof gasoline tanks covered with a coat of live rubber are being worked on and are giving promise of very successful results in preventing leaks from holes made by the various kinds of ammunition now in use.

The Commercial Aviation Session

By Herbert Chase

GLENN L. MARTIN presided at the commercial aviation session and presented the first paper. He spoke of the progress of aviation in Europe, mentioning in particular the regularity of the Paris-London service, which has been carried on during the past year with only four interruptions chargeable to defects in the machines. He cited also the efficiency of the forest patrol, in which aircraft have been used to splendid advantage. He called attention to the fact that the modern plane will fly in any weather, fog and darkness being the only hazards not yet completely overcome. He urged the construction of more air terminals and favored the Federal control of aircraft, including licensing of pilots, inspection, etc. He stated that stunting over cities and other flying, except at sufficient altitude, to enable reasonable certainty of safe landing in case of engine trouble, should be prohibited.

The paper on "Commercial Aviation in Europe," by Professor E. P. Warner, was an extensive review of the aeronautic situation in Europe. He contrasted the encouragement given aviation by the British, French, German and other European nations with the lack of such encouragement given by the United States Government. He stated that the airship has been proven more feasible for extremely long runs than the heavier-than-air type, but that the latter is very extensively and regularly used for mail and passenger carrying even over very long distances. As a rule, it is advisable to provide for regular landings at least once in each 250 miles. The fare from London to Paris is now about $36, or 15 cents per mile, and will probably be materially reduced in the near future.

Both England and France are laying extensive plans for using aircraft as a means for binding their respective empires together. England maintains an extensive ground organization, flying fields, issues weather reports and

warnings, and assists designers by extensive research work, engineering conferences, and competitions intended to develop new types.

The author predicted the development of large machines in which six to eight engines will be used, these being so arranged that individual engines can be stopped and repaired en route when this becomes necessary.

Ralph H. Upson presented a paper entitled "Transportation of the Immediate Future," in which he analyzed the economics of aircraft operation by means of charts which were explained in detail. This paper was followed by an informal talk by Major Lent of the U. S. Aircraft Mail Service. He stated that the cost of operation of the DH4 machines, being used by the Government, is approximately 70 cents a mile, and that this figure can be reduced to one-half by the use of machines especially designed for the purpose. The DH4 machine is equipped with a 400-hp. Liberty engine and carries only 400 lb. of mail, while it is possible to carry 1000 lb. in a machine equipped with a 200-hp. engine. Major Lent regards the multiple engined plane as necessary only as a means of avoiding an emergency landing. He prefers the use of a number of small planes in preference to one large machine for the reason that if the latter type fails in a given trip, the service is 100 per cent interrupted, whereas if four machines are used for the same service, it will seldom prove impossible for less than three to make a given trip. Hence the service will almost invariably be at least 75 per cent perfect. It is important to improve the reliability of aircraft, and to provide definite location finders in order that machines can fly above the clouds in case bad weather is encountered.

The session was concluded with a paper by S. W. Sparrow of the Bureau of Standards, the purpose of which was to show the effect of variations in compression pressures on engine performance.

Standardization and Co-operation Features of S. A. E. Body Session

By Norman G. Shidle

THE beginning of serious efforts at body standardization was the feature of chief importance which transpired at the body engineering session, while the need for better co-operation between chassis and body engineers was emphasized. The use of plywood, the training of competent workmen and the trend in body styles also came in for discussion.

Although the matter of body standardization was treated only briefly, an exceptional amount of interest attached to the discussion, and several very earnest pleas were voiced for action of some kind. One speaker, during the discussion, very emphatically declared the need for S. A. E. body standards to be vital since body men were now compelled to rely upon the standards set up by the manufacturers of the various products. He cited aluminum, cotton batting, and lumber as examples of materials for which standard specifications are necessary. He declared that trade names were used as a substitute for standards, so that it was, consequently, impossible to determine what sort of material was actually being bought.

The only paper which referred directly to this phase of body work was that of Kingston Forbes. Though discussing this subject very briefly, Mr. Forbes did make some concrete suggestions as to factors upon which work might be started. Some of the items suggested by Mr. Forbes which could be seriously considered for standardization are as follows:

1. Lumber specifications.
2. Cushion spring wire.
3. Fabricated cotton hair and burlap.
4. Imitation leather.
5. Top materials.
6. Webbings.
7. Closed body and windshield glass.
8. Automobile hardware.
9. Body bolts.
10. Curtain fasteners.
11. Bow sockets.
12. Top hardware.
13. Bow-bendings.
14. Back curtain lights.
15. Door handles.

Discussing the future of body standardization, David Beecroft, the new President, stated that a Body Standards Committee would probably be appointed and that he felt that definite action would be started along this line at once. He said, however, that he was unable to indicate exactly the direction which would be taken immediately by this work.

It would appear certain, however, from the discussion in regard to body standards, that there is a definite need for activity in this direction and that such activity is to be expected at once.

Co-operation with Chassis Engineers

Nearly every speaker, both those who read papers and those who entered the discussion, emphasized the need for closer co-operation between the body and chassis engineers. It was felt that very often the chassis engineer was allowed to complete his work according to his own ideas and that the body engineer was compelled to build a body to fit the conditions imposed by that chassis regardless of the possibility of doing so successfully.

The necessity for such co-operation was strongly urged by Charles A. Heergist in his paper on "Can Automobile Body Weight Be Reduced?" which was read by A. P. Cardwell. He brought up the question as to whether the chassis should be designed strongly enough to carry the entire weight or whether the body should be required to carry a large share. He stated that "if the metal frame sags, as the body is screwed to the metal frame, it carries the body with it at every downward movement; consequently the carrying capacity of the frame should be proportioned to the number and weight of the passengers, and the body built as light as is consistent with stability."

Such problems as these inevitably require close co-operation between chassis and body builders, since it is impossible for the latter to do his best work if he is forced to meet predetermined conditions.

George Kerr, body plant manager, Mitchell Motor Co., contributed some very valuable suggestions in discussing this phase of the subject. He cited an instance of a body concern which was building an almost exactly similar body for two different automobiles. Great trouble was being

experienced in connection with one of these machines, complaints coming in constantly that the bodies were shaking to pieces very rapidly and were giving very poor service.

Mr. Kerr believes that a four-point engine support reduces very greatly the wear and tear on a body as opposed to the three-point support, and in investigating the reasons for the difference in performance in these two cases, he immediately looked for this feature. He found that the car on which the bodies were giving such poor service had a three-point engine support and that the car on which they were giving good service had a four-point support. To this difference could be traced the variation in performance between the two makes.

The three-point engine support reduces vibration on the engine, but increases it on the body. Mr. Kerr pointed this out as an instance of what may be lost by lack of co-operation between body and chassis designers. When each one works according to his own ideas, the resulting job is not the best that might be turned out and the result is likely to be a "passing-the-buck" between body and chassis designers.

Uses of Plywood

Considerable discussion centered about the possibility of using plywood or laminated wood in bodies as a means of reducing weight. While various difficulties had been experienced by the different speakers, nearly every one agreed that there was some difficulty great enough to render it impracticable for production use.

Accurate Workmanship Difficult to Obtain

One of the chief difficulties in body work appears to be that of getting workmen to accurately carry out the ideas of the body designer. It was felt that the training of men capable of doing good body work was one of the big problems of the body designer or manufacturer.

Many times it has been impossible to get the drawing of the body engineer visualized in concrete form by the foremen and workmen who are responsible for the actual manufacture of the product.

Trend in Body Design

The trend in body design is toward a design that will please the majority of people, and because of quantity production needs inclines toward a reduction in the number of models offered by each manufacturer. This is the opinion expressed by George J. Mercer in his paper on "Style in Automobile Bodies."

"The number of different body models that will prevail during the coming season," Mr. Mercer said in part, "is less than in past years. For example, a few seasons ago one manufacturer listed 14 body styles that were in regular production. The greatest number of models listed by one manufacturer during the past year was eight; the majority listed four and this latter number probably will be the number of different models made by most manufacturers in the coming period or, if the touring car is considered, in two divisions, a total of five styles.

"The models that will prevail during the coming year are the five-passenger touring car, the two-passenger runabout, the five-passenger sedan and the four-passenger coupe. The seven-passenger touring car and the seven-passenger sedan will be made in limited numbers; at times the latter will be built with a division, thus making it a two-compartment car. The touring body, that has remained stationary for so long as regards development, is surely developing into two divisions to meet existing needs. . . .

"The four-door sedan as we have it today comes nearer to meeting with universal approval than any body design that has ever been introduced. It has superseded all other forms of closed body for general use except the coupe, which finds favor because it is a miniature of the four-door sedan. The sedan has been simplified in construction by using belt molding that runs all the way around, and the same condition exists at the drip. These two moldings eliminate the welding of the panel. The drip molding covers the top material edge effectively or at least permits the use of a small corner molding under which the top cloth is finished, without its being evident. . . .

"While there is a general tone of simplicity, the tendency is to make up in quality what is lacking in variety. It is reasonable to believe that this will be the prevailing spirit for the season to come. The automobile body is so well known, so generally used and so thoroughly understood by the public, that its intrinsic worth is becoming its best advertisement.

"Builders of the more expensive cars will always make their product of an approximately special-to-order class, Purchasers who are able to buy without counting the cost insist on body designs that are uncommon. Those who produce cars in large numbers for this class of trade usually follow a design that is not extreme, and that relies for its attractiveness upon the fine quality of the workmanship and the high quality of the material used. The chauffeur-driven car is the rule. The limousine and two-compartment sedan will prevail, with the town limousine, the town brougham and the cabriolet as the types having the lighter bodies."

Mr. Mercer also pointed out that there is a return to the type of body lines that preceded the prevailing style; that is, the straight line with angular corners is giving way to moderately rounded surfaces. At the same time, however, the straight line effect is being preserved to a large extent.

Production of All Metal Body

An interesting paper on "Passenger-Automobile Body-Designing Problems" was presented by Andrew F. Johnson.

George E. Goddard, of the Dodge company, presented an extremely interesting motion picture showing the methods used in manufacturing the Dodge all-metal body. He stated that it would take six months to make the dies necessary for this job and that a minimum production of 100 a day was necessary to render the process economical. The dies will last from four to five years.

In his paper on "The Body Engineer and His Relation to the Industry," Kingston Forbes divided the body engineer's task into two parts: artistic and mechanical. In the designing of custom-made bodies, he said, the artistic side is probably the most important, but he pointed out that in quantity production especially art had to be satisfied by dies and stamping machines.

The body engineer, according to Mr. Forbes, should be familiar with all the various trades which go to make up the finished body. While it is difficult for him to obtain this knowledge, he should obtain as much of it as possible. In this connection, the work of the body engineer might be divided into six divisions:

1. Body construction, open and closed.
2. Sheet metal, body metal, fenders, hood, radiators, etc.
3. Trimming.
4. Top building.
5. General hardware.
6. Painting and enameling.

This was the first session devoted entirely to body engineering ever held by the S. A. E. and over one hundred men attended. The discussion developed many interesting ideas, and an intense interest was manifested in the several questions mentioned previously. The meeting was in every way successful. It should pave the way to new achievement in the field of body engineering and help promote co-operation between chassis and body designers.

The Highway Session

By Clyde Jennings

THE first S. A. E. highway section meeting was instructive, interesting and, finally, entertaining. It was quite well attended, there being at one time fifty persons in the room and the total attendance reached a much higher figure. The attendance included a number of automotive engineers, several truck manufacturers and a considerable number of men who make highway work a chief factor in their every day affairs.

Col. H. W. Alden presided, and in his opening remarks called attention to a marked difference between the development in automotive and other means of communication. He said that in the case of the railroads, telephone and telegraph, the means of communication had been entirely within the custody of the persons who were responsible for the development of the theory. In automotive communication, men made the vehicles and then sent them out to run on a road that was outside of the control of the makers of the machine. The development of the means of communication had been everybody's business and, consequently, was not well attended to.

Responsibility of Automotive Engineer

The time had come, said Col. Alden, when the highways must be developed and the automotive engineer could not longer afford to neglect this problem. He called attention to the fact that the engineering schools had not developed a sufficient number of engineers to handle the great amount of work that is now called for.

Referring to the responsibility of the automotive engineers, he said:

"Merchandise transportation depends not only on cars and roadbeds, automobiles and highways, boats and waterways and, I might add for the future, airplanes and blue sky, but on the manner of use of these agencies. Here again we can learn a lesson from railroad experience. In the past the development of freight terminals and rail transportation has been under the same general guidance and the development of the two has been consistent and logical. The recent projection of the automobile into the transportation field has made possible wonderful changes in the methods of distribution of all commodities, but here again the automotive industry, as a whole, has neglected its full responsibility.

"It has failed to shoulder this responsibility for the correct use of the new instrument which it has produced, and for the proper correlation of it with previously existing instruments. I believe we are emerging gradually from our fools' paradise of money-making into a realization of this larger responsibility. How the railroads, highways and waterways can be best joined together in the general function of merchandise transportation is worthy of any man's time and intensive study. The correct solution and the proper arrangement of these three agencies will have a wonderful effect on the future of our industry.

"Freight cars average little better than 25 miles per day, due to terminal delays which could be eliminated largely if the motor trucks and railroads were in proper relation. This daily average could be lifted easily to 75 or 100 miles if the inefficiency of present terminal methods were eliminated. This is no idle dream. The basic trouble is that railroads are doing an enormous amount of less-than-carload, short-haul work for which they are not so well equipped as is the motor truck. The average distance that each ton of freight is hauled by rail is less than 200 miles, due to this large amount of short-haul tonnage.

"A proper re-arrangement wherein the motor truck would do the short-haul and the less-than-carload work and the railroads the long-haul work would give us a regular freight transportation more speedy than to-day's average express shipments and at a cost far less than anything dreamed of to-day. However, I have seen little indication of study of this problem by the automotive industry as a whole, or of co-operation with the railroads in its solution, until very recently. We cannot pass the blame on to the railroads.

"The responsibility is our own. It is a challenge to the brains of the automotive industry and, unless we get busy and assist in the solution of this problem, the progress of the truck industry will be slow where it might be rapid. The details of these questions are numerous, but they are not difficult of solution. They must, however, be honestly faced and understood. Then, if honestly attacked, the results will revolutionize our transportation business.

"I am fairly well acquainted with what our industry has done in the fields of highway development and merchandise transportation, but I repeat that what has been done is only a drop in the bucket. I am greatly pleased that our Society is showing signs of life in these two directions, as they are at the very foundation of our future success and expansion. It behooves every automotive engineer to devote a goodly share of his time to studying these two questions. I hope what I have said will direct our attention more and more to these fundamental problems, the solution of which is as much our responsibility as it is that of the railroad and highway engineers."

Bureau of Roads Tests

A. T. Goldbeck, engineer of tests of the U. S. Bureau of Roads, showed many lantern slides concerning the research and experimental work of the Bureau. In showing these slides, which were photographs of the equipment for the experiments, the operations and of curves of deduction, he asked that those present do not accept the figures given as final as to detail. He said that the Bureau was checking the data gathered and shortly would issue a bulletin in which much of this data would be compiled. In the meantime he asked that his talk be construed as merely a progress report. His talk was especially interesting as to determining the weight distribution on the wheels of the vehicles by means of the device which is buried in the soil under the surface of the road. Thin brass sheets are arranged to measure the slightest change of pressure in the subsoil through the breaking of the electrical circuit. This device has suppplied new data as to the extent of the pressure under the wheel of the truck. The change in pressure, of course, varies with the nature of the subsoil.

He also showed the experimental bits of roads built with a view to determining to what extent moisture can be kept from the subsoil by waterproofing the shoulders of narrow surface roads. He showed the machinery and operations for determining the impact of trucks on a given set-off in the road surface. One rather peculiar feature developed in this experiment was that while there was a wide range of difference in impact in favor of a new solid tire as against the seriously worn solid tire, and again in favor of the pneumatic tire as against any solid tire, there was a comparatively slight range between the pneumatic with 160 lb. pressure and the pneumatic at 130 lb. This difference was much less marked than was expected.

This statement was subject to some discussion and Goldbeck explained that while the under-pressure pneumatic was regarded as a more comfortable tire for riding on a rough road, this was due to the time element entering into the impact.

Goldbeck, in summing up, said that with increasing loads he had become interested in the problem of distributing the load on more wheels. The parallel for this, he said, was in the railroad work. As the size and weight of locomotives increased, the number of wheels had been increased. He also said that the question as to the relative cost of the highways and the cost of the motor trucks that passed over it had been raised, and in his opinion the question of designing either the highway or the motor truck might ultimately be determined by economic considerations.

Later in the discussion, David Ludlum of the Autocar Co. asked Goldbeck how many types of trucks had been used in these experiments and how many would be used before the question as to the design of a truck was passed upon. Goldbeck in reply said that seven or eight designs had been employed, but that these experiments were for the purpose of determining highway research material and not with a view of deciding upon any truck design. In answer to another question by Ludlum, he said he would be quite glad for the opportunity of using a short wheelbase truck in the experiments. He passed the question as to the use of data gathered in these experiments in advertising certain trucks, by saying that so far only progress reports had been issued and that he would much prefer that no such reports be made. His idea was that the data should not be made public until completed, but that in government work it appeared to be necessary to issue reports from time to time, and that these reports were often mistaken for complete reports and so used. He could not stop this practice.

William E. Williams, a consulting engineer, read a paper on "Highway Road Construction," on experiences drafted chiefly from civil and railroad engineering. Williams expressed slight patience with much of the research work on highway problems, strongly favoring a brick and concerete road of sufficient thickness—10 in. appeared to be sufficient to him—to support the traffic. He said that if such a highway was made, there need not be much worry about the subsoil pressures and drainage. The paper was the subject of quite a number of comments in the discussion, in which many statements were disputed. Most of those present appeared to think that Williams had ignored the necessary question of cost.

H. E. Breed of the New York State Highway Department, in his paper on "Variable Factors That Influence Highway Design," made the political side of road building the prominent one. He favored a department that was not a part of the political booty. Political domination, he said, was one of the chief evils of the day.

Another variable factor of importance is the volume and character of the traffic of to-morrow. He said that he did not believe any engineer to-day faced this problem with confidence. He passed quickly over the other variables, which he said were foundation, surfacing, drainage and maintenance.

A. E. Masury showed two lantern slides of a device that he had built for measuring the effect of road jolts on the truck. The measurements are made on a paper cylinder by a pencil controlled by an air cylinder. The seismograph chart is timed and relative data can be obtained over the same roadway. This entire work, he said, was in a very experimental stage.

One of the highly interesting contributions to the discussion was that of State Highway Engineer Meeker of New Jersey. His view was that the greatest single factor in the highway problem was that of maintenance. The present tendency was to build a highway—good, bad or indifferent—and then forget it until it was necessary to build it over. It would be well, he said, to follow the railroad practice, where regularly section gangs were responsible for certain mileage of track. Highways needed repair men constantly on the job, they needed track walkers, they needed renovations and general repairs in the fall and spring; the first to prepare for winter and the second to repair the damage of winter. With this sort of treatment, Meeker said, many types of highways now condemned would stand the heavy traffic wear. Others who participated in the discussion were David Fenner, Cornelius Meyers, S. M. Williams, H. W. Slauson.

In adjourning the session Chairman Alden said that he understood that it was the plan to hold future sessions of this nature, and while this had been strictly a highway session, he thought that future meetings would be based on a consideration of the general subject of transportation.

The Standards Committee Meeting

By P. M. Heldt

THE Standards Committee met on Tuesday morning at the Engineering Societies Building, Chairman B. B. Bachman presiding. The first report presented was that of the Aeronautic Division, by H. M. Crane. It proposed a revision of the tables of turnbuckle dimensions, to bring the S. A. E. specifications in line with the specifications of the Bureau of Aircraft Production. In the discussion, an exception was taken to the wording of one recommendation, that the barrels should be made "of naval brass or an equivalent alloy." This brass is equivalent to S. A. E. non-ferrous alloy No. 73 and it was held to be more fitting to use the latter term. The suggestion to substitute this term was put in the form of an amendment, which was carried, and the part of the report dealing with turnbuckles itself was then adopted. J. L. Hartness said that the turnbuckles covered by the table were good for cables up to ¼ in. diameter, and since we were now getting into larger sizes of aircraft, it would be well to extend the table to include turnbuckles suitable for 5/16 in. cable at least. The suggestion was brought to the attention of the Aeronautic Division.

Federal Aircraft Registrations

The second part of the Aeronautic Division report was in the form of a special report on the regulation of commercial air navigation. Mr. Crane said that there was every evidence that legislation would soon be adopted by various states seriously restricting the use of aircraft, and that it was highly important for the S. A. E., which was an organization endeavoring to encourage experimental development of aircraft, to see to it that no undue restrictions be placed on machines which had not yet proven absolutely safe, provided that the men who did the flying were cognizant of the risks they were taking. Mr. Crane said that this was not entirely in line with the usual work carried on by the Standards Committee, but that it was necessary to take action on the report for the guidance of the Sub-Division on Performance and Testing. The special

report read as follows:

"A system of Federal registration of all aircraft for identification, and in addition, licenses for certain specific purposes or uses should be adopted.

"All aircraft carrying passengers for any purpose, or goods in commercial service, should be licensed by the Federal authority, which license shall indicate the aircraft licensed has complied with certain minimum requirements as to safety. By passengers is meant any person not a necessary member of the crew.

"Any aircraft not coming under the classification in the previous paragraph may be licensed by the Federal authority even though not complying with the safety requirements, but only for restricted service with a view to minimizing danger to persons or property on the ground. This is intended to cover experiment and special racing aircraft as well as privately owned aircraft not used in commercial or Government service.

"Minimum requirements cannot, even as regards the structural strength, be reduced to rules and figures capable of application in inspection except by persons of adequate engineering training in this field, and other necessary minimum requirements regarding safety of operation are the result of compromise and can only be applied by persons with trained judgment.

"Any definite requirements or figures should not be written into legislation at this time, because these matters would be handled best by the regulation and ruling of the Federal authority which should be created by legislation.

"Aircraft, which, in accordance with previous paragraphs, require a license, should be periodically inspected to insure that they continue to be in a safe operating condition."

Ball and Roller Bearings

W. R. Strickland made the report of the Ball and Roller Bearings Division. The first item covered a proposed extension of the standard for angular contact ball bearings. It was recommended that the bore, outside diameter and eccentricity tolerances specified for light, medium and heavy series annular ball bearings, be adhered to for the angular contact type, and that the tolerances for the overall widths be specified with the footnote reading: "The width tolerances for the individual ring shall be the same as those for the corresponding sizes of annular ball bearings of the light, medium and heavy series." It was also recommended that the angular contact type bearing tables be published as separate and complete standards. The recommendation was adopted.

Under the heading of the separable (open) type, it was recommended to revise the present standard by changing the heading in the column "Width of individual ring" to "overall width," and to add tolerances of plus or minus 0.002 in. to the overall width dimension. A footnote is to be added, referring to overall width, to the effect that "The nominal width of individual rings shall be the same as for the overall width in the above table, but shall have tolerances of plus or minus 0.001 in. This was adopted.

It was further proposed to change the designation "extra wide type" to "wide type," to add a note to the effect that "The bore and outside diameters for wide type annular ball bearings shall be the same as for the corresponding size annular ball bearings in the light, medium and heavy series," and to add a footnote referring to the title, to read: "Normally these bearings are a double row type of construction." This was adopted.

Shaft and Housing Fits

Under the heading, "Shaft and Housing Fits and Tolerances for Ball Bearings," there were presented two tables which it was proposed to print in the S. A. E. Handbook for general information only. These tables gave the nominal dimension, plus and minus tolerances of the inside diameter of the bearing, the shaft diameter, the outside diameter of the bearing and the housing bore. H. M. Crane thought that the information contained in the tables should be presented in a slightly different form. On steering knuckles, for instance, it would be commercially impossible to work to limits of 0.0005 in. He suggested that instead of giving the nominal diameter with plus and minus tolerances, on both the hole and shaft, only the extreme permissible differences between the shaft and hole sizes be specified. For instance, for the 30 mm. bore size of ball bearing, these figures would be 0.0002 in. looseness and 0.0009 in. tightness. It might be practical to work to a limit of 0.0005 in. in the manufacture of ball bearings, but it was not commercially practicable to work to such close limits in machining the bores of wheel hubs, for instance. Mr. Strickland explained that the figures in the tables were based on grinding fits, and he thought they were not as impossible as Mr. Crane suggested. These limits had been worked to by many manufacturers. In the larger sizes the tolerances were not of the order of 0.0005 in. but approached 0.002 in. Mr. Cookingham said he could not see how they were going to check such close dimensions, as a micrometer was absolutely unsuitable for checking dimensions given to the 10/10000 part of an inch, and very fine instruments would certainly be required. Mr. Scaife voiced the opinion that a looseness of 0.0002 in. would never do, because even with a ground surface, the bearings would soon begin to shake and give trouble, and with a machined surface it would be still worse. Mr. Gurney said that the limits which had been put into the tables were almost impossible, and that the only way to get the desired fit in most instances was by selection. Where this was impossible, the figures given might be used as a guide. Mr. Crane said he had had a great deal of experience in studying tolerances in connection with the manufacture of aircraft engines for the Government during the war, and that they had finally agreed on the system which he now proposed, which system was greatly appreciated by the shop men. Mr. Crane's amendment to present the dimensions in a somewhat different form was carried, and the report thus amended was adopted.

Electric Vehicle Battery Jars

The next report presented was that of the Electric Transportation Division, which related to electric vehicle storage battery parts, for passenger and commercial vehicles. The report was presented by E. L. Clark, and was merely a revision of an earlier standard. W. E. Holland suggested that in the two-ribbed type of jar, where the centers of the ribs were shown 3½ in. apart, this dimension be left off, as some of the jar manufacturers were making the ribs 3¼ in. apart and it would be a very expensive matter for them to make this change, for which there was no particular reason. An amendment to this effect was carried, and then the whole report was adopted.

Lighting and Starting Batteries

Next the report of the Electrical Equipment Division was taken up, being presented by A. D. T. Libby. This division appointed a sub-division on storage batteries during the year 1919, to cooperate with the Bureau of Standards and the Motor Transport Corps in the formulation of specifications for starting and lighting storage batteries for military automobile and motor truck service, for the use of the Government, and to revise the present storage battery standards. Under the heading of "Rating" it was recommended that "Batteries for combined starting and lighting service shall have two ratings. The first rating shall indicate the lighting ability, and shall be the capacity

in ampere-hours when the battery is discharged continuously at the 5 hr. rate to a final voltage of not less than 1.7 per cell, the temperature of the battery beginning such discharge being 80 deg. Fahr. The second rating shall indicate the starting ability and shall be the capacity in ampere-hours when the battery is discharged continuously at the 20 min. rate to a final voltage of not less than 1.5 per cell, the temperature of the battery beginning the discharge being 80 deg. Fahr."

Under the heading of Terminal Posts, it was recommended that when taper posts are used for terminals of lead-acid storage batteries, the dimensions shall be 5/8 in. for the small diameter on the negative post, 11/16 in. for the small diameter of the positive post, 1⅓ in. taper per foot, and 11/16 in. minimum length of taper. When straight terminal posts are used, the diameter of both the positive and negative posts shall be 13/16 in. and the minimum clear length of the post shall be 13/16 in. On the subject of terminal posts, there was a communication from Robert H. Combs, in which objection was raised to the decision to make the positive and negative posts of different diameters if they be tapered, but of the same diameter if they be straight. The explanation given was that straight terminal posts had never been made of different diameters, and since it was the object of the Standards Committee to simplify construction and reduce the number of different parts, it was not considered opportune to recommend straight posts of different diameters.

The principal changes from present practice recommended in the report may be summarized as follows: The report was specifically limited to lead-acid storage batteries, in order that the specifications would not be applied to Edison storage batteries. The S. A. E. Recommended Practice for posts for small cells was omitted, as the battery sizes proposed for adoption did not require the use of small terminal posts. The compartment height of 10 in. specified in the former S. A. E. standard for storage battery compartments was changed to 10⅛ in. The former S. A. E. standard for dimensions of lead-storage batteries for starting and lighting service was revised to specify a list of the sizes and capacities based on present practice, which was considered comprehensive enough for practically all commercial requirements. The former S. A. E. standard for ratings of lead-storage batteries for starting and lighting service was revised to conform to acceptable commercial practice.

The specification regarding fuel capacity was changed, the following passage being deleted: "With a current 25 per cent greater than the rating, the fuse shall open the circuit without reaching a temperature which will injure the fuse tube or terminals of the fuse block." It was recommended that the fuse clip and fuse ferrule should be nickel plated and that the fuses should be tested in both the vertical and horizontal positions. This section of the report was adopted.

Spark Plug Tests

Another section of the report dealt with spark plug tests. Last year the Division co-operated with the Motor Transport Corps in the establishment of a Government specification for the testing of spark plugs, and from this work were developed recommendations for commercial use. The recommendations were prepared by a sub-division, and tried out by making tests. The following was accepted as recommended practice in making spark plug tests:

"A sufficient number of sample spark plugs drawn at random from stock are to be furnished to equip at least two of the engines under consideration.

"The spark plugs submitted for test must conform in all important dimensions to the engine builder's drawings.

"Preignition and leakage tests are to be made in the following manner. An engine of the type for which the plugs are intended shall be equipped with a set of the spark plugs to be tested. The spark plug gaps shall be carefully adjusted with a suitable thickness gage to the desired dimension and these gaps shall not be disturbed throughout the tests. The engine shall then be coupled to a suitable dynamometer and the circulating water maintained at a temperature of not less than 40 deg. Fahr. or more than 60 deg. Fahr. The engine shall then be started up and as rapidly as possible brought to the speed corresponding to the maximum torque, the throttle and the spark adjusted for this condition, and the circulating water temperature brought up to a temperature of not less than 190 deg. Fahr. nor more than 210 deg. Fahr. as rapidly as possible and this temperature maintained for the remainder of the run. Torque and speed readings shall then be taken at 30-sec. intervals for a period of 15 min. Appreciable loss of torque or speed, missing or backfiring which can be attributed to the spark plugs, will be considered grounds for rejecting the spark plugs under test, provided the engine is of proved design and has previously demonstrated its ability to run steadily under these conditions. During this run, tests for gas leakage shall be made by covering all joints of the spark plugs with oil and inspecting for leaks.

"Following this 15-min. run at the speed corresponding to maximum torque, the engine shall be brought up to the speed corresponding to maximum horsepower and be held at this speed for not less than 5 min. Obserations similar to the previous will be made during this run.

"Spark plugs shall also be subjected to road tests to determine how well they will function under normal service conditions.

"Spark plugs which have successfully passed the above tests will be considered satisfactory for use in so far as the following points are concerned:

"(1) Breakage owing to sudden temperature changes.
"(2) Liability to cause preignition.
"(3) Leakage.
"(4) Power performance.
"(5) Permanance of gap.

"The following procedure for determining the relative susceptibility of the spark plugs under text to fouling is intended to servev merely as a guide in making such tests, since general engine influences and more particularly lubrication and carburetion conditions varying as they do in different makes of engine, prohibit the setting of one strictly standard method applicable to all engines.

"The engine equipped with the spark plugs under test shall be run on the dynamometer with the circulating water at not less than 40 deg. Fahr. nor more than 60 deg. Fahr. The inlet manifold shall be kept at as low a temperature as practicable, all heating means being disconnected so far as possible. The engine shall be run with no load and a wide open throttle, the speed being held down to between 1000 and 1500 r.p.m. by causing the carbureter to feed an abnormally rich mixture. The engine shall be run in this manner for 3 min., following which the carbureter adjustment shall be restored to standard condition and the load applied to hold the engine at a speed of about 1200 r.p.m. It is assumed that the torque which is to be expected of the engine under test at this speed, has been previously determined. At the end of 2 min. running after applying the load as above explained, the percentage of standard torque which the engine is capable of developing will be considered as a figure of merit for the spark plugs under test. For instance, if at the end of 2 min. operation under load following the "choked" run, the engine is capable of pulling its standard torque, the spark plugs shall be considered 100 per cent satisfactory in this regard. If, however, the engine pulls but one-half its regular torque, the figure of merit will be 50. These tests should be re-

peated a sufficient number of times to insure a consistent average result."

Magneto Standards

Under the heading of Magneto Dimensions it was recommended that the present standard be extended to include small magnetos used on motorcycles and isolated electric lighting plants, these magnetos to have the same size taper as given in the present Recommended Practice for larger type motorcycle magnetos. This was adopted.

It was also recommended that on flexible disk magneto couplings "cups or a similar form of grip washers shall be used on the flange bolts on each side of the disk, to reinforce the material against tearing out." This recommendation was objected to by Fred W. Andrew, on the ground that the S. A. E., by standardizing features of flexible disk couplings for magnetos, and not standardizing other types of couplings, gave the impression that the flexible disk was the only type recommended for magneto use. The very fact that grip washers were recommended in the report showed that this coupling as now used gave trouble, and since there were other types of couplings, it was suggested that the matter be referred back to the committee and that the present standard for flexible disk couplings for magnetos (covering diameter of disks and spacing of bolts) be eliminated from the records of the Society. It was voted to refer the matter back to the committee.

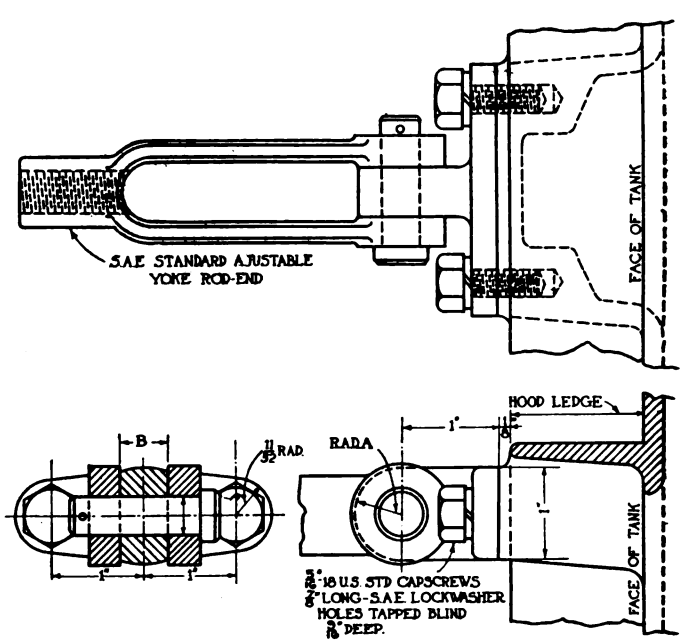
Starter Pinions and Brushes

In connection with starting motor pinions it was recommended that the pitch-line clearance between pinion and flywheel, which is now specified as 0.015 in., should be specified as 0.015 to 0.025 in. After some discussion it was decided to substitute the phrase, "Clearance on the pitch-line," for pitch-line clearance, and thus amended the recommendation was accepted.

The Division had been requested to standardize commutator brushes for generators and starting motors, but found that the only thing that could be done at the present was to recommend the following: "All dimensions for brushes used in starting motors and lighting generators shall vary by even increments of 1/16 in. and the maximum tolerances from nominal size shall be plus 0.000 minus 0.010 in. for width and thickness and plus 0.000 minus 0.031 (1/32 in.) for length." This was adopted.

It was also recommended to delete from the records of the Society the following standard which had never come into practical use: "Before any electrical appliance is added to a gasoline car, as it is sent out from the car manufacturer's plant, a description of the said appliance should be submitted to the car manufacturer as to suitability for and the best method of application to the car." This was agreed to by the committee.

K. F. Walker presented the report of the Radiator Division. It was recommended that in cast radiators "inlet and



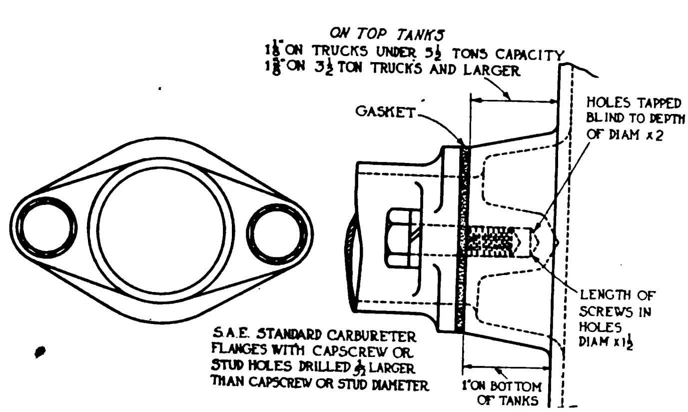
Cast radiator tie rod fittings

outlet fittings shall be cast separate from the radiator tank" and that they "shall be attached to the tank by flanges which conform to the present S. A. E. Standard two bolt type carbureter flanges of the 1, 1¼, 1½, 1¾ and 2 in. sizes. The finished face of the pad cast on the radiator tank shall extend ⅛ in. outside of any other projection on the tank. The drilled holes in the fittings shall be 1/32 in. larger in diameter than the cap screw or stud diameter. The tapped holes in the pad on the tank shall be blind with a maximum tapped depth of twice the cap screw or stud diameter. The length of the cap screws or studs in the tapped hole shall be 1½ times the diameter.

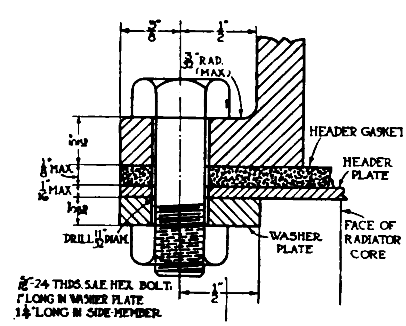
"In the tubular radiators, having internal overflow tubes, the tubes shall be of seamless brass or copper, attached to the bottom tank by a ½ in. American standard pipe thread brass plug. The jacket tube shall be ⅝ in. diameter and the overflow tube shall be ⅜ in. diameter.

"The size of the tapped hole for radiator drains shall be ⅜ in. American standard pipe thread. Bolt hole centers of header flanges shall be spaced 2½ in. apart wherever possible. Cast radiator tanks shall be designed without ribs or cooling flanges. Tie rod fittings shall be in accordance with the illustration.

"A pressure of 5 lb. per sq. in. shall be used in making all tests for radiator leaks. Header plate widths shall be 5, 5½, 6, 6½ and 7 in. The hood ledges of cast radiators shall be 1 in. wide on motor trucks having a nominal capacity of less than 3½ tons, and 1½ in. wide on motor trucks having a nominal capacity of 3½ tons or more."



Inlet and outlet flanges



Cast radiator header flange dimensions

In connection with passenger car radiators, the following recommendations were made: "The tie rods connecting the body (dashboard) and the top of the radiator shall be flexible. The hood ledge shall have a minimum width of 7/8 in. Hood lacing shall be not less than 3/8 in. wide, and not less than 1/8 in. thick." The whole report was adopted as presented.

S. P. Thatcher presented the report of the Tire and Rim Division. This contained only a single suggestion, namely, the extension of the present wood felloe dimensions standard for pneumatic tire rims, to include the 34 x 5 in. wood felloe having a width of 2½ in. and a depth of 1⅝ in., plus or minus 1/16 in. This was adopted.

New Non-Ferrous Alloy Specifications

J. J. Aull read the report of the Non-Ferrous Metals Division, which had revised all of its previous standards. This report included four specifications of white bearing metals or babbitts, Specifications Nos. 10, 11, 12 and 13. These were adopted as presented. Then there were four specifications of aluminum alloy, of which the first three were old and the last new. These specifications, Nos. 30, 31, 32 and 33, were accepted as presented. Next came eleven specifications of brasses and bronzes. One speaker said he regarded the requirement of 8 per cent elongation in specification No. 64 (phosphor bronze) as very high, as it was the practice of his firm to call for 4 per cent only. He was reassured, however, that the elongations requirements for specifications 64 and 65 were well within the limits of practical possibility. This set of specifications was adopted. Next No. 69 was taken up, which covers a new wrought aluminum bronze. This also was accepted. Specification No. 70, covering commercial brass sheets, embodies only a slight change, made to bring it into line with the A. S. T. M. Specifications. This was adopted. No. 71, covering copper sheet, was also adopted. Specifications Nos. 72, 73, 74 and 75 covered brass rod and tubing, and were adopted.

Tractor Belts and Governors

E. A. Johnston presented the report of the Tractor Division. In this it was recommended that belt pulleys and clutch diameters for new equipment should not be less than 12 in. and the pulley width should not be less than ½ in. wider than the belt required. Tractor drive belts for all purposes should be 5, 6, 7, 8 or 9 in. in width. This was adopted.

It was also recommended that farm tractors and engines intended for belt operation be equipped with a governor and so designed that a suitable speed indicated device might be attached. This was also adopted. On a previous occasion, the Society adopted a standard testing form for tractor engines. Mr. Johnston said that this had never come into practical use, and the Division wanted it eliminated from the standards of the Society. This was agreed to.

Screw Thread Standards

W. R. Strickland read the report of the Miscellaneous Division. This covered two items, namely, the proposal to adopt as an S. A. E. standard the American standard taper pipe thread, and a revision of the present S. A. E. oil and grease cup thread standards. At present taper threads are used in only a few of the S. A. E. Standards, namely, flared tube unions, ells and tees, fuel vacuum tanks, pipe flanges and oil and grease cups. In 1919, a committee of the A. S. M. E. held a public hearing for the consideration of international pipe threads, and following this hearing, the S. A. E. was requested to give official endorsement to the American standard taper pipe thread and to authorize an American representative in Europe to use the endorsement in propagating the standard among European manufacturers and technical organizations, prior to a contemplated international conference. It was decided to adopt the American standard taper pipe thread as an S. A. E. Standard.

In August, 1920, the Society adopted ¼-36 and 5/16-32 threads for oil and grease cups. There has been much criticism of this standard, for the reason that the common standard fine thread pitch for ¼ in. diameter is 32. The Miscellaneous Division at this meeting, therefore, recommended the addition of a No. 10-32 size and to change the ¼-36 to ¼-32 thread. This recommendation was accepted.

Engine Division Report

In the absence of any members of the Engine Division, the report of that Division was read by Manager Burnett of the Standards Committee. In this report it was recommended that "mufflers shall vary in diameter and length by even inches, and shall be supported by bands extending around the circumference." In connection with flywheel housings, it was recommended that the following recommended practice be added to the present standard: "The clearance space for crankshaft flange bolts shall be 6⅛ in. maximum diameter, and at least ⅝ in. deep." At the suggestion of the Truck Division, it was recommended to add two sizes to the present fan belt and pulley width standards, namely, belts 1¾ and 2 in. wide, and pulleys 2 and 2¼ in. wide, the limits on the belt widths being plus and minus 1/32 in. and the limits on the pulley widths plus and minus 0.005 in.

It was also proposed to standardize the air inlet openings of tractor carbureters so as to facilitiate the fitting of air cleaners. The recommended practice is as follows: "The nominal diameter of the carbureter intake shall be the inside diameter, which shall vary in even quarter inches (from ¾ to 4 in. diameter) so as to take standard tubing sizes as listed in the present S. A. E. Standard for Flexible Metal Tubing, page 35b, S. A. E. Handbook, Vol. 1. This also applies to the outlet of carbureter air cleaners, and similar devices wherever tubing is used." It was also recommended to cancel the present S. A. E. Recommended Practice for carbureter air heaters, as this practice had become obsolete. All of the recommendations of the Division were accepted.

Motorcycle Standards

Mr. Burnett also read the report of the Motorcycle Division. This included a recommendation for a slight change in the chemical composition of the steel for motorcycle spokes and nipples so as to make this specification identical with S. A. E. specification No. 1045. It also recommended a slight change in the specification of the steel used for motorcycle wheels and rims so as to make the latter identical with S. A. E. specification No. 1010. A further recommendation was to cancel the recommended practices for spark and throttle controls, clutch and brake pedals and gearshifts, which were formulated as military standards. All of these recommendations were accepted.

Truck Standards

A proposed standard emergency rim clamp so designed that a truck equipped with 36 x 6-in. wheels in front and 40 x 8-in. wheels in the rear can carry a 38 x 7-in. rim as spare with a 40 x 8-in. tire (the latter being a standard oversize for 38 x 7-in.) and thus make it unnecessary to carry two sizes of spare tires was submitted, but was referred back to the committee because the discussion made it evident that the proposed lug had not been sufficiently well tested to make certain that it would prove satisfactory in actual service. A slight revision of the present standard rim clamp bolts was approved, as was also a set of standard dimensions for passenger car wheel spokes.

Completion of Front Hub Standards Postponed

By J. Edward Schipper

HUB standardization has received a six months' setback chiefly because the report covering the proposed standard specifications was not presented in a form acceptable to the S. A. E. Standards Committee. While members of the committee were almost unanimous in their approval of the spirit of the report, it was felt that the printed report brought before the standards meeting did not satisfactorily present the work of the committee and that it would consequently be advisable to refer the matter back. Action to this effect was taken with the result that the report will not come up for final actions until the summer meeting of the Society is held.

The discussion of the report brought out the fact that all the manufacturers vitally concerned approve of the work. Objections were made by the Gurney Ball Bearing Co. that the report did not cover the installation of ball bearings, and in view of these objections the title of the report, when it next appears, will be Roller Bearing Front Hubs for Trucks instead of Hubs for Wood and Metal Wheels.

In discussing the objections of the ball bearing manufacturer to these recommendations, it was pointed out that 95 per cent of the installations are roller bearing, the notable exception being that in the White trucks. This company manufactures its own axle and consequently does not materially affect the situation from a standards standpoint. It was also pointed out in answer to many questions on this point that it is impracticable to have a common standard for both the ball and roller bearings because, where the same diameters can be used, the capacity rating of the ball bearings will be about 70 per cent of the roller bearing capacity.

Campaign Begun Last June

Largely through the efforts of AUTOMOTIVE INDUSTRIES, which has frequently noted with concern the annual waste and inconvenience to the trade of unstandardized hubs, the program for motor vehicle hub standardization was inaugurated in June, 1920, by representatives of wood and metal wheel manufacturers in cooperation with manufacturers of axles, hubs, bearings, rims and tires. This program has been carried out by a committee consisting of four representatives of prominent manufacturers of axles, C. T. Myers, chairman, and the Standards Manager of the S. A. E., ex-officio, secretary.

The standardization of wheel hubs for front and rear axles for both passenger cars and motor trucks was too big a task to be undertaken at one time, hence it was agreed that consideration of rear axle hubs should be deferred and that only front axle hubs for motor trucks, which afforded better opportunity for immediate progress should be considered in the first instance. Following completion of this part of the program, work will proceed on passenger car front axle hubs and then on rear axle hubs for both types of vehicle.

It is evident that since real hub standardization depends upon bearing sizes and location, which in turn depends upon spindle design, the logical procedure was to design a series of spindles for load capacities that would cover the range of the various motor truck models having load capacities from ¾ to 5 tons.

In order to have a minimum number of spindles, the passenger car and motor truck requirements were studied and ratings selected that permit the use of the lighter truck axles on heavy passenger cars, or vice versa. From this followed the selection of proper bearings for these spindles and the design of wheel hubs to fit these bearings.

The proposed designs for the five sizes of spindles and hubs for motor trucks have been laid down on the basis of definite maximum load ratings in pounds on the tires at the ground, so that they can be checked up to determine whether or not any particular spindle is being overloaded, by simply running the front wheels of a motor truck onto a platform scale. These ratings were selected with reference to existing practice in motor truck construction, and to the load rating of the solid tire and wheel built around each spindle and hub.

The spindles and hubs have no other rating, however, than that of their capacity in pounds on the tires at the ground. No matter what the rated load capacity of the motor truck may be, the spindle and hub to be used will depend upon the weight distribution of the loaded vehicle, which determines the load the front wheels must carry. This weight need not be as of estimate only, as it can be checked by the scales measurement.

The spindles are so designed that the center of the tire where it touches the ground is vertically under the center of the inner bearing. This arrangement differs from that in many designs of truck front hubs now in use in that it brings the point of contact of the tire on the ground considerably nearer the projection of the steering pivot center on the ground and makes steering much easier. For a given tread and frame width it permits a greater angular movement of the front wheel and therefore a shorter turning radius. It also reduces to a marked extent the pressure on the steering pivot and its bushings. The location of the tire so that the load is under the inner bearing instead of between the bearings, also reduces the bending moment, which is due to the vertically applied load on the spindles. In the case of many axles now in use, this bending moment is three or four times as great as in the case of the proposed standard spindles.

Spindle Design

The spindles have been designed with large fillets at the shoulder, an important feature that has often been slighted in the past. It strengthens the spindle at the point of maximum stress and has the effect of moving the shoulder toward the load line, thereby decreasing the moments by shortening the lever arm to the point of load application. General practice among axle makers is to use a low nickel or chrome nickel steel, such as S. A. E. No. 2340 or 3140, for spindles, but the stresses in the proposed spindles will be low enough to allow the use of S. A. E. Steel No. 1035 if it should become necessary to do so under extraordinary circumstances.

It may be questioned why smaller spindles are not proposed in order to lighten and cheapen the axles and work

the steel closer to its elastic limit. This is not done because absolutely safe practice must be observed for standard use; bearings large enough to serve in these hubs permit the use of the spindle sizes recommended; the proposed spindles actually weigh less than many spindles in present use for the same service; and in event of a shortage of alloy steel a carbon steel can be used.

The selection of the bearings was guided by a study of the types, sizes and extent of their use for this application in the trade at this time. Figures for 1919 show that about one and a quarter million bearings were used on commercial car and motor truck front axles. Taper roller bearings constituted about 90 per cent of the total, straight roller bearings constituted less than 5 per cent, and ball bearings about 5 per cent of the total. The main advantages of roller bearings over ball bearings on front axle spindles are greater durability, ability to withstand heavy end thrust loads, permissible use of smaller sizes and their lower cost.

This work was started with the intention of establishing, if possible, hub and spindle dimensions whereby ball and roller bearings would interchange, but it was found that there would be difficulty in getting recommendations from the manufacturers of ball bearings and roller bearings by which such interchangeable dimensions could be developed. After careful consideration, it was not deemed reasonable to burden the entire industry with the extra expense and weight which such a set of hubs would entail in order to afford interchangeability for a type of bearings that constitutes but one-twentieth of the production for motor truck front axle hubs. Further, this one-twentieth part is practically accounted for by the bearings used in the motor trucks of a single large producer, which to some extent makes its own bearings. Long experience in the use of these bearings has made it evident that they are so large that they could not be worked into the proposed standardization with any reasonable expectation of adoption.

Eliminating the bearings used by the one company referred to it was found that roller bearings covered by the spindle sizes proposed have been used by practically the entire motor truck industry. To do otherwise than adopt these sizes would offer grounds for grave criticisms, and would undoubtedly open the way for rejection of the program by those most interested in it.

There are at least four manufacturers of taper and straight roller bearings which can furnish interchangeable bearings for the proposed hubs. Even had the hubs been made large enough to take the bearings recommended by the ball bearing manufacturers, they would have varied enough from the roller bearing dimensions to have necessitated complete additional tool equipment, and real interchangeability would not have been possible.

The advantages of hub standardization have been dealt with in several articles in AUTOMOTIVE INDUSTRIES, and there is no fear among those who have been working with this project that this minor setback will discourage the members of the committee. Such minor differences as have existed are already wiped out, or are well on the road to being eliminated. The revised report will doubtless be adopted at the summer meeting.

The Business Session

By Herbert Chase

PRESIDENT VINCENT opened the business session with an address in which he reviewed the work of the past year and indicated in what direction he felt this work could profitably be extended. He stated that the Society is taking part in the work of the American Engineering Standards Committee while still reserving its right to independent action, but has declined the invitation to join the American Federation of Engineering Societies largely because it is felt that the funds the S. A. E. would be called upon to expend in this direction are considerable and can be used to better advantage in other activities. He favored continued co-operation with the American Petroleum Institute and said that he believes the standards work of the Society should have more publicity during the formative stage in order that all who have a legitimate interest will be able to follow its progress and offer constructive criticism. He stated that the Council of the Society has decided to appoint a research committee with authority to plan and promote research work, securing the necessary funds to push the work forward, but without itself conducting the actual tests involved. It is understood that the Society will co-operate with the Bureau of Standards and the American Petroleum Institute in this connection. Mr. Vincent favors a campaign of education that will instruct the automotive engineer in matters pertaining to the oil industry as well as to keep them advised concerning the latest developments in fuel research.

In concluding his remarks, President Vincent spoke of the need of fostering aircraft development not only in commercial lines but as a means of developing personnel that will prove a military asset in case of need.

Treasurer Whittelsey reported that the total assets of the Society are in excess of $150,000, these assets having increased by over $30,000 during the fiscal year ending Sept. 20, 1920. Over $22,000 was spent for standardization work last year.

Chairman Beecroft of the Meetings Committee reported that the total attendance at Society meetings last year was about 2500, and that 88 papers had been presented at the various meetings.

The Membership Committee reported an increase of 16 per cent in the membership during the last year, the membership as of Jan. 1 being 5231.

In the report of the Council it was brought out that the Society expends annually over $58 per member, although the dues for member and associate grade are only $15 per year.

The business session was concluded with talks by Henry M. Crane and Herbert W. Alden on the engineer's place in the industry. Mr. Crane held that it was the duty of the engineer to know not only the principles of the vehicle he designs but the principles of production of the various parts in order that these may be intelligently designed for economical output. He stated also that the engineer must be conversant with what the public wants in order that the vehicle produced will be readily salable; this, of course, involving co-operation with the sales department. Mr. Alden indorsed Mr. Crane's remarks and indicated that the value of an engineer and his standing in any organization is usually dependent upon his ability to co-operate and willingness to accept responsibility. He urged greater thoroughness in making investigations and a merging of individuality with a view to serving all departments of the business.

The tellers appointed to canvass the mail vote covering

annual election of officers reported that the ticket named by the nominating committee had been almost unanimously elected. President-elect Beecroft thereupon acknowledged his appreciation of the honor conferred upon him and pledged his best efforts in advancing the work of the Society during his administration.

David Beecroft, the new president of the Society, is Directing Editor of the Class Journal Company. The following biographical sketch is furnished by the Journal of the Society:

President Beecroft was born in 1875 at Marnock, Ont., Can. His business life started in 1893 when he taught a country school for one year previous to finishing university work at the Barrie Collegiate Institute. This was followed, beginning in the fall of 1895, with a six-year period of school teaching in St. Thomas, Ont., during most of which time he was connected with the editorial department of the St. Thomas *Daily Times*.

Leaving St. Thomas in the summer of 1901, he went with the Chicago *Daily News* as an advertising solicitor, remaining until December, 1902.

In December of 1902, on resigning from the Chicago *Daily News*, he took the editorship of the *Automobile Review*, which was until then a monthly automobile publication printed in Chicago. It was at once changed to a weekly, and he continued there for about fifteen months, resigning on March 1, 1904, to take the position of assistant editor of *Motor Age*. He served for two years in this capacity, and when *Motor Age* was purchased by the Class Journal Co. of New York he became editor.

In July of 1911 he took, in addition to the *Motor Age* work, the position of managing editor of *The Automobile*. In November of that year he also became managing editor of *Commercial Vehicle*, and in February of 1914 he took a similar position with *Motor World*.

Since entering the automobile industry he has been particularly active in connection with automobile contests. He drafted the first stock car racing rules and pioneered the registration of stock cars. He has served on the A. A. A. Contest Board for many years.

Mr. Beecroft became a member of the Society in 1911 and has served on the Council for four years. He has been a member of the Meetings Committee for five years and its chairman for four years.

A Brilliant Annual Dinner

By Clyde Jennings

THE chief feature of the successful annual dinner at the Hotel Astor was the introduction of C. F. Kettering as toastmaster, upsetting the long established precedent of employing a professional for that task. It is a safe probability equation that the membership will never vote to go back to the paid individual. This is said without casting any aspersions on the former toastmasters, who were very good in their way but who sometimes displayed a lack of exact understanding of the industry from an engineering point of view. With Kettering, of course, it was a case of entirely co-ordinated knowledge and jokes, with an ability to pass compliments and criticism, founded both on fact and personal friendship, backed by an ever ready wit and novelty of expression.

President Jesse G. Vincent opened the program by reviewing in few words the year just closed. He spoke especially of the fine support given to the officers of the Council and the members, and said that if the members and the Council would continue this same measure of support he knew that the new administration would prosper. He introduced Mr. Kettering.

The toastmaster had much sport with David Beecroft, the newly elected president, whom he introduced. He said that the society had run out of engineers for president, so they had done the next best thing and had followed the trend of fashion and had selected an editor.

President Beecroft in a brief speech made the points that the engineers of this country had accomplished a great task in taking the vehicle as developed in Europe and making an efficient production job of it. This was the task for American engineers because production was the great need of this country.

Now that this task had been accomplished, there remained the task of adapting the vehicle to the great uses of the world. This problem was before the engineers and the speaker thought it necessary that the engineers go to all parts of the world and study the needs of the vehicular transportation where the vehicle will be used and design accordingly. When this is accomplished, he said, the great world's markets will be open to American manufacturers, and this in turn will profitably utilize the expanded manufacturing space that was bequeathed to the industry through the war.

Much interest was shown in the talks of the evening. R. E. M. Cowie, vice-president of the American Railway Express Co., introduced himself as the representative of the largest motor truck operator in the world. After reviewing the history of the express business, and its growth, he put before the engineers the problem of simplified construction and a smaller maintenance cost for their vehicles. He said while the internal combustion engine and its consequent vehicle might not appear complicated to the engineer, it did appear so to the user.

But it was when he touched upon aviation that the speaker most impressed his audience. He spoke of the great need for the faster transportation vehicle and said that he was one of those who believed that the Government should go to full length in developing this means of transportation. He said that the small beginning made in airmail experiments were only a taste of what should be done and that he hoped that in the near future the Government would supply for air transportation all that it was now supplying for marine transportation.

Following this talk, Toastmaster Kettering made a plea for more members for the Aero Club of America, which, he said, had been transformed into an organization of great possibilities and promise, with Myron T. Herrick of Ohio as president.

George E. Roberts, a vice-president of the National City Bank, was the last speaker. He is not one of those who promise great prosperity for the immediate future, but told how production had been thrown out of balance during the war and even to a greater stage since the armistice. The great problem now, he said, was to restore this balance. This had been the objective of the bankers in their credit adjustment beginning almost a year ago.

At present, he said, the price on farm products had been restored to a near normal point. Because of the great bulk of business depending upon the prosperity of the agricultural interests, it is necessary to adjust the manufacturing prices and industrial wages to a balance with the farm prices.

Observations at the New York Truck Show

Few changes of a radical nature in evidence. Influence of war designs seen in fitting of bumpers and tow hooks on many models. Flexible frame a feature of Ward-LaFrance. Most heavy trucks use radius rods, but take torque on springs. Many models have improved facilities for lubrication of chassis parts. Closed cabs are fitted in many cases.

By P. M. Heldt

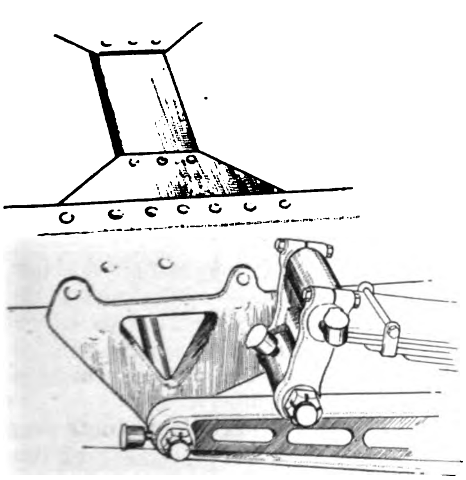
ALTHOUGH it was held in two large buildings—the Twelfth Regiment Armory and the First Field Artillery Armory—the New York motor truck show was not a national or a manufacturers' show, but rather a dealers' show, and many of the most prominent truck makers, such as Packard, Pierce, Mack, White, Autocar, etc., were not represented. However, there was a sufficient array of trucks of all capacities to make an interesting exhibit. A few truck models, mainly of the speed wagon type, were shown the first time, but on the whole novelties were not particularly plentiful.

Truck design is not stationary; that it is progressing could easily be demonstrated by showing side by side a number of 1910 and 1921 trucks. However, most frequently the changes are matters of detail and can hardly be observed on the complete truck, while more important changes or complete redesigns often are separated by intervals of years.

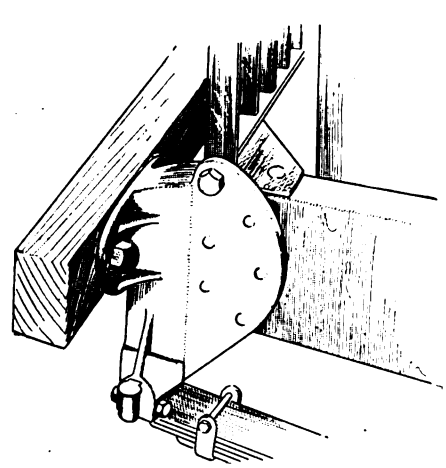
Frame Design

One important problem in connection with motor trucks is the design of the frame. It is fully recognized that it is impossible to make the frame rigid, as it is a flat structure and has to support heavy loads, the dead load, moreover, being augmented by road shocks. Flexibility of the frame is therefore allowed for, especially weaving of the frame, which means twisting around a longitudinal axis. In view of the absolute certainty of weaving occurring in service, both the engine and the transmission (where the latter is mounted separately) are now always mounted with a three point support. It has been found that, owing to the continuous distortion of the frame and the shocks and jars to which the chassis is subjected, the trunnion support wears more rapidly than might be expected, and this gives rise to an unpleasant chatter. To minimize this wear these trunnion supports are now made of much larger diameter (about 3 in. on large units) than formerly. In the most careful designs provisions are even made for readily adjusting the trunnion in case of wear.

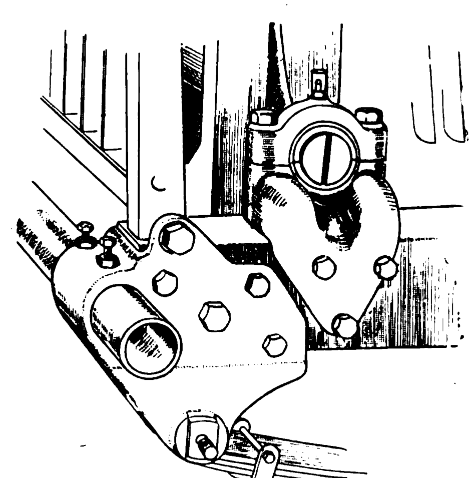
Some designers specially aim at great flexibility of the frame in a vertical direction and in the new Ward-La France truck there are no regular cross members, only tubular spacers. To secure the necessary stiffness or resistance to distortion in a horizontal plane two diagonals of strap iron are used at the middle part of the frame, the junction of these members being reinforced by a drawbar and tubular spacers. Such diagonal braces are also used on other makes of trucks, usually at the rear end. They obviate the necessity for heavy gusset plates and are probably more effective. Some truck frames were noticed in which practically no provision was made against distortion in a horizontal plane; that is, there were neither diagonals nor substantial gusset plates, and the cross members were few and light. There is no doubt that such construction is responsible for many breakages of engine arms and trouble with radiators. The necessity of making



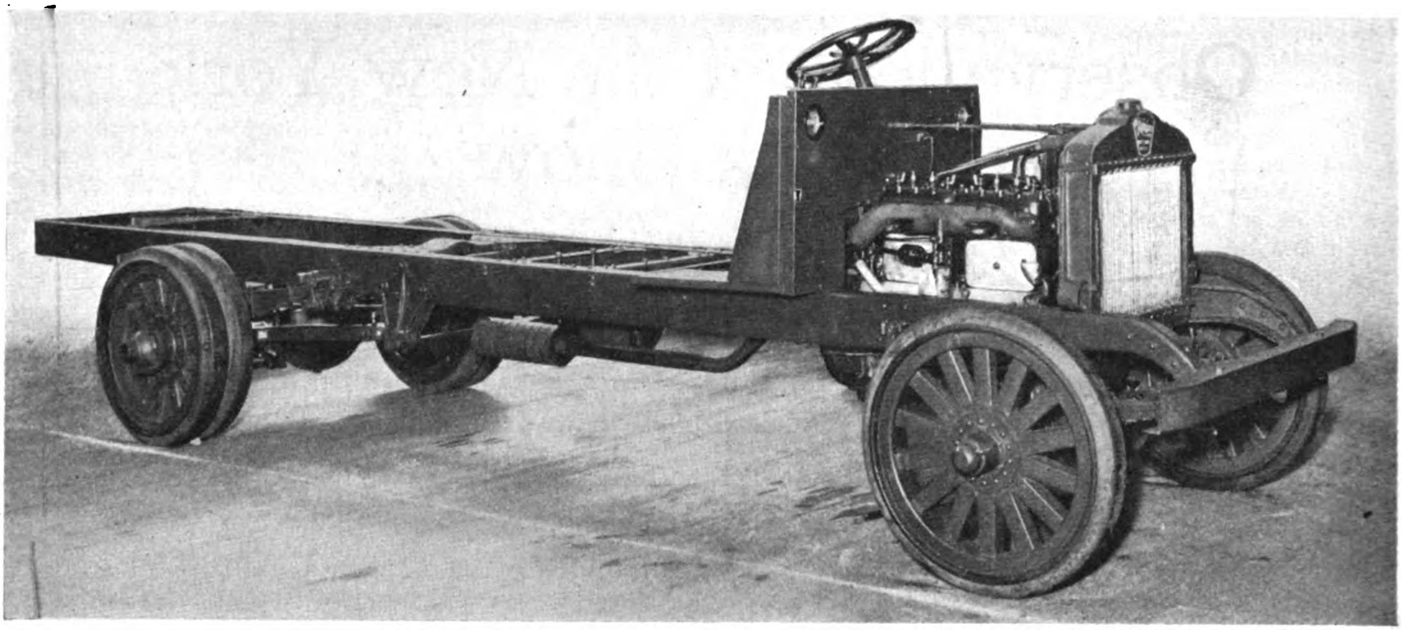
Central cross-bracing of frame on Clydesdale



Wooden bumper on Indiana truck



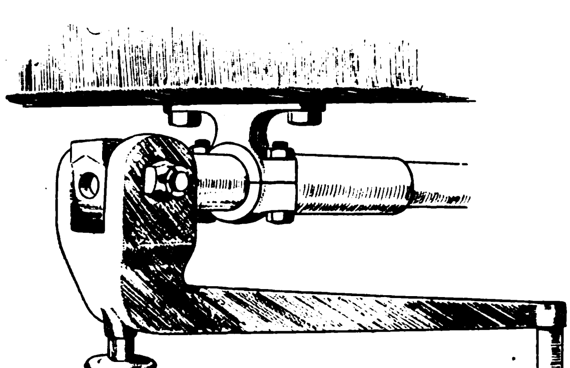
Combination spring and bumper bracket on Selden



New Rainier 3½-ton truck chassis

the engine supports flexible is realized more and more. In the new Service speed truck, for instance, all the engine holding down bolts have coiled springs under their heads, so that the supporting arms can withdraw slightly when the frame distorts. Also, in the heavier trucks it has now become the practice to use four universal joints, two between the engine and gear box and the other two between the gear box and rear axle.

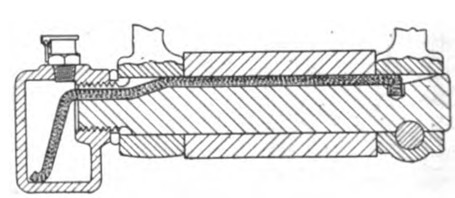
While military truck design has had some influence on commercial truck practice, it has not led to the general adoption of the Hotchkiss drive, as was predicted by some engineers. The general practice on heavy trucks appears to be to take the torque reaction on the rear springs but to provide radius rods for the driving thrust. An exception is found on the large Bridgeport truck. In this the drive is taken by the rear springs, whose forward ends are pivoted to the frame. Then there are members which look very much like radius rods, which are hinged to lugs on the forward side of the rear axle housing and to a bar which is adapted to slide forward and backward in a guide formed by a frame bracket. Radius rods generally have a universal connection with the frame at the forward end, an eye bolt parallel with the frame side rail being mounted in a frame bracket and having the forward end of the radius rod pivoted to it. This construction is evidently somewhat cheaper than a spherical joint.



Folding starting crank on Transport

Special attention was paid to the different ways of mounting the frame on the rear springs. The springs are always outside the frame, and owing to the overhang there is a considerable tendency to twist the side rail. In most cases the frame is provided with a cross member at the rear spring front brackets, which gives the necessary rigidity at this point. In the Clydesdale and one or two other makes this provision against torsional stresses on the frame side bars due to the overhang of the springs is particularly effective. The spring bracket and the bracket for the forward end of the radius rod are in one piece. The radius rod forward ends are pivoted on the ends of a round cross bar about 8 in. below the frame rail, and in addition there is a channel shaped cross member, with its open side down and with its top even with the top of the side rails. In some cases the rear ends of the rear springs are mounted on the ends of rather slender cross bars, and one could not help getting the impression that under heavy load these cross bars would "spring" considerably, which would mean rapid wear of the spring bushings. Of course, where the rear spring bracket comes close to the rear frame cross member, the latter may lend sufficient stiffness to the bracket in which the cross bar is mounted. However, a form of spring bracket which supports the spring bolt at both sides of the spring would be preferable even in that ease.

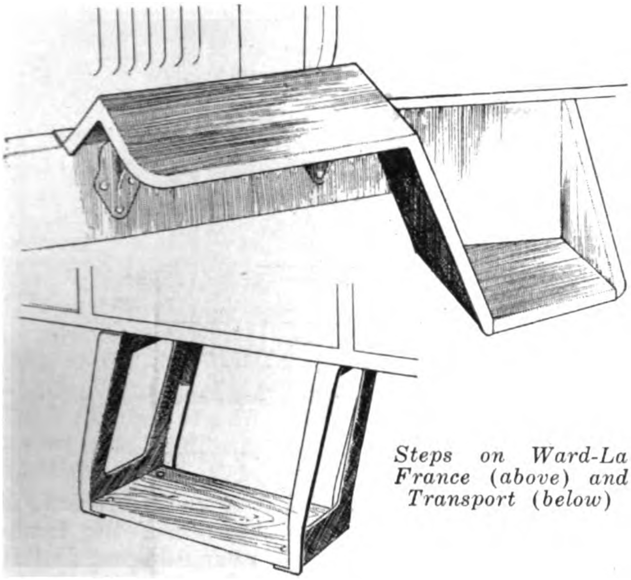
Wick-oiled spring bolt on Transport



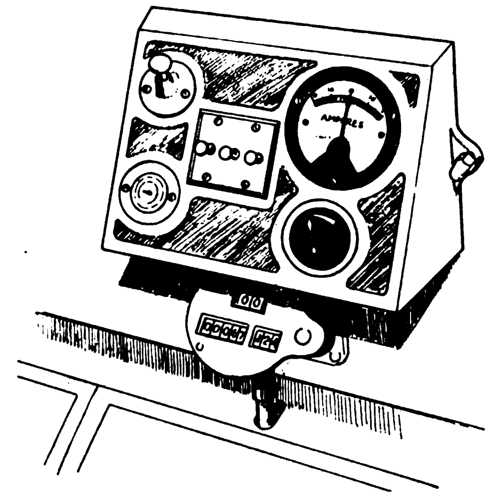
Trussed Frames

A large majority of the truck frames are now made of pressed steel, but the frame side members, as a rule, are tapered very little toward the ends, particularly the rear end. This is no doubt due to the different load distribution as compared with a passenger car. The Clydesdale was the only truck noticed in which there was considerable taper in the side members.

It is rather remarkable that not more trucks have their frames trussed, as quite a saving in weight could evi-



Steps on Ward-La France (above) and Transport (below)



Instrument panel on Clydesdale

dently be effected by the use of trusses. Frames of railway cars are always trussed, and of the German motor trucks surrendered to the American Army a large number had trussed frames, though it is possible that in the latter case the trusses were put on after the trucks were built, to take care of the additional stresses due to the use of wood and steel tires. At the show the only trucks with trussed frames noticed were Nash Quad and the Indiana.

Towing hooks are now fitted to the front ends of the frames of many of the larger trucks. These were required on all war trucks and were found a most handy fitment in an emergency. As they cost but little and as their usefulness must be apparent to every purchaser, it seems a good plan to make them a part of the regular equipment. Design of bumpers also has been influenced by war experience, and the latest Transport and Indiana models are fitted with wooden bumpers similar to that on the Class B war truck.

Brackets and Fittings

The brackets and fittings of truck frames are gradually getting neater, and quite a technique is developing in motor truck design. Some trucks are fitted with channel steel bumpers whose ends are curved slightly backward, and in that case the spring horns are formed with projections which accurately fit into the bumper channel. Combination brackets save on machining and are used largely for the forward ends of truck frames. An example of this is found on the new Selden model. A single casting serves as a spring bracket, bumper bracket and radiator guard bracket.

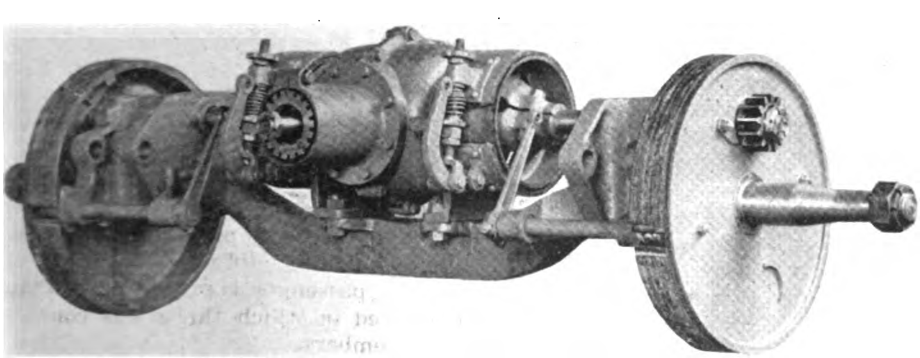
The Nash Quad, although not a new truck, arrests attention because of its many unusual features. Thus the half elliptic springs are very light, giving a very flexible suspension for relatively smooth roads, but in addition to these there are volute auxiliary springs, which share the load with the half-elliptics when unusually severe bumps are sustained.

There is considerable variety in the design of steps. The most common practice is to use two pressed steel hangers, and either a wooden or embossed metal step. On the Ward-La France truck, the step is made of pressed steel and forms a part of the front fender. Some manufacturers object to making the step a part of the front fender, arguing that the continued use of the step will tend to cause the fender to get out of shape. On the Transport truck the fender consists of two cast hangers riveted to the frame and an easily renewable wooden step. Wood for the step has the advantage that it does not get slippery with wear.

New Type of Internal Gear Drive Axle

The Kelly-Springfield Motor Truck Co.—now a part of Hare's Motors—exhibited a new 3½-ton model with an overhead type of internal gear drive rear axle. Heretofore the chain drive has been standard on Kelly-Springfield trucks. The new axle, which is made for the Kelly-Springfield by the Clark Equipment Co., has a chrome nickel steel supporting member with a downward bend at the middle, which is forged with lugs to which the housing of the differential and bevel drive gear is bolted. From this housing extend the jackshafts which do not have the usual tubular coverings but instead carry drums for the service brakes on both sides of the housing. This model now also has a four-speed and reverse gear, while the engine remains the same. The torque reaction is taken on the springs, while the drive comes on the radius rods.

Among the models exhibited for the first time was the Moline 1½-ton truck, which has the same engine as the Moline Universal tractor. This engine has its valves in the head and the valve cover is water jacketed, which permits of arranging the water outlet centrally on top of the engine as in an L or T head engine. This is specially desirable in the present case because thermo-siphon circulation is used. Formerly the piston pins in the Moline engine had a bearing



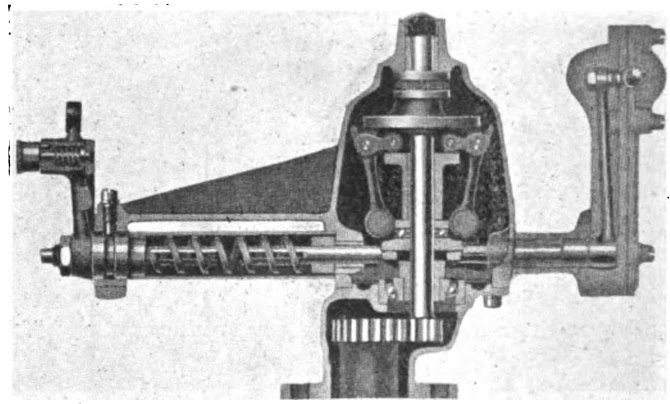
Clark overhead drive internal gear axle on Kelly-Springfield truck

directly in the piston bosses, but now the bosses are bushed. Instead of the Remy electric control system, the Pharo governor is used. Ignition is by a Splitdorf magneto. The pressure gage and the throttle control lever are mounted on a fixture on the steering post so they are in plain sight of the operator. The choker can be operated both from the dash and from in front of the truck. This is convenient in cold weather, when the driver sometimes wants to partially close the choker when the engine is still cold and therefore operates irregularly. Circulation of the cooling water is by thermo-siphon action, and the radiator fan is enclosed in a shroud. Fisk pneumatic cord tires are fitted all around. The wheelbase is 130 in. and the weight of the chassis complete is 3635 lb. The rear system is the Torbensen internal gear drive. The four cylinder Moline engine has a bore of 3½ and a stroke of 5 in. The crankshaft is exceedingly robust, being 2½ in. in diameter, and the connecting rod head is of such large size that the piston and connecting rod cannot be withdrawn from the engine through the cylinder when the cylinder head is taken off, but must be removed from below.

A new line of trucks, exhibited for the first time, was the Clinton, manufactured by the Clinton Motor Truck Corp. This line comprises four models, of 5, 3½, 2½ and 1½ tons capacity, respectively. Standard parts are used throughout, including the Continental engine, Brown-Lipe clutch and change gear, Timken axles, Parish & Bingham frame, Spicer universal joints and Ross steering gears.

On one model of the Clydesdale was shown a pair of electric headlights of rather unique design. These were pyramidal in form, with an octagonal front, and bolted to the sides of the radiator. On this same model there was a neat instrument panel secured to the dashboard (see sketch). The instrument panel was slanted so as to give the driver a good vision of the instruments, and contained the ammeter, oil gage, magneto lock switch, lighting switches and choker.

On some makes of motor truck the starting crank is supported by a bracket bolted to the forward end of the engine crankcase and is then sufficiently far back so it will not be injured when the truck runs into an obstruction. On other trucks, however, the starting crank is carried by brackets under the front cross member of the frame, and in this case the starting crank, when in its operating position, is the most forward portion of the truck, hence, is easily injured. In that case it is necessary to give the crank a folding or swiveling form, and fold it out of the way when not in use. On the Indiana truck, for instance, the starting crank is carried in a swivel bracket, depending from the forward cross member of the frame, and when not in use, the crank is swung around and its arm is held by a clasp in such a position that the whole crank lies horizontally. On the Transport truck (see sketch) the crank can be swung around through an angle of 90 deg. and locked in both the working position and the position of rest, by means of a spring latch.

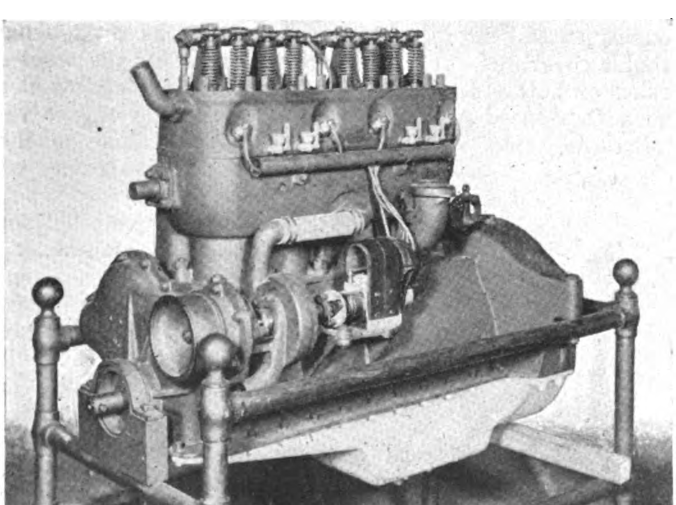


Section of Hinkley governor

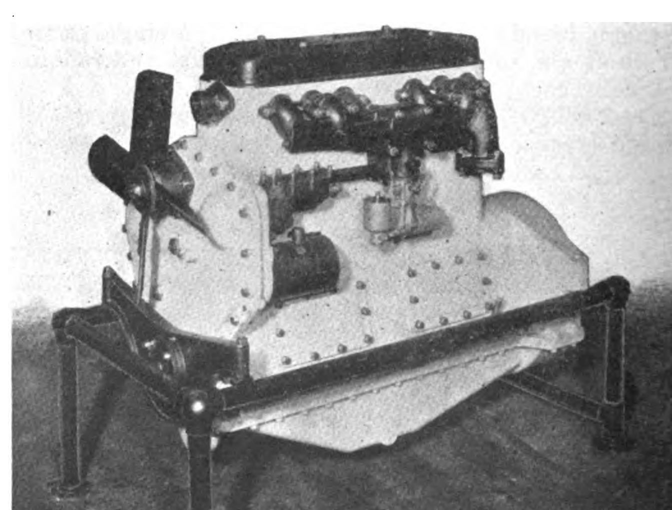
Improved Chassis Lubrication

Much attention has been given in recent years to the subject of chassis lubrication, and many trucks exhibited at the show were provided with either the Alemite system of grease lubrication, or with a wick oiling system. On the Transport truck, for instance, the spring bolts are provided with an oil chamber at the outer end, into which extends a wick which passes through a slot in the bolt, extending practically the entire length of same. On the 3½-ton Transport model, these wick oilers on the spring bolts are intended not only to lubricate the spring bolts themselves, but also the spring leaves.

The Hinkley Motor Corp. exhibited for the first time the model HA-1600 truck and tractor engine, which is of the overhead valve type. This has a bore of 4½ in. and a stroke of 5½ in., giving a displacement of 352 cu. in., and weighs approximately 900 lb. The oil pan is of aluminum and has an oil capacity of 8 qt. A chrome nickel steel crankshaft is used. Provision is made for both magneto and battery ignition, and also for an electric starter and generator. The engine is provided with an SAE No. 2 bell housing. Three point support is used, there being a large trunnion



Hinkley overhead valve engine



Van Blerck truck engine

bearing at the front end. Lubrication is by the force feed method, a gear pump being mounted in the oil pan below the oil level. Any standard make of carbureter can be fitted, in conjunction with a hot spot manifold.

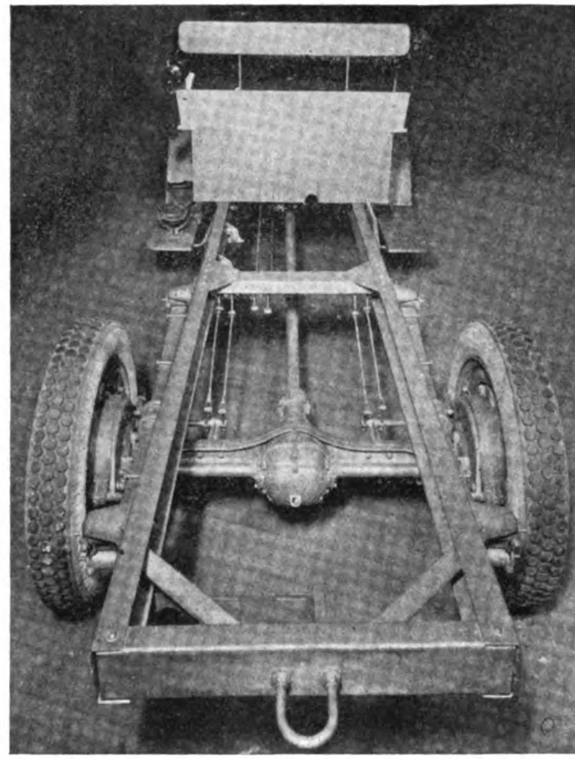
Hinkley Governor

The feature of the new engine is the governor, which is original with Mr. Hinkley. It is of the flyball type, and is mounted at the rear end of the engine, being geared up from the camshaft. The governor has four flyballs, which revolve on a vertical axis. The centrifugal force on the flyballs is counteracted by a coiled torsion spring, acting through a lever on the sliding collar of the governor. The outer end of the torsion spring is secured to the hub of an adjusting lever, which is adapted to move over a sector with a number of adjustment holes in it. Thus the governor can be readily set to hold the engine down to any maximum speed within wide limits. The governor is very sensitive, and when set in any definite position, controls the speed of the engine within narrow limits between no load and full load.

An exhibit was also made of the Van Blerck engine, which was described in these columns last winter, at the time of the Kansas City tractor show. This is an engine designed for use as a tractor, marine or truck engine, certain features being made differently for the different applications.

The Parish Mfg. Co., manufacturers of pressed steel frames, showed a complete truck frame of alloy steel. This company is now prepared to furnish frames of molybdenum steel, which when properly heat treated is said to have an elastic limit of 150,000 lb. per sq. in.

A large proportion of the heavy trucks exhibited were shown with closed cabs, and there is little doubt that these cabs will become a standard feature of truck construction in the future. These cabs are fitted with windows all around, so as to allow the driver free vision in all directions, and they enable him to operate his truck in comfort in all kinds of weather. Provision is made to open practically all of these windows in mild weather, and the driver therefore need never be without fresh air. It is now customary to mount the headlights inside the cab, against the rear side of the dash. This has the advantage that the lamps throw some light through a side lense on the dash, making it easier for the operator to read his instruments in the dark, and in the case of kerosene lamps, which are most generally used, there is no danger of the lamps blowing out in stormy weather.



Rear view of Moline speed truck chassis

In addition to complete trucks and chassis, there were shown a number of trailers and truck bodies, as well as several exhibits of truck parts and accessories. Prominent among the latter were traction devices and chassis lubricating means.

A Winter Truck Cab

WITH the increase in long distance hauling and trucking, and realization of the need of weatherproof cabs in winter time, these units are rapidly being developed. The Acme Motor Truck Co. has just brought out a standard winter cab which can be furnished on all of its models. It is so designed as to preserve the lines of the vehicle and it is recommended for use with the Acme truck because of its better fit and blending of lines with body.

Winter top for Acme trucks

This new cab is constructed of oak and built around the regular seat box. It is completely ironed at points of stress and designed to stand up under rough service. The side sections are constructed of waterproof veneer panels, curving toward the rear with a sheet metal corner construction running full height. An opening 5¾ by 11¼ in. is provided in each corner. This is fitted with Pyralin so the driver has a clear view of traffic approaching from either side. The back of the cab is fitted with sliding windows which can be opened or closed for ventilating purposes. Each of the side panels has a 6 by 11 in. Pyralin light. The doors run full height of the cab and have a 9 by 11 in. Pyralin light which can be increased to approximately 10 by 15 in. The doors swing toward the front and are provided with anti-rattle locks. The top of the cab is built of ribs and slats covered with a heavy grade of oil duck.

The general dimensions of the cab are as follows: Width, 48 in.; height from top of frame, 61 in.; depth from front to rear, same as on standard models; height from top of cushion to inside of roof, 40 in.; length of ventilating windshield, 41¼ in.; height, 23½ in. The list price of this winter cab is $125.

Drop Forgings in Automobile Construction

METAL parts in automobiles or other machines can be made by several different processes. We have first of all castings, which are used to a considerable extent in the engine and also for many of the more complicated parts of the chassis. Then there are drop forgings which include practically all parts made of mild steel and medium carbon steel except those which can be advantageously made from sheet or bar stock. Rods, shafts, studs, bolts, etc., are made from bar stock and numerous housings, covers, etc., are pressed from sheet steel.

In passenger car practice the parts which are made by each of the different processes are pretty well fixed. These cars, or the components of which they are assembled, are as a rule made in sufficient numbers to warrant the making of dies, the expense of which sometimes militates against the adoption of drop forgings when only a moderate number of parts is wanted.

In truck manufacturing drop forgings are not used to quite the same extent as on passenger cars, and in tractors their use is still less common. Tractor manufacturers of the old school use rolled section steel, mainly angles, very largely, but there is no doubt that when tractor design becomes more settled drop forgings will be almost as numerous in the tractor as they are now in the automobile. When required in sufficient numbers, drop forgings can often be made more cheaply than castings. They require no straightening, there is not much loss from imperfect forgings and the parts are usually stronger and more reliable than when cast. The majority of drop forgings are made of medium carbon steel, but for parts subjected to high stress the forgings can be made of alloy steel.

The extent to which drop forgings are used in car construction is shown by the following list of forgings for a four-cylinder car. The list includes 122 different parts and 190 pieces. The Packard passenger car, for example, contains 200 forgings and the Packard truck an even 250 forgings. In the Packard passenger car there are, moreover, 175 stampings and 240 castings. For the following list we are indebted to T. W. Siemon of the Union Switch & Signal Co.

No. of Pieces	ENGINE
1	Crankshaft
4	Crankshaft counterweights
1	Crankshaft drive gear
4	Connecting rods

Accurate Methods in Keeping Stock Records

A stock keeping system proves itself good or bad when called upon to meet a real test. The system described in this article was able to tell within three days every article that a large fire had consumed. Accurate stock records are especially necessary in these times of business economy.

By Fred J. Huntley*

ON Christmas Day building No. 11 at the main plant of the Cadillac Motor Car Company in Detroit was destroyed by fire, and with it went great quantities of supplies and tools. On Monday following, just three days later, A. M. Elmer, superintendent of general stores, was able to report the exact value of all property lost.

This may seem at first thought almost like a bit of fiction, but it is true. And, furthermore, if fire again should visit the plant, an equally prompt report would be forthcoming. The records were so complete and so satisfactory that the company had no difficulty in settling this particular loss.

But this is not all there was to that Cadillac fire. Certain of the equipment in this building was covered by separate records kept by an old pen-and-ink method. When the adjusters reached these there was a different story and considerable delay resulted before everything was straightened out. The Cadillac Motor Car Company is not the only concern that has had experience with stock records when fire has stepped in. Many have experienced days and even weeks of delay with the inevitable accompanying loss, simply because their records were inadequate.

To give a clear picture of the way posting is handled and what constitutes the posting media in keeping Cadillac stock records, it will be best to trace a requisition and purchase order through the various steps.

Posting to the "Incoming" or debit side of an account is made from "T-requisitions" on the Purchasing Department and also invoices. The posting media for outgoing material include inter-plant transfers, requisitions, inter-department transfers and sales orders. Since requisitions make up the bulk of posting, it will be well to tell first how they are handled. To begin with, they are made in quadruplicate and then sent to an "Approval Clerk," whose duty it is to look up the stock sheet for the item ordered. If it is stock, the clerk sends the triplicate to the stockroom, where it is authority for making the delivery. The second copy goes to the factory Accounting Department, and the original is used as a posting medium. This the clerk inserts next to the account affected in the ledger tray.

When a sufficient number of requisitions have thus been "stuffed" into the ledger tray it is sent to another girl who figures the value of the articles requisitioned. As the work is done on a machine, it only takes a few seconds to make the extensions. The tray then is sent to the posting clerk. Debits and credits are posted in separate runs. The requisition is posted to the credit side of the quantity record and also to the value record.

After posting debits, the clerk locates the first account with a credit to be posted, designated by the requisition "stuffed" alongside. Thus it only takes a second or two to handle each item.

Since no posting is to be made to the "On Order" record, the sheet is turned so that the bottom half is in printing position. Date, classification, department letter and number are posted in one operation. The machine carriage then moves into position where the old balance is printed. Since there is no debit entry, the carriage is moved to the "out" position, where the withdrawal is listed and automatically subtracted. The new balance, which has been extended automatically, is printed in the "on hand" column and the carriage is shifted into the "value section." Here again the old balance is picked up; then the unit value shown on the last debit entry is listed. The credit as shown on the requisition is entered and the new balance extended. This done, the sheet is restored to the tray and the requisition turned face downward. This procedure is followed until all credits have been posted.

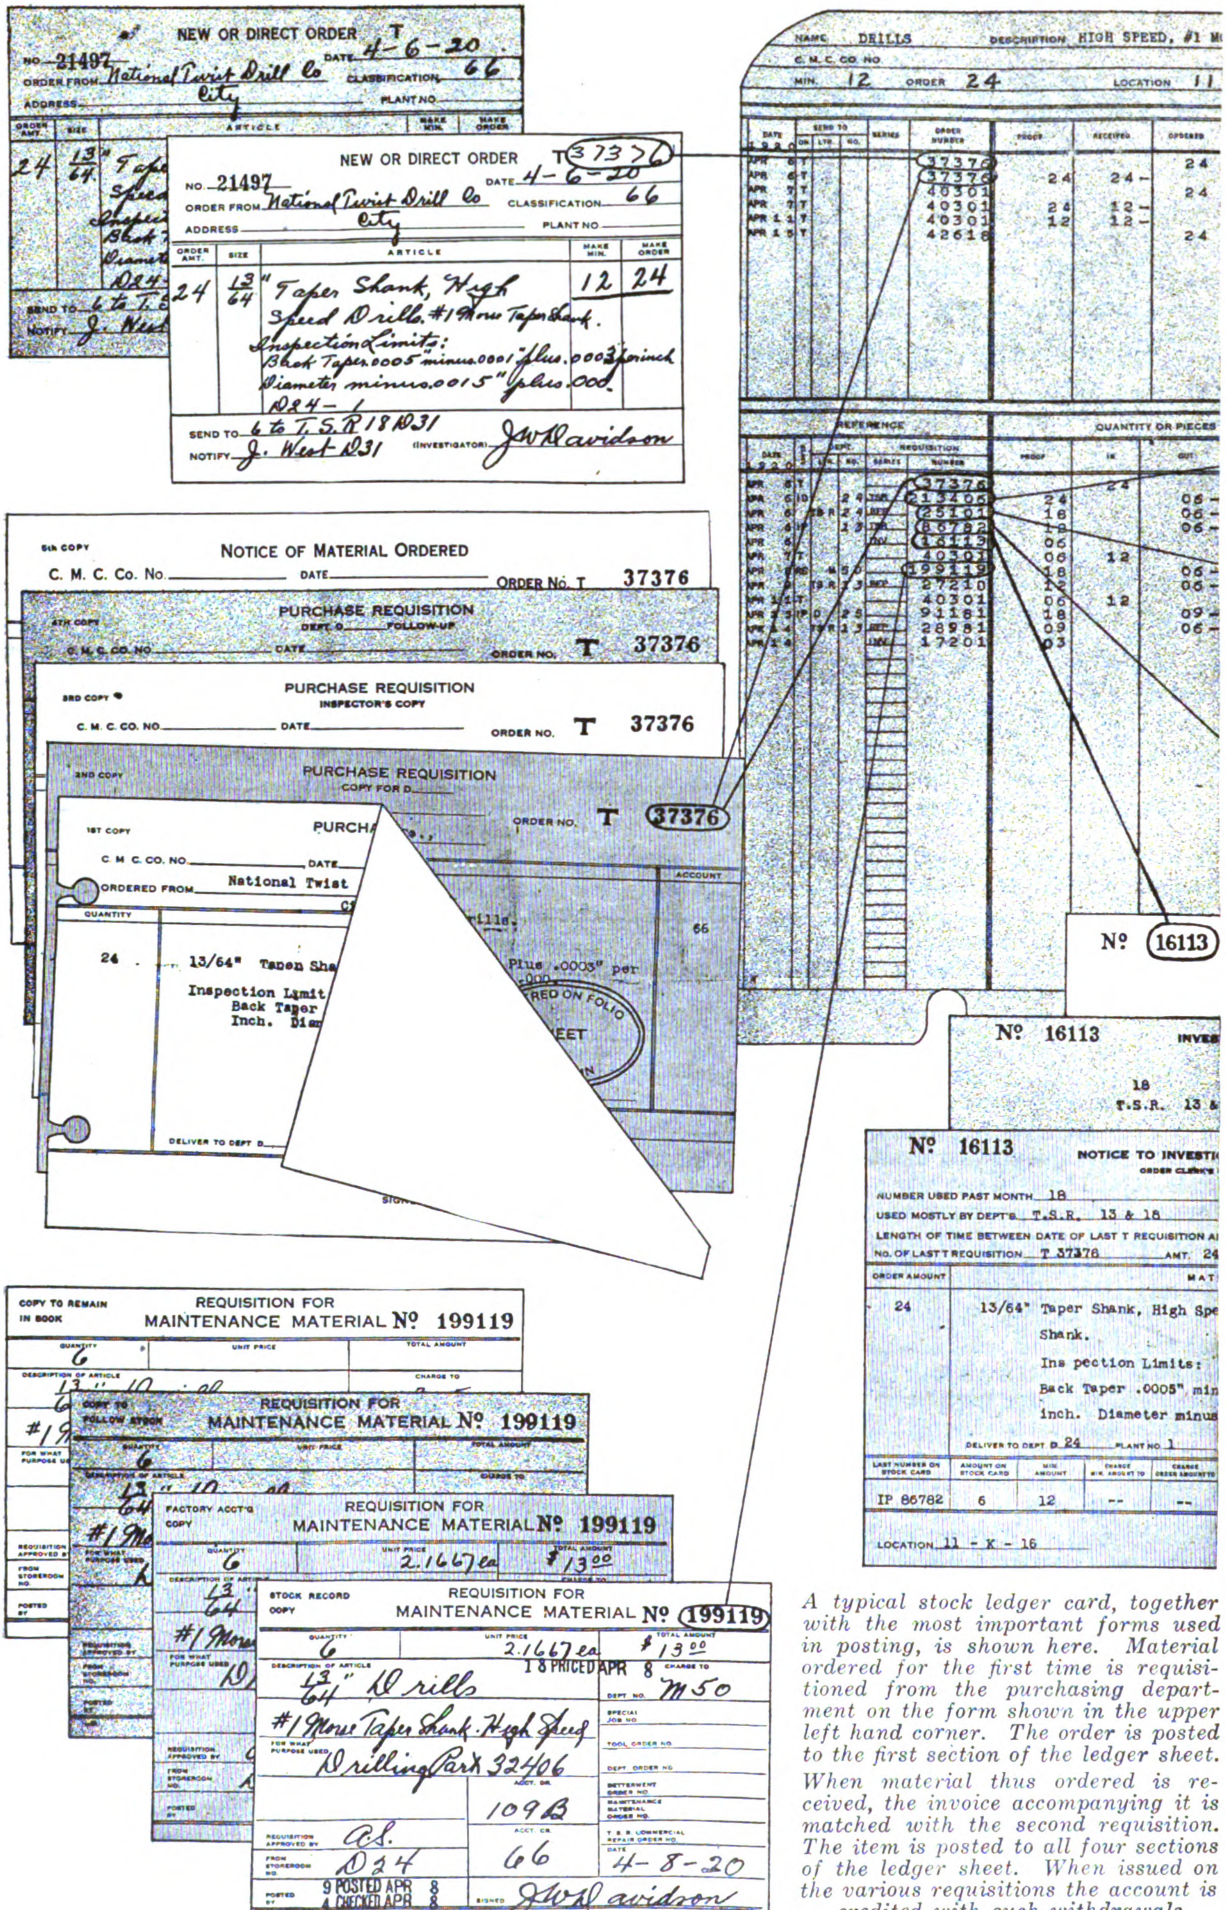
As the debits already have been posted, the tray is sent to a girl whose duty it is to prove the work. She does this by multiplying the quantity on hand by the unit value and if the results check with the new balance in the "value section" she knows the account has been posted correctly. She also makes sure that the entry shows the proper department and reference number. Now as to the case of a purchase or debit. When the girl, in pricing outgoing material, discovers that this issue will reduce stock beyond the minimum shown at the top, she inserts a cardboard slip with the warning, "Stock below minimum."

After a tray has been posted a girl looks it through for these "low water marks" and writes a "notice to investigate stock." The warning then is turned upside down where the printed line "Notice Written" is shown. The notice finally goes to an investigator, who ascertains the probable demand for this item and the length of time required to replenish the stock, also the approximate cost. If the facts warrant, he directs on his report that a new minimum be set or that the quantity ordered be changed.

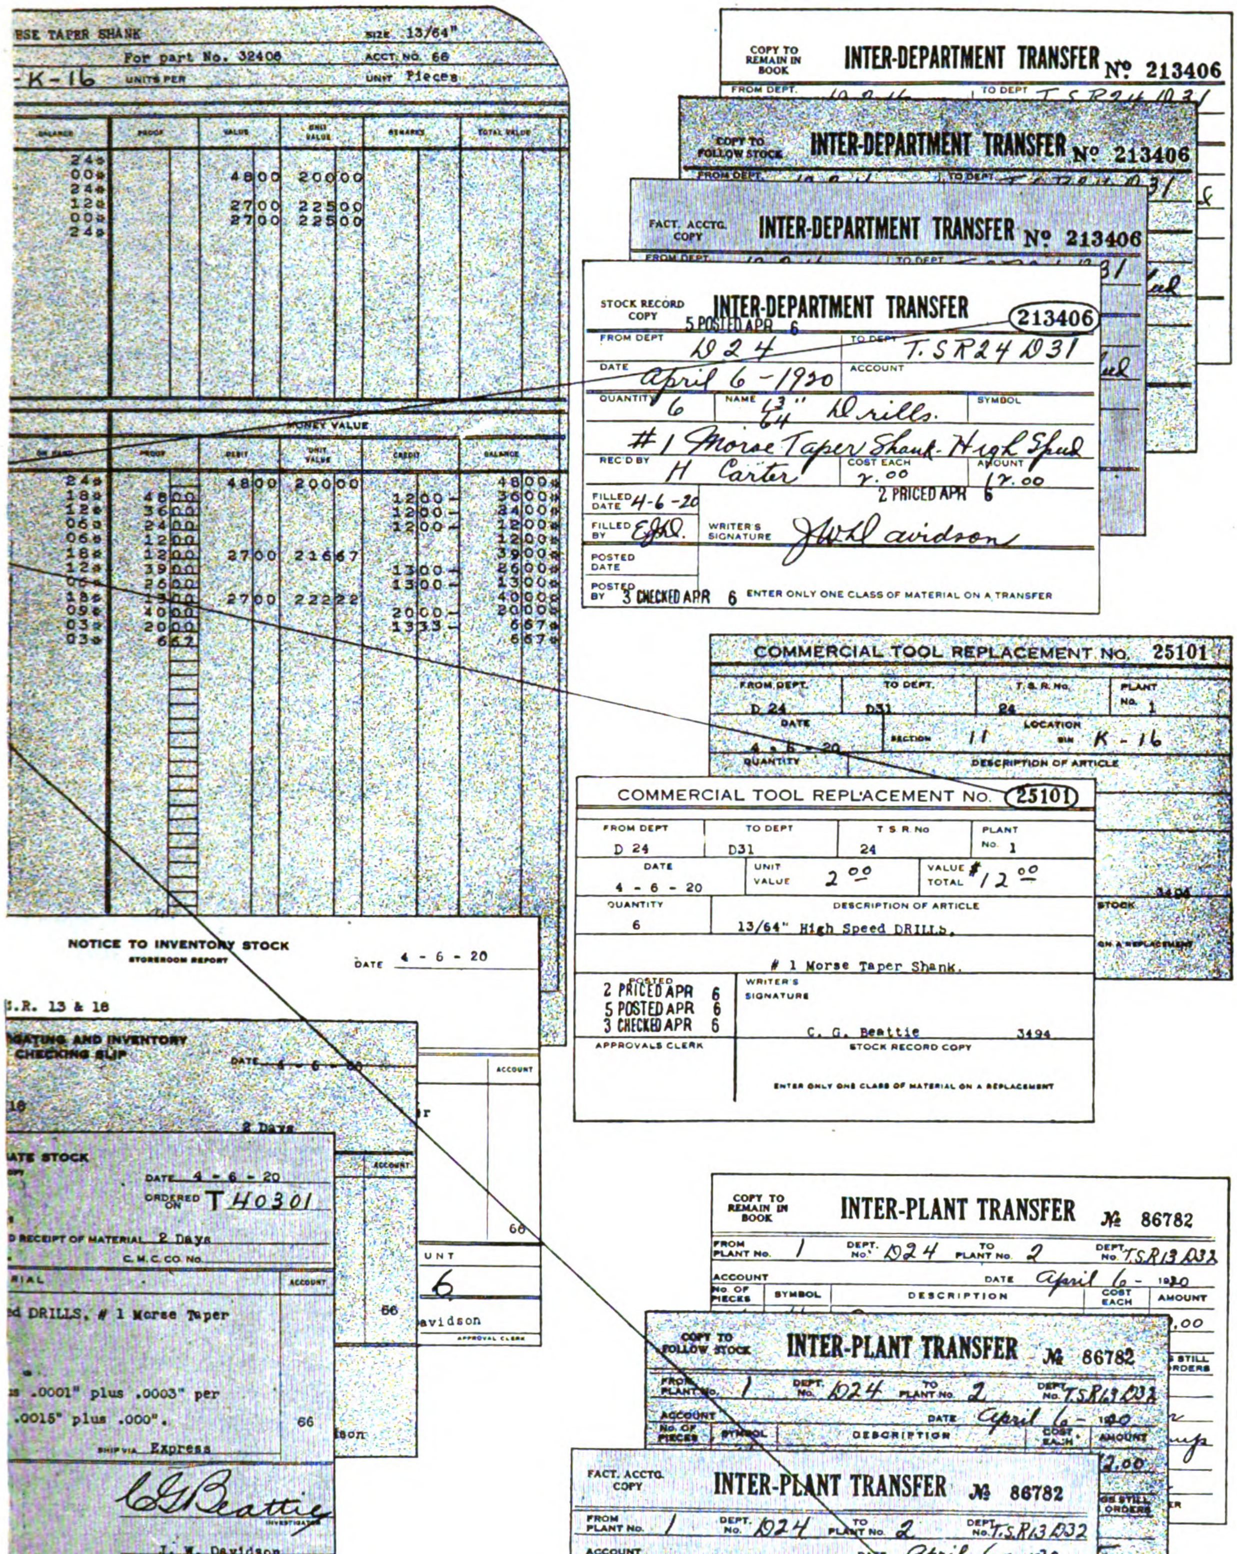
When this report is received a "T-requisition" is written and, if approved, the "T-requisition" is posted. The posting in this case is to the "On Order" section of the stock ledger. This purchase requisition is "stuffed" in the ledger and is posted as a debit. The "Notice Written" strip then is removed and the requisition is sent to the Purchasing Department. The third copy of the requisition is a "Notice to Inventory Stock" and goes to the stockroom, where a physical inventory is made of this item. This constitutes the only inventory the Cadillac Motor Car Company takes of tools and maintenance material.

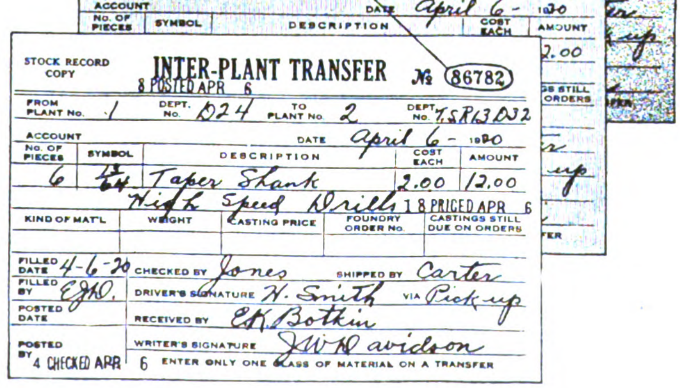
When material is received it is checked by an inspector, and a copy of the purchase order is matched with the in-

*Advertising Service Division, Burroughs Adding Machine Co.



A typical stock ledger card, together with the most important forms used in posting, is shown here. Material ordered for the first time is requisitioned from the purchasing department on the form shown in the upper left hand corner. The order is posted to the first section of the ledger sheet. When material thus ordered is received, the invoice accompanying it is matched with the second requisition. The item is posted to all four sections of the ledger sheet. When issued on the various requisitions the account is credited with such withdrawals





The price clerks, posting clerks and checkers stamp these orders so that any error may be traced. Checking methods play an important part in the efficiency of the stock record. Burroughs calculators are used in figuring of extensions and proving of postings.

The "Notice to Investigate Stock" is written when the posting clerk has called attention to the fact that stock is low. The triplicate is returned after the stock clerk has made an inventory of this item, and his report is checked by perpetual inventory clerks with the ledger account

voice and receiving slip, and goes to the invoice clerk to be "stuffed" into the ledger.

The clerk first figures the new unit value by dividing the balance on hand in money value by the new balance on hand in pieces.

The posting clerk enters receipts in all four sections of the stock account. The quantity received first is posted to the "On Order" section, and the new balance on order extended. The money value and the unit value of the items on the invoice then are posted. The sheet next is turned up and an entry made in the quantity section, the new balance being extended. Finally the value section is posted and the new balance extended. The new unit value as shown on the slip also is listed. When a tray is finished and the clerk encounters such an entry, she proves the work by multiplying balance on hand by the new unit value.

The accounts are carried on heavy loose-leaf sheets kept in steel trays. Each sheet has four divisions so as to show a record by quantity, a record by money value, the quantity on order and the value of each invoice. There are thirty-six trays—twenty-seven for plant one, six for plant two, two for plant three and one for plant four. Various colors are used to indicate the plant or department where the stock listed on each sheet is located.

The machine repair accounts are filed numerically, a code system being employed so that the number indicates style or type and size of machine. Commercial tools and supplies are filed alphabetically. In order to standardize the description of each item, a "specification" sheet is carried with each group of accounts listing similar articles.

As soon as the work of gathering the necessary information is completed, these specification sheets will show every department and operation requiring the tool or material described. This will serve as a guide in buying, because the probable requirements may be easily ascertained from the departments listed.

Steel Chart for Engine Manufacture

IN the design of gas engines it is essential that the material selected for the various parts be of a grade best suited to withstand the stresses to which that particular part is subjected. Much has been written about the advantages of the different steels, but very little about their specific use. In the accompanying chart the grades to be used for the parts of an engine are arranged in a convenient form, together with their physical properties and proper heat treatments. The chart was compiled by E. Everett Buchanan.

Parts	*Material*	*Physical Min. Requirements Lb. per Sq. In.*	*Heat Treatment Deg. Fahr.*
Carbonizing stock Camshaft Cam follower Thrust bearings Cold drawn tubing	Carbon, .10-.20 Manganese, .30-.60 Sulphur, .040 max. Phosphorus, .045 max.	Scleroscope, 75 For tubing— Ultimate, 55,000 Yield, 35,000 Compression test must show no cracks	Carbonize 8 hrs. at 1650-1700, cool in pots Quench 1650-1675 Quench 1450-1475 Draw 300 or more
Sheet steel Push rods Rocker arms	Carbon, .20-.30 Manganese, .30-.40 Sulphur, .045 max. Phosphorus, .045 max.	Ultimate, 60,000 Yield, 40,00 Elongation, 1 Reduction area, 50%	Quench 1540-1660 if necessary Anneal?
Water pump shaft nuts, etc.	Carbon, .30-.40 Manganese, .50-.80 Sulphur, .045 max. Phosphorus, .045 max.	Ultimate, 90,00 Yield, 60,000 Elongation, 15 Reduction area, 50%	Quench 1530-1570 Draw 950-975
Cylinder studs Main bearing studs Engine bed bolts Connecting rod bolts All other bolts Gears	Carbon, .25-.35 Manganese, .50-.80 Sulphur, .045 max. Phosphorus, .045 max. Chrome, .40-.70 Nickel, 1.00-1.50	Ultimate, 150,000 Yield, 130,000 Elongation, 14% Reduction area, 40% Gears Brinell, 325-365	Quench 1540-1560 in oil Draw 890-910 Draw gears 8000

Gasoline Vehicles for Explosives Transport

FOR some years before the war British Inspectors of Explosives had been pressed to obtain approval of the conveyance of explosives in gasoline motor vehicles, but in view of the number of fires occurring in connection with such vehicles they considered they would not be justified in accepting the risk involved. From the very outbreak of war, however, the employment of gasoline motor trucks became a matter of necessity, and it was therefore deemed desirable to legalize the position by obtaining the approval of the Secretary of State to the temporary use of these vehicles under certain specified conditions for the carriage of explosives during the war only. As a result, however, of the vast experience gained during the four years of war, the authorities recommended that this approval should be made permanent, subject to certain conditions. In October last these facilities were further extended by the approval of the conveyance in any mechanically driven vehicle of modern design of small-arm nitro-compound in quantities not exceeding 500 lb., provided all reasonable precautions are taken to prevent accident.

Trends Shown by Statistics of New York Show

These trends are, frankly, not representative of the industry. They are comparisons of the cars exhibited in the New York show. The list of exhibitors and the number of cars shown by each should be kept in mind. Perhaps the most interesting feature is the trend in number of cylinders.

DESPITE various differences in engineering and merchandising features, the outstanding statistical fact of the 1921 New York Show was its similarity to the 1920 exhibit.

Exactly the same number of exhibitors were represented, although the ratio between accessories and car exhibitors changed slightly. Of the 307 exhibitors in 1920, only 81 presented cars, while this year there were 86 different car exhibits. Seven more cars were shown than last year.

Three electric cars were represented by seven models, while one steam car was shown. One of the electric cars exhibited a stripped chassis.

The sharpest change in statistics is noted in the relative number of four-cylinder and six-cylinder models shown. In the four-cylinder models there was an increase of 15 over last year, while a decrease of 10 in the number of six-cylinder models appears.

These statistics are especially interesting, since an analysis of the figures for past years shows an almost continuous increase in the proportion of six-cylinder models shown each year since 1914 and an almost proportionate decrease in the four-cylinder type. The six-cylinder type comprises about 62 per cent of the total, however, and so must still be considered as the dominating model.

There were 31 eight-cylinder cars shown as against 29 last year, the change being so slight as to indicate merely that this type is holding its own. There were but three twelve-cylinder cars shown this year, all by the same exhibitor.

Only two exhibitors showed air-cooled cars, the total cars of this type being seven. There were 12 sleeve-valve motors, the other 321 being tappet valve types.

The L-head type of valve placement was numerically the largest with 180, being followed rather closely by the valve-in-head type with 119.

The four and five-passenger touring car was the most popular of the open models, while the increasing popularity of the sedan is indicated by the fact that 80 models of this kind were shown. Thus two-thirds of the closed models exhibited were of the sedan type.

Despite a goodly number of disk and wire wheels, artillery wheels, usually of wood, were used on 63 per cent of the cars exhibited.

Several features which appeared in past years were no longer found, even in small numbers at this year's show. The two-cylinder car, which appeared for a brief space in 1914, was missing, while the last motorcycle exhibit has apparently disappeared from the automobile show. In 1920 one motorcycle was shown, but this year no exhibit of this kind was to be found.

HOTEL EXHIBITORS 1921

Total exhibitors	13	2-3 passenger roadsters	3
Cars exhibited (all gasoline)	19	4-5 passenger touring cars	2
Stripped chassis exhibited	2	6-7 passenger touring cars	4
Four-cylinder	12	2-3 passenger coupes	2
Six-cylinder	4	4-5 passenger sedans	5
Eight-cylinder	3	6-7 passenger (other closed cars)	1
Air-cooled	1	Wire wheels	4
Water-cooled	18	Disk wheels	4
Tappet valve	18	Wooden wheels	11
Sleeve valve	1		

As usual a number of exhibits were shown in the hotels, but the statistics concerning these cars follow out very closely the general trends indicated by the figures on the show itself. There were 19 cars in the outside exhibits, 12 of which were four-cylinder jobs, 4 were six-cylinder, and 3 were eight-cylinder. The sedan dominated in the closed-body field of this group as well.

THE Index to Vol. XLIII of AUTOMOTIVE INDUSTRIES, covering the last half of 1920, is just off the press and will be forwarded without charge to subscribers who send their name and address with request for a copy. The index is mailed only to those who request a copy. Now is the time to ask for one if you wish it.

If You Are Planning to Sell Trucks to Corn Belt Farmers

Here, condensed for quick reading, is the experience of 831 farmer-truck owners in Mississippi Valley states. Their opinion of the trucks they now use should be well worth while to the sales manager who is planning a campaign for farm sales. Roads, after all, is the big question.

SUMMARIZING the experience of 831 corn-belt farmers who own motor trucks, the United States Department of Agriculture found that in the opinion of nine-tenths of these men, the greatest advantage in owning a motor truck is "Saving Time"; in the opinions of three-fourths of them the greatest disadvantage is "Poor Roads," and 91 per cent believe that their trucks will turn out to be a profitable investment.

The reports, however, indicate that on most of these farms the truck has not reduced expense to any great extent, and that it supplements rather than replaces work-stock and other equipment.

On the average these trucks travel 2777 miles per year and the cost of operation is between 16½ cents and 17 cents per mile, making the total annual cost from $460 to $470. Each truck displaces an average of 1.2 head of work-stock. With the cost of keeping a horse a year in the corn belt around $200, the reduction in expense for this item is in the neighborhood of $240 per farm. For all farms the average amount of hired help saved by the trucks is $163. On most farms these are the only two items of direct reduction in expense which can be credited to the truck, and on the average they amount to $60 or $70 less than the total cost of operating it.

To offset this added cost, custom hauling done with the trucks amounts to about $50 per year for all farms, leaving only something like $10 or $20 annual net expense, which must be more than balanced by the saving of time of the owner, and members of the family, the ability to get crops and livestock to market in better condition or at better time, and other benefits which are not directly measurable in dollars and cents, if the average truck is to be a profitable investment.

It must be remembered that most of these farms where trucks are owned are larger than the average, and are located at a considerable distance from market.

The investigation was made during the past winter and spring. Farmer-truck owners in Indiana, Illinois, Missouri, Iowa, southern Wisconsin, southern Minnesota, southeastern South Dakota, eastern Nebraska, and eastern Kansas, who raise corn as one of their principal crops, and who practice the general grain and live-stock farming characteristic of the corn belt, reported to the department the use they make of their trucks, the cost of operating them, the advantages and disadvantages of trucks for farm use, and other related information.

A study of the reports of 831 of these farmers has just been completed by the Division of Rural Engineering of the Bureau of Public Roads and the Office of Farm Management and Farm Economics.

Some of the important facts revealed by the investigation are:

The average size of the farms is 346 acres and their average distance from market is eight miles.

Only 14 per cent of them are less than five miles from market, and 20 per cent are 15 miles or more from market.

A little over one-fourth of these men have changed their markets, for at least a part of their produce, since purchasing trucks. For those who have changed market, the average distance to the old market was seven miles, and to the new market is eighteen miles.

The rated capacity of these trucks varies from one-half to two tons. Seventy per cent of them are rated at one ton, and only 9 per cent of them at less than one ton.

Experience with trucks has caused 57 per cent of these men to decide that the 1-ton size is best for their conditions, 25 per cent that the 1½-ton size is best, and 12 per cent that the 2-ton size is best. Practically one man in four has decided that a truck larger than the one he now owns would be better suited to his conditions.

Ninety-one per cent believe that their trucks will prove to be a profitable investment.

As compared with horses and wagons the trucks save about two-thirds of the time required for hauling to and from these farms.

On the average there are over eight weeks during the year when the roads are in such condition on account of mud, snow, etc., that these trucks cannot be used. The roads on which nearly 95 per cent of them usually travel are all or part dirt.

The condition of the roads prevented the use of the trucks with pneumatic tires a little less than seven weeks during the year covered by the reports, and of those with solid tires a little over nine weeks.

Twenty-four per cent of the trucks are equipped with pneumatic tires, 27 per cent with solid tires, and 49 per cent with pneumatics in front and solids in rear. However, experience has convinced 58 per cent that pneumatics are best for their conditions, 35 per cent that solids are best, and 7 per cent that pneumatics in front and solids in rear are best.

These men have return loads for their trucks about one-third of the time.

A majority of these men still use their horses for some hauling on the road.

On more than half of the farms all the hauling in the fields and around the buildings is still done with horses and wagons.

About 40 per cent of these men did some custom hauling with their trucks during the year covered by the reports. The average amount received by those who did such work was $132.

Their owners estimate that on the average these trucks travel 2777 miles and are used on 112 days per year.

The average estimated life of these trucks is six and one-half years, and on this basis depreciation is usually the largest single item of expense in conneciton with their operation.

The average cost of operation, including depreciation, interest on investment, repairs, registration and license fees, fuel, oil, and tires, is 15.2 cents per mile for the ½ and ¾-ton trucks, 15.2 for the 1-ton, 21.3 cents for the 1¼ and 1½-ton, and 25.8 cents for the 2-ton.

The average cost of hauling crops, including the value of the driver's time, is 50 cents per hour, is 24 cents per ton mile with the ½ and ¾-ton trucks, 24.1 cents with the 1-ton, 23.3 cents with the 1¼ and 1½-ton, and 21.5 cents with the 2-ton trucks.

Nearly 85 per cent of these trucks had not been out of commission when needed for a single day during the year covered by the reports, and 80 per cent of the owners stated that they had not lost any appreciable time on account of motor and tire trouble, breakage, etc., when using their trucks. About one truck in 15 was out of commission more than 5 days, however, and one owner in 40 reported a loss of more than 5 per cent of the time when using his truck.

Fifty-six per cent of these men have not reduced the number of their work-stock since purchasing trucks. Twenty-four per cent have disposed of one or two head, and 20 per cent of more than two head. The average reduction for all farms is 1.2 head.

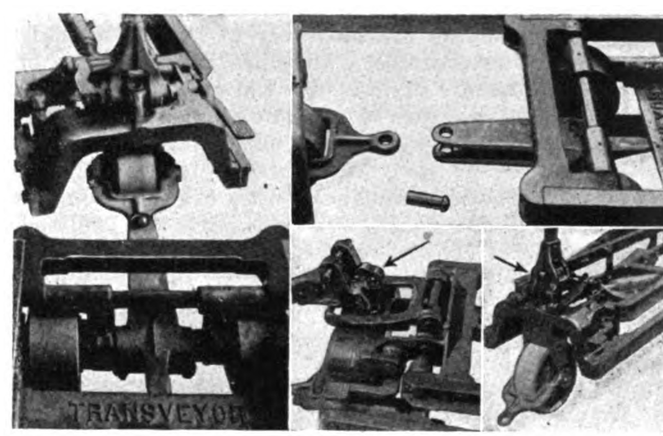
Half of these men own tractors as well as motor trucks. Most of the tractors are owned on the larger farms, however. **Only 33 per cent of the men whose farms contain 160 crop acres or less own tractors, while 65 per cent of those with over 320 crop acres own them.** The number of work stock kept on the farms where both trucks and tractors are owned is only slightly less than the number kept on the farms of corresponding size where only trucks are owned.

Seventy-eight per cent of these farmers state that their trucks reduce the expense for hired help. On those farms where there is a reduction, the operators estimate that it amounts to $209 per year on the average.

Transveyor Trailer Attachment and Safety Handle Latch

AN attachment recently developed for the Cowan Type G Transveyor enables the latter to be used as a trailer behind industrial trucks, either singly or as a train. The attachment fits on to the front wheel fork and hitches to the draw bar on the rear axle of the Transveyor ahead of it, or the draw bar of the electric truck. We are informed that with this attachment the trucks track quite closely and the turning radius is such that a train of ten can be turned in a 20-foot roadway. Plenty of up and down play is allowed, so that there will be no binding as the machines go over door sills or the top of steep inclines.

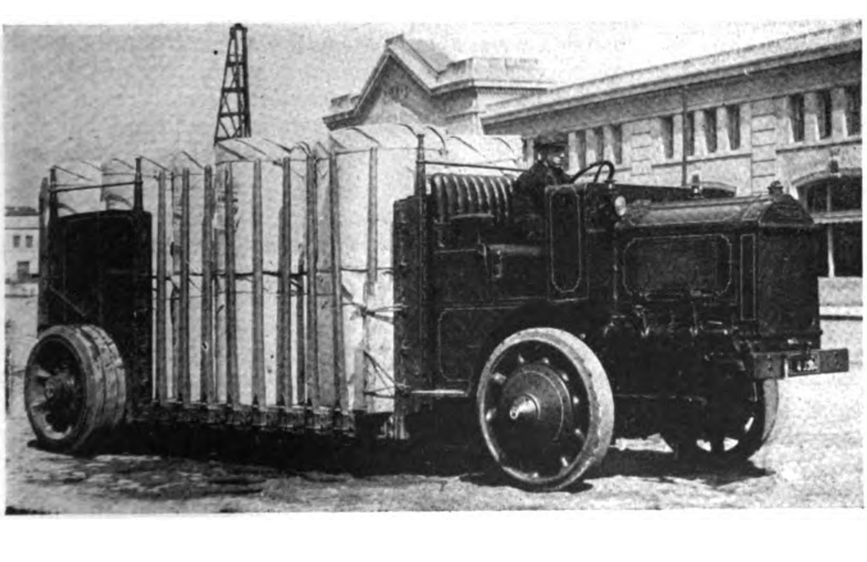
The safety handle latch, also illustrated, is the result of calls from safety engineers for a handle that will not fall down under any circumstances. The latch is made of tempered spring steel attached to the top of the king pin of the front wheel fork. It has two leaves.



Transveyor trailer attachment and safety handle latch

As the handle is thrown back into a vertical position, it slips over the spring, and jarring will not cause the handle to fall forward. The latch, however, does not interfere with the free movement of the handle, when it is necessary to bring it down to manipulate the Transveyor.

McDonald Front Drive Truck



A SPECIAL design of truck chassis, particularly adapted to low bed construction, has been developed by the McDonald Truck & Tractor Co. The drive is to the front wheels, through a chain and an internal gear. The main load frame is carried on three-point suspension, while the powerplant rests on a separate frame and spring. Steering is accomplished by the McDonald hydraulic steering gear, and the brakes are also hydraulically operated. All of the mechanical parts are located at the front end, which is referred to as the chassis, exclusive of the rear wheels, tires and bodies.

There is considerable latitude in the type of body which may be fitted to this truck chassis, but so far the company has been specializing on low bed trucks.

Protective Machinery in Danger of Becoming Cumbersome

As protective organizations are multiplied, or as machinery for the settlement of labor disputes is erected, the efficiency of our productive system decreases. In both business and political affairs, the smallest amount of system which will insure order is the most efficient.

By Harry Tipper

ONE of the things which we are apt to forget in the consideration of modern and social industrial affairs is the extension of the machinery for organization protection and legislation in all kinds of occupations and in all kinds of industrial groups.

Where such organizations perform a real service in increasing the understanding, improving the knowledge or otherwise developing the efficiency of the individual or concerns who are members, they are a part of the productive development of industry and can be accepted as valuable in the progress of the industrial world. Where, however, their primary purpose is to protect the members from outside aggression, from legislative difficulty or to protect their privileges, such organization adds nothing to the total productive capacity of the individual members and is concerned either with the retention of their profits, with the extension of their privileges or the maintenance of their position against other groups.

This, of course, includes to a very large extent the work of the operating parts of government. For while it is true that all these protective organizations, including the government bodies, are concerned with the improvement of knowledge in some of their endeavors, they are more largely concerned with protecting the social body at large or the industrial group from the aggressors who would destroy its peace and order.

Most of the members of these organizations have no concern either immediate or remote with the increase in the country's productivity, or the efficiency of the social organization. They do not add anything to the wealth, but instead reduce the wealth by the amount required to maintain them and to continue their operations. This does not mean that they are unnecessary. It simply means that they cannot be viewed as an advantage to the social or industrial organization, except as the organization requires protection against itself in its inability to co-operate peacefully and fairly in the work of improvement.

It means also that extensions of such organizations and particularly extension of government operations should be weighed very carefully as the continual development of the government expense is a continual additional drain upon the industrial capital, from which no corresponding return is received.

We are already burdened with a multiplicity of laws and with a wealth of technical detail in law which requires an enormous amount of information and still greater amount of advice and consideration in regard to its proper interpretation.

If the departments of government are multiplied and additional machinery provided with the idea of curing every economic ill from the labor trouble to the cost of raw product, new restrictions will be required and new departments for the enforcement and interpretation of those restrictions must be developed. This is just as true of the machinery of organization for the settlement of the labor problem.

Suggestions are made on all sides looking to the erection of national and State machinery for this purpose and the development of new tribunals before whom adjustments may be made. It is possible to carry this organization to such a degree that it becomes burdensome in the extreme without developing any hopeful basis for the solution of the problem.

Reference is frequently made to the machinery for the adjustment of labor problems in Great Britain, but this machinery has not lessened the demands or ended the warfare in industry in that country. On the contrary it has made the local settlement of a problem much more difficult; so that the ponderous machinery of the whole labor organization may be put to work all over the country for the settlement of a matter which was originally confined to a question of personal privilege in a single shop. It is not so long ago that the discharge of an employee on one of the railroads brought the country within a day of a complete railroad strike.

Unless this machinery of organization makes for enlightenment, for a better understanding between the individuals in each case, and for a better co-operation between the small groups, it is an addition to the governmental machinery which is not productive, which does not increase the wealth and which on the other hand withdraws some of the labor from productivity for the maintenance of its own organization.

Carlyle once called attention to the ability of the Anglo-Saxon to get along with a small amount of government as one of the strong features of the racial development. At all times the minimum amount of government required to maintain order is the maximum amount of efficient government.

The tendency to centralize organization authority both in political and industrial matters enlarges the governmental operation in both cases without materially enlarging the usefulness and efficiency of the result.

It is still true that if you have co-operation and order in each community in a state, it will not be difficult to

secure order throughout the state. It is still true that if there is co-operation and decent measure of justice between each employer and his employees there would be no general problem of industrial unrest.

Government is necessary so that chaos may be avoided and the industrial and social organizations continue to function, but there is a tendency to burden the government of the country and the state on political matters, the group governments of industry on industrial matters, with innumerable operating questions and innumerable precedents, traditions and restrictions. These are supposed to take the place of the co-operation between the individuals in the small group, the industrial or social unit and force improvement from the general to the individual. All this machinery is very expensive and it will not do the work which it is supposed to do, because the improvement grows from the individual to the small group and from the small group to the larger group.

This type of organization is expensive because it removes from productive work the man power which is required to maintain it and the capital which is required to pay for that man power.

In one of the articles a week or so ago, we stated that system was of no value unless the spirit of improvement and adjustment were there, and the spirit of improvement begins with the individual, with the understanding between individuals and adjustment of their relations by virtue of their understanding.

Whether in business or in political affairs, the smallest amount of government system which will insure order is the most efficient amount because it removes from the production of necessary commodities only those men who are absolutely essential for the maintenance of the order and the establishment of improvement in the spread of knowledge, the spread of understanding and the development of justice.

There is a tendency for all organizations of this type, whether they are concerned with politics or industry, to enlarge their own operations, to feed upon themselves, and this tendency is sharply indicated by the developments which have taken place in the last year and the developments which are foreshadowed in recent demands for future organization in politics and business.

If half the money were spent upon the education of the young citizens which is spent on the extension of restrictions for the adult, the necessity for those restrictions would be materially lessened and the money which had been expended would have been productive of a better type of citizenship and a more efficient organization. If half the money spent by industrial organizations, whether labor, professional or capital, were expended upon providing a better basis of understanding, a better common ground of knowledge and a visible area of fair play, the necessity for such protective work would be materially decreased and the efficiency of the industrial machine notably strengthened.

At this time when there are so many patent medicine venders, each with a system of restriction which is calculated to organize the nation into the millennium both industrially and politically, it is well to scrutinize with very great care every proposed extension of organization activity and see whether it is founded upon the positive platform of education, improvement and understanding in the development of justice, or whether it is formed on the negative platform of protection of privilege and rights, maintenance against aggression, and so forth.

Furthermore, all these proposed extensions of present systems or developments of new systems should be subjected to the acid test—how they will affect John Smith who is working for you and your managers, or how they will affect your neighbors and the other citizens of your community.

Unless they are inclined to bring a better element of understanding into your organization between the management and the men and between the owners and the management, they are of little use industrially and will simply add a burden to that which we already carry. Unless they are inclined to increase the understanding between the members of your community and to develop order in that community, they are of little use politically and will simply add a new burden for which industry must pay.

This does not mean that either the private citizen or the industrial owner should be allowed to retain his privileges if they are not consistent with the general good, but it does mean that a lot of the systems suggested and the additional operations talked about are suggested and talked about in the hope that they will take the place of better education and better understanding—in the hope that they will cure our troubles without labor and without thought, by some magic in the systems themselves.

Placing Responsibility in Kansas

ONE point in a recent decision of the Kansas Court of Industrial Relations is of particular interest from the employers' point of view. The law under which the court operates, it will be recalled, provides not only that strikes may not occur in certain basic industries, but that manufacturers may not arbitrarily cease operations at their own discretion. Recently a complaint was brought by employees against the Topeka Flour Mills, which not long ago closed down to about half of its capacity. A part of the Court's decision was as follows:

"The people of Kansas have solemnly declared by legislative act that workers engaged in this industry shall at all times receive a fair wage and have healthful and moral surroundings. In the reduction of hours of operation, therefore, the millers should be very careful and solicitous concerning the matter of labor.

"Skilled and faithful employees should be given such treatment as will enable them during the period of limited production to support themselves and their families."

Such a statement would seem to imply that with industry organized on a capitalistic basis, the responsibility of providing at all times an opportunity to gain a fair living wage to those who are willing to work rests upon the employer. A discussion of this decision is expected to develop some interesting opinions and information.

DURING the year 1919 there were in Great Britain 747 trade disputes resulting either in a strike or a lockout. During the first six months of 1920 there were 1,004 such disputes, or 34 per cent more for six months than in the whole preceding year.

The number of persons involved in the 1919 disputes, however, was 1,434,000 as against only 592,000 in the first half of 1920. This would indicate that although the 1920 troubles were more numerous, their importance was less in the average case.

The S. A. E. Meeting

THE plan of holding simultaneous sessions on diversified subjects at the annual S. A. E. meeting proved highly successful and will no doubt be followed at future meetings of the Society. The only reason for not following this practice heretofore has been the belief that the attendance at one or more of the sessions held at the same time would be too small to make the practice worth while. Quite the contrary has turned out to be the case. All the sessions were well attended and at all of them the attendance was larger than was that at some of the sessions of the annual meeting of the American Society of Mechanical Engineers, a much older organization with about double the membership of the S. A. E.

There is still much room for improvement in the actual presentation of the papers, particularly those which are in type at the time of the meeting. Announcements of the meeting stated that authors would give short, crisp digests of their papers without boring the audience with details contained in the printed manuscript which all can read at leisure. This was done in some few cases, but in others quite the reverse was true. Another mistake, which should be avoided in future, is that of having several papers presented without pause for discussion and then allowing all the discussion to come at the end. By so doing many important points which should be brought out in the discussion are lost and the author's summary in reply is frequently not given at all.

The life of a meeting is usually in the discussion, providing the chairman is, as he invariably should be, familiar with the subject. The chairman should be selected well in advance of the meeting, should be furnished with copies of all papers to be read at his session, and should have before him a list of men specially qualified to discuss the subjects in hand. These men should all receive copies of the manuscripts in advance so that their discussion will be well thought out and to the point. Whenever possible all members should receive preprints of papers with request that they forward written discussion if they cannot be present at the meeting.

When simultaneous sessions are held there should be ample time for discussion, and the chairman who knows and performs his job will see that this discussion is brought out even at the expense of missing some of the papers scheduled. It is, of course, unfortunate to disappoint an author who has spent much time in preparing a paper, but it is worse to throttle discussion which is pertinent and timely, even though this may cause criticism on the part of the author whose paper is not read. Reading a paper before an organization of such standing as the S. A. E. should be regarded as a privilege; that is the Society does the author an honor by asking him to speak on a subject—the author does not confer a favor by consenting to speak. Consequently if a given subject excites unusual interest the chairman must think of the greatest good to the greaest number and perhaps forego the reading of one paper in order that another which seems to attract much interest may be fully discussed.

Correct Registration Figures

THE registration of motor cars and trucks in the United States for the year ending Dec. 31, 1920, was announced in these columns last week as 8,873,-572. This figure was a surprise to even the most optimistic. We believe that it is as accurate as was possible under the circumstances, meaning the haste in which the figures were gathered.

The difficulties of gathering registration statistics are not generally understood and frequently some one undertakes this task without a full knowledge of it. State governmental departments are often cumbersome. There is a fixed way of doing things and these methods are not responsive to an effort to gather figures promptly. Then, too, each state has peculiarities of registration. It is a considerable task to learn in just what states the total figure given out includes re-registrations, trailers and the tractors used for industrial purposes, etc. In some cases dealer licenses are subtracted from the total. Other states do not follow this practice.

The figures we published represent an intelligent handling of the figures supplied by the State officials. In some cases these officials have asked the privilege of revision. The revised figures will be printed in the Statistical Number of AUTOMOTIVE INDUSTRIES on Feb. 17. Several of these revisions have been received since the publication of the table in our issue of Jan. 13. So far the revisions have not changed the State totals to any material extent.

While on this topic it should be said that if the registration figures are to be made of the greatest benefit to the industry, many State laws must be revised. This is merely another argument in favor of adopting the proposed Uniform Vehicle Law.

Effect of Weight on Fuel Consumption

THE subject of fuel economy is attracting so much attention to-day that makers of parts and fittings for automobiles generally are considering to what extent their products contribute to this factor. In this connection the question has come up as to how the weight of an automobile and its fuel consumption are related, and some experimental results have been quoted to us which make it appear that the consumption decreases, not in proportion to weight reduction, but much more rapidly. For example, a reduction in weight of 10 per cent is said to have resulted in a reduction in fuel consumption of over 20 per cent. This, however, is absolutely contrary to all previous experience. The resistance to the motion of an automobile on level road is made up of two factors, namely, road resistance and air resistance. The first is generally taken as directly proportional to weight being moved, and this assumption is in accordance with all physical laws and also with observations in tests. According to this law it requires at low speed exactly twice the force to move a loaded truck weighing six tons, as to move the empty truck weighing three tons.

At higher speeds account must be taken of the air resistance, and at 25 m.p.h., which is perhaps a good average driving speed, this resistance becomes an important item. The air resistance is entirely independent of the weight to be moved and varies only with the projected area and the form of the body and other exposed parts. It will readily be realized that even at a fixed speed the relation between the power necessary to overcome road resistance and that required to overcome air resistance varies widely, because of the different shapes which can be given the vehicle body. A car with a large windshield perpendicular to the axis of a car would evidently encounter much more resistance than one without windshield and modeled in true streamline form. For a touring car of average weight and dimensions the air resistance at 25 m.p.h. is about one-half the road resistance. The air resistance, of course, remains constant for a car of given dimensions even though, through the use of higher grade material, etc., the weight of the car be reduced. For instance, if the weight is reduced, say 10 per cent, the road resistance will be reduced in the same proportion, and the combined air and road resistance at a speed of about 25 m.p.h. would be reduced from 150 per cent to 140 per cent of the original road resistance. In other words, a 10 per cent reduction in weight at the speed mentioned should result in a fuel saving of 6 2/3 per cent. The saving would approach 10 per cent at very low speed and would practically vanish at very high speed.

The lighter the car the less fuel will be required for acceleration and for hill climbing, but here again the gain is substantially in proportion to the difference in weight, so long as the engine remains the same size.

The above is not intended to discourage designers who are striving to cut down the weight of their cars. Reduction of weight does result in economy, especially at low speeds at which the reduction in fuel consumption is substantially in proportion to the saving in weight. The chief reason why the light car consumes less fuel than the heavy car is due to the fact that a smaller engine can be used.

Just Taxation

THE question of federal taxation was one of the most discussed topics during the gathering of the motor vehicle manufacturers last week and the general attitude of the manufacturers was one that cannot but meet with the approval of all fair-minded people. The manufacturers frankly believe that if the recommendations in the annual report of Secretary of the Treasury Houston are made effective, their industry will be discriminated against. They believe that an industry which produces anything so thoroughly a utility as the motor vehicle should not pay a heavy burden of taxes. Indeed, a suggestion made early in the week that the automotive industry offer to pay taxes comparable with those imposed upon railroad locomotives and equipment was often quoted.

There is no spirit of evasion of a just share of taxes. The automotive manufacturers realize that this country is heavily in debt and that this debt must be paid. They are just as patriotic to-day as they were during the war. It is the apparent disposition in some quarters to class their products as non-essential that annoys them more than the amount of money involved. Then, too, the manufacturers believe that just as they are striving to reduce the fixed charges in their business, so the government should make every effort to reduce its fixed expenses and put into effect the most modern business methods for the saving of money compatible with efficiency.

The Tax Committee of the National Automobile Chamber of Commerce is considering the problems before it. Circumstances make this one of the most important committees of the national body. From all appearances this committee is setting out to do a constructive work. When its representatives appear before the Congressional Committee they will have something to say besides entering a protest against taxes, as recommended, and will endeavor to assist the representatives of the government in reaching a just solution of the problems.

Durant Picks Flint for New Plant

First Unit Slated for Old Home Town

Hohensee and Sturt, Chevrolet Officials, Join Former Chief—Organization in Process

NEW YORK, Jan. 18—The first unit of Durant Motors, Inc., incorporated at Albany late last week by William C. Durant, former president of the General Motors Corp., will be located in Flint, Mich. This decision was communicated to-day to the Flint Chamber of Commerce and was in compliance with earnest appeals to Durant to return to the city where he gained his first fame and which he is credited with having "put on the map."

News that Durant was going back into the automobile manufacturing field with a car of his own has created intense interest throughout the industry, but it caused a sensation in Flint, and ever since it was made his temporary offices in the Goodrich Rubber Co. building have been deluged with telegrams of congratulation and best wishes. They also have brought more substantial wishes, including an offer of a free site of 40 acres of land for a plant.

Durant has not told his plans in detail and probably won't for a month yet, but he already is rounding up an organization. The first man to join him was F. W. Hohensee, who resigned as a vice-president, director and member of the finance committee of General Motors the same day last week that Durant retired as a member of the finance committee and chairman of the executive committee. Hohensee has been known as one of the most capable men in General Motors, where he has been general manager of production for the Chevrolet company.

Durant to Design New Car

The second man to go with Durant was A. T. Sturt, chief engineer of the Chevrolet company. He has had much to do with the development of that car. The fact that these two Chevrolet executives have joined Durant adds significance to his announcement that Durant Motors would produce a 4-cylinder car which would sell for less than $1,000. It is understood, however, that the new car will include several features Durant has had in the back of his head.

It is probable it will be in a little higher price class than the Chevrolet, but will lend itself to quantity production. When it will be placed on the market has not been determined, but it is expected the company will be in operation by Aug. 1. In addition to the Flint plant another factory will be located in the East, and it is possible the company will have a separate unit for the manufacture of engines and other parts.

The authorized stock of the company will be $5,000,000, consisting of 1,000,000 shares of no par value. All the stock will be taken by Durant and close personal friends. It is significant that the day after the incorporation papers were filed there was active trading in the stock on the curb market on a "when issued" basis. It was the understanding that the stock was offered for subscription at $10 a share, but most of the trading was at between $13 and $14, and the turn-over approximated 3000 shares.

Durant made the following statement:

Friends and Self to Control

"While I am not ready at this time to make an announcement, it will probably not surprise you to know that I am still an interested and firm believer in the motor industry, and that I am organizing a company controlled by myself and several of my good friends, which will be in active operation Aug. 1. I cannot go into details regarding the corporation at this time other than to say it will bear the name of the Durant Motors, Inc., with one kind of stock, with no commissions, bonuses or reservations to myself or associates issued for experience, ability or performance. The Durant Motors, Inc., will be incorporated under the laws of the State of New York with authorized capital of 1,000,000 shares of no par value, 500,000 shares constituting the initial offering."

No further statement has been made as to the financing details or the names of Durant's associates. The three incorporators, besides himself, were office employees. When the company is finally organized the names of three or four men of country-wide reputation will appear on the directorate.

Decision to locate the first plant of the company in Flint was due partly to sentiment. Durant won his first success in that city and it always has been loyal to him. Immediately after he was forced out of General Motors the directors of the Flint Chamber of Commerce adopted resolutions which expressed "in behalf of the citizens of Flint the deep appreciation of his services to this community," and voiced "the hope that when his responsibilities permit he again will take up is residence here among the friends who love and respect him."

Replying, Durant said:

"You may say to the good people of the best little city in this country that one of the plants of Durant Motors will be located in Flint and say to those who so thoughtfully remembered me that I am most appreciative of and quite overcome by their kind messages of friendship, confidence and affection."

Show Sales Rate Up With Normal Years

Executives Regard New York Results as Auspicious—Credit Conditions Harmful

NEW YORK, Jan. 17—A final canvass of the New York show reveals these facts: Attendance compared favorably with last year and was generally accepted as better in "quality," a conclusion supported by the reports of exhibitors that "live" prospect lists obtained are far larger than those of 1920; retail sales on the floor aggregated between 50 and 75 per cent of the record of last year and were fairly well up to results of previous New York shows, except that of 1919 conducted by the metropolitan dealers and making the first public showing of automobiles after the armistice.

Show sales of cars in the class above $3,000 ran about 50 per cent of last year's, in the $1,500 to $3,000 class about 75 per cent and in the class below $1,500 a little less than 75 per cent. Some exhibitors made no sales, others did only 5 to 10 per cent of last year's business and four or five sold more cars than they did in 1920, but the average held pretty well between 50 and 75 per cent.

Wholesale business continued right up to the end of the show and was such as to give factory executives encouragement to prepare for a fair and steadily growing volume of late winter and early spring business. Dealers reported very little improvement in the stringent situation as regards financing of time sales and said bankers had not shown much inclination yet to extend additional credit for financing wholesale purchases. For this reason dealers in a good many cases placed orders for cars in small lots but expected to make almost immediate sales to finance further orders.

New York and suburban dealers expect to keep up a growing volume of sales as a result of the fine prospect lists obtained and factory executives are counting on similar aftermaths of succeeding shows to improve the situation throughout the country.

Attendance Within 10 Per Cent

Final attendance figures showed the crowds within 10 per cent of last year's except on the opening Saturday and Friday, when the attendance was poor. Friday there was rain, at times approaching the intensity of a cloudburst, practically all day. On Thursday the attendance was within 500 of the record of the New York shows. The aggregate attendance was well up toward the average of all previous years except the one held in 1920.

Many Companies Seek New Finances

Banks Aid Industry in Arranging Loans

Co-operative Spirit Helpful in Meeting New Money Strain—Credits Extended

NEW YORK, Jan. 17—Notwithstanding the easing of credit and the improvement in the general situation, the next few weeks are likely to prove the most critical encountered by manufacturers in the automotive industry since the post-war readjustment began. This is due to the fact that nearly all companies have had coming due since the first of the year large bank loans and bills to merchandise creditors.

Most companies are short of cash and as a consequence more than one large corporation has found it necessary to ask its creditors for an extension of time. This condition is almost universal and is not by any means confined to the automotive industry. As a matter of fact some other lines are in much worse plight.

Banks generally have assumed a constructive attitude and are willing to do anything within reason to keep the companies to which they have made loans moving along as going concerns rather than take action which might precipitate receiverships with a consequent shrinkage in assets. It is realized that few companies are in a position to pay all their obligations at this time.

A similar stand is taken in most cases by large merchandise creditors. They feel that if receiverships and involuntary bankruptcy petitions are avoided, they will be infinitely better off than they would be if the affairs of their creditors were placed under the direction of the courts. This means that appeals for extension of time on loans and bills are being received with sympathetic interest. In almost every case where it can be shown that the companies would be solvent under normal conditions—and there are innumerable cases of this kind—the accommodation asked is being granted.

No Stigma to Cash Shortage

Manufacturers and banks are a unit in feeling that no stigma attaches at this time to requests for extension of time. Almost everyone is in the same boat. For that reason, less significance than usual should be attached to meetings of creditors. In most cases they are being called by the companies themselves for the protection of creditors and in the hope that some amicable plan can be agreed upon to carry them through the crisis.

A great deal of refinancing is being engineered at this time although the negotiations have been completed in only a few cases. This applies to some of the largest companies in the industry. Important announcements along this line may be expected in the near future.

Banks have become more deeply interested in the automotive industry than they ever were before and they are convinced that its future is thoroughly sound. That is one of the reasons why they are perfectly willing to finance any sound company to which they already have made loans. They believe that by extending further help at this time, they can avert impairment of their investments.

If the next few weeks can be weathered safely, there is no need to fear serious casualties in the industry. Present conditions, however, make it even more dangerous than usual to rock the boat and invest with unusually sinister possibilities the circulation of reports that this or that company is in a bad way financially.

Implement Association Urges Standardization

ST. LOUIS, Jan. 15—More than 450 members of the Mississippi Valley Implement Dealers Association attended the fourteenth annual convention of the organization at the Planters Hotel in St. Louis, Jan. 11, 12 and 13. The annual election of officers resulted in the naming of Frederick P. Watson of Mt. Vernon, Ill., as president for the 1921 term. The name of the organization was changed to that of the Mississippi Valley Implement Vehicle and Hardware Association and the constitution and by-laws were amended so as to permit the inclusion in membership of dealers who retailed one or more of the lines.

According to the retiring presiding officer, Henry F. Woerther of Baldwin, Mo., the most important problems of the past year which promise to affect matters of the immediate future are power farming, elimination of deposits on tractor contracts, standardization of many vital spare parts common to similar implements and vehicles of various manufacture, one line contracts of motor and other vehicles, increased freight rates, C. O. D. shipments of repairs, well defined and exclusive territories and closer mutual understanding with heads of various farm bureaus.

COMET RESUMES PRODUCTION

DECATUR, ILL., Jan. 17—The Comet Automobile Co. re-opened this week with a small force of men. George W. Jagers, president, who has returned from a tour of leading Middle West dealers, said big distributers seemed more pessimistic over the future than the smaller ones, but general conditions warranted beginning of operations.

Treasury Revises Excise Tax Clauses

Top and Body Rebuilders Defined Manufacturers—New Adjustments Now Permitted

WASHINGTON, Jan. 17—Revision of tax regulations as announced here to-day by the Treasury Department imposes excise taxes on garagemen and others engaged in extensive repairs to automobile tops or bodies. The ruling places "a person, partnership or corporation engaged in business of building over automobile tops or bodies for installation on new or old chassis as manufacturers of automobile parts or accessories and subject to such a tax."

Furthermore, the Treasury has revised Regulations 47 relating to excise tax on sales by manufacturers which affect the industry. As to the basis of tax, there has been a simplification in accordance with rulings in force. Certain examples have been added outlining the method to be pursued by a manufacturer in quoting and billing the tax in order to arrive at a basis of tax and to reimburse himself for the tax which he pays.

The theory is that if a manufacturer quotes the selling price of the article and the tax in separate and distinct amounts or quotes a flat price with the statement that a certain proportion of the quotation represents selling price and a certain proportion tax, the tax attaches only to that portion representing the actual selling price of the goods.

The ruling in Regulations 47 permitting an adjustment of the tax in the case of an adjustment in price on goods sold over a period of time on a quantity rebate has been extended to permit an adjustment in the tax in the case of an adjustment in price under an agreement made at the time of the sale to make such adjustment in case of a decline in the market.

New Ruling on Manufacturer

Article seven defines a manufacturer. This article has been modified to provide that while a manufacturer is generally a person who (1) actually makes a taxable article, or (2) by changes in the form of an article produces a taxable article, or (3) by the combination of two or more articles produces a taxable article, that under certain circumstances such a person is not a manufacturer for the purpose of the tax; but that if a dealer or jobber owns a patent, trade-mark, formula or recipe for a taxable article and contracts with another person or firm for the manufacture thereof, the contract specifying that the article

Nash Earnings Total $7,007,471 for Year

Company with $12,409,378 Cash in Unusually Strong Position —Sees Normal Year

NEW YORK, Jan. 17—A dividend of $10 a share on the common stock payable Feb. 1 has been declared by the Nash Motors Co. A regular quarterly dividend of $1.75 on the preferred also has been declared payable on the same date.

The annual report of the Nash Motors Co. for the year ending Nov. 30 shows a net income after Federal taxes of $7,007,471 equivalent after preferred dividends to $122.79 earned on the 54,500 shares of common stock of no par value. This compares with net income of $5,089,035 or $95.06 on the 50,000 shares outstanding in the preceding year. The profit and loss surplus at the end of the year was $12,531,837, an increase of $5,820,471 in twelve months. With $12,409,378 in cash, the company is in a tremendously strong position. The balance sheet as of Nov. 30 shows as follows:

Assets: Real estate, plant and equipment, $5,257,761; miscellaneous investments, $1,453,555; Liberty Bonds, $1,307,600; material and supplies, $6,212,163; notes receivable, $941,000; accounts receivable, $1,757,783; cash $12,409,378; prepaid expenses $20,023; total $29,359,263.

Liabilities: Preferred stock, $4,500,000; common stock (54,500 shares, no par value), $500,000; accounts payable $1,074,230, reserve for state and federal taxes, $7,468,858, other reserves, $3,284,337; surplus, $12,531,838; total $29,359,263.

In a letter to stockholders, President C. W. Nash said that sales for the year amounted to more than $57,000,000 or nearly $10,000,000 more than the preceding year. The company produced 37,263 passenger cars and 3,848 trucks. Its exports, not including those to Canada and Mexico totaled 2,700 cars and trucks. In his letter Nash said:

Milwaukee Plant Operating

"The first units of the new plant at Milwaukee are now completed and operations started. The new four-cylinder car being turned out there is meeting with a fine reception and it is expected that it will prove a great asset to the Nash motors line.

"We have put $1,573,083 into the Milwaukee plant for land, buildings, machinery and equipment, besides $1,280,709 for working capital. We also expended during the year $1,051,445 in the enlargement of the Kenosha six-cylinder passenger car and truck plant. We have practically no uncompleted construction on hand at present.

"For the first nine months of the fiscal year we were unable to keep up with the demand for our car, but beginning Oct. 1 we experienced a sharp drop which caused us to shut down our plant for a number of weeks and for the balance of the period up the present time to operate on a reduced schedule. We were expecting this reduction and when it came had on hand less than half a day's production.

"We intend to continue a conservative production policy because we regard our distributing machinery as the most vital part of our business and we also fully realize that the bankers who are co-operating with our dealers are just as much a component part of our organization as the dealers themselves.

"We are looking forward to at least a moderately successful year."

G. M. C. Consolidations Regarded Improbable

NEW YORK, Jan. 17—The General Motors Corp. closed 1920 in a strong position with its inventories of unfinished materials substantially reduced, its finances in good condition and comparatively few unsold vehicles on hand. It can be said with authority that the corporation does not contemplate any material expansion during the coming year, notwithstanding many reports now in circulation of consolidations with other companies.

It is felt the company's factories now are adequate to meet the demand for some time to come and that nothing will be gained by taking on additional lines. Efforts will be centered upon making all the various divisions as profitable as Chevrolet, Buick and Cadillac have been. There is a possibility that the company may abandon some of its activities not related to the automotive industry. It is understood the directors are not enthusiastic about retaining the big new Durant building in Detroit and they probably would not hesitate to sell it if an opportunity offered.

Cotta Offers Settlement at 25 Cents on Dollar

ROCKFORD, ILL., Jan. 17—Creditors of the Cotta Transmission Co., now in bankruptcy, have received a proposition from a syndicate composed of Rockford business men, to settle all claims upon the basis of 25 cents upon the dollar and the offer has been taken under advisement. The plant is also under consideration by a Chicago firm which proposes to utilize it for the manufacture of a new type of kerosene motor for tractors. If the creditors decide to accept the offer, it is likely that a deal will be arranged with the Chicago concern and the plant reopened for the manufacture of both engines and transmissions.

ROTH DENIES EMBEZZLEMENT

SANDUSKY, OHIO, Jan. 17—C. H. Roth, former secretary of the Erie Tire & Rubber Co., indicted on charges of embezzlement, has retained attorneys and proposes to fight the case to the end. He pleaded not guilty when arrainged and is now at liberty under bonds of $40,000. P. F. Wills, president of the company, has also been indicted.

Bankers Take Over Control of McGraw

Losses Due to Recent Market Conditions Cause Action—Choose New Directors

CLEVELAND, Jan. 17—The Maynard H. Murch Co., investment bankers of this city, has taken control of the McGraw Tire & Rubber Co. to protect the holders of preferred stock of the company. This action was taken pursuant to a right reserved when the Murch company bought a $2,500,000 preferred stock issue of the company in August, 1919.

At the offices of Mr. Murch it was stated that the rubber company suffered severe losses from two sources as follows: First, in operation through the reduction in tire prices that followed a slump in buying; second, through the shrinkage in value in the readjustment period of quantities of fabric and crude rubber, which were bought in too large quantities on a peak market. The Murch company on taking hold of the company directed that the inventory be written down to the present market prices for all assets on hand and that all losses through contracts that the rubber company had with firms throughout the country be charged off.

In making these reductions the McGraw Tire & Rubber Co. took a loss of $2,500,000. Most of the loss came about through marking down to present prices the fabric and crude rubber that had been bought when the market was soaring. A statement prepared by accountants showed that after taking the drastic action ordered by the Murch company, the rubber corporation had $2,800,000 of quick assets to its credit, while the debts amount to $1,700,000. In addition there is a plant account of $1,500,000.

Management Unsatisfactory

The Murch company, as guarantor of the preferred stock, has not been satisfied with the management of the company for some time, and it took the action indicated in order not only to protect the preferred stockholders, but to prevent affairs getting into a worse condition. Eight of the eleven directors of the company now are men selected by the Murch company. They are Maynard H. Murch, president of the Murch company; Walter S. Quinlan, vice-president of the Murch company; George E. Randall, president of the Foote-Burt company; William H. Marlatt, Cleveland lawyer; R. V. Mitchell, of the United Securities Co., Canton; A. H. Coffin of Counselman & Co., Chicago investment bankers; M. S. Bethel, of the Murch company, and Martin Gillan of New York, who represents New York City interests.

John Morgan was elected president of the rubber company; Quinlan, vice-president; Marlatt, secretary and treasurer. The chairman of the Board of Directors will be elected within three weeks and within the next month other announcements will be made about the personnel

Highest Court Holds Seizures Authorized

Innocence of Owners Not Involved in Volstead Violations —Can Extend Ruling

WASHINGTON, Jan. 17—Seizures of automobiles or any conveyances in which liquors are being carried contrary to law, were held authorized by the Supreme Court here to-day whether or not the owner of the conveyance has been found innocent of contravening the law.

The decision was rendered in an appeal from a Georgia court decision. An automobile loaned by J. W. Goldsmith to a friend was seized by Federal officers when found carrying intoxicants. The court held that when he entrusted his property to another he assumed the risk of loss from whatever cause it might occur.

Justice McKenna, who read the opinion of the court, went back to the Mosaic statutes for initial justification of the Government's contention, quoting from the ancient tablets that "if an ox gore a man that he die, the ox shall be stoned and his flesh not eaten."

Counsel for Goldsmith had contended that affirmation of the decision of the lower court might mean that a Pullman sleeper might be seized if a passenger carried a quart of liquor on board, or an ocean liner forfeited to the Government, if, unknown to those in charge, a case of liquor was transported in the hold.

"Whether these indicated possibilities under the law are justified, we are not called upon to consider," Justice McKenna said. "And we also reserve opinion as to whether the section can be extended to property stolen or otherwise taken from an owner without his consent."

Excessive Insurance Hurts Foreign Trade

NEW YORK, Jan. 18—The Foreign Trade Committee of the National Automobile Chamber of Commerce, has received complaints from members that marine underwriters had increased in some cases 200 to 300 per cent rates on so-called floater policies covering shipments from factory to foreign destination. The only explanation is that losses have been incurred, pointing particularly to damage by exceptionally long exposure to the weather during the freight congestion on the railroads in the past year or two.

Manufacturers feel that this risk is quite eliminated now that normal movement of freight may be expected. It was pointed out also that the underwriters distinguish only between the type of ship and the destination in fixing their rates, giving no consideration, however, to the highly important feature of boxing. Manufacturers who have developed and use a good strong package feel that they are being penalized on this insurance matter for damages occurring on inferior packages.

Many suggestions were made looking for relief from the increased insurance rates, among them the possibility of co-operative or mutual insurance among automobile manufacturers, whose foreign shipments of cars and trucks last year totalled $200,000,000. It was felt that the higher rates are particularly unfortunate at this time when foreign exchange and other conditions are tending to restrict rather than assist exports.

This whole question, together with prevailing practices of booking and forwarding shipments was referred to a sub-committee for further investigation.

Cab Company to Make New Ambassador Car

CHICAGO, Jan. 15—Passenger cars and light trucks will be manufactured in quantities immediately by the Yellow Cab Manufacturing Co. of this city, according to an announcement of the president, John Hertz. The company foi several years has concentrated its efforts on turning out 2000 cabs yearly for use in taxicab service in this and other cities.

One of the passenger cars will be known as the "Ambassador" and will be built in touring, closed, sports and imperial sedan models of 2, 4 and 7-passenger sizes. Greater production, however, will be on a 4-cylinder car, of moderate price, worked out on the "Yellow Cab" chassis. This line will consist of a 4-passenger coupe, sedan, touring car and roadster.

The trucks will include a 1-ton speed wagon and a 1¼ ton speed truck.

The cars will be exhibited at the Chicago automobile show for the first time. The "Ambassador" will be on display at the New Drake Hotel and at the show rooms of the distributers, Esch and Hammond, this city.

Manufacture of the cars and trucks will be made in the new factory of the company at Menard and Dickens streets and will mean an investment of several million dollars, according to Hertz.

COST ASSOCIATION TO MEET

NEW YORK, Jan. 17—The Industrial Cost Association whose principal office is in Pittsburgh, will hold a meeting in the rooms of the American Society of Mechanical Engineers, 29 West Thirty-ninth Street at 8 P.M., Jan. 20, to organize a New York section. Several of the national officers and directors of the Association will be present to tell of this movement. Judge Gary of the U. S. Steel Corp. has been asked to speak.

2000 SHERIDANS ORDERED

NEW YORK, Jan. 17—D. A. Burke, president of the Sheridan Motor Car Co., a subsidiary of General Motors, announces that dealer connections have been established in the principal cities from coast to coast and that dealers already have filed orders for more than 2000 cars. The 8-cylinder job probably will get on the market this month.

Hartford to Sue on Starter Patents

Car Manufacturers and Starter Makers Believed Liable by Counsel—Test Suit Ready

NEW YORK, Jan. 18—The possibility of a long list of suits against manufacturers of motor vehicles equipped with self-starters, and self-starter manufacturers for infringement of patent rights, has been opened with the award of four patents for self-starting systems to E. V. Hartford, president of E. V. Hartford, Inc., manufacturer of equipment, with a plant in Jersey City. A test suit will be started this week against a manufacturer of a standard automobile by Dunn, Goodlett, Massie & Scott, counsel for the patentee. Both the name of the manufacturer and the place of suit were withheld for the time being.

In the belief of counsel, every two unit system now on the market and in use in automobiles is an infringement on the Hartford patents in some particular. Notice of the Hartford award has been mailed this week to 230 car manufacturers throughout the country, as well as to every firm making self-starting systems.

According to counsel, the four Hartford patents as granted by the United States Patent Office on Jan. 4, this year, cover sixty-seven claims. In almost every instance these are on two-unit systems, though one or two claims are on one-unit. Applications for the patents were filed by Hartford at different times between the years 1910 to 1913. Reasons for delay in granting the patents are ascribed by counsel to the constant litigation instituted by others who had worked out similar apparatus.

Brown Motors Settlement Sought by Stockholders

MOLINE, ILL., Jan. 18—Pending the outcome of court litigation, it was voted to postpone the annual meeting of the stockholders of the Brown Motor Co. for thirty days. The litigation now before the courts involves the relationship of President Walter F. Brown to the stockholders. The postponement of the meeting was agreed to by the executive. Preliminary to the annual meeting, an effort will be made to arrange a settlement. President Brown has intimated that he would be willing to accept $15,000 for his interests in the concern in lieu of the proposed dissolution. An informal counter offer of $5,000 was proffered subject to the approval of the stockholders. It is possible that concessions will permit an amicable adjustment of the controversy. President Brown invented an internal combustion engine for motor vehicles and the company was organized to manufacture the invention in quantities. When the postponed meeting is called for Feb. 10, it is expected that the settlement will be reached.

M. A. M. A. Directors Name New Officers

E. H. Broadwell Succeeds C. E. Thompson as President—Two Changes on Board

NEW YORK, Jan. 17—Directors of the Motor and Accessory Manufacturers Association at an organization meeting following the annual session of the members elected E. H. Broadwell, vice-president of the Fisk Rubber Co., as president to succeed Charles E. Thompson, president of the Steel Products Co., who had served two terms.

Other officers elected were: First vice-president, W. O. Rutherford, vice-president of the B. F. Goodrich Co., second vice-president, A. W. Copland, president of the Detroit Gear & Machine Co., third vice-president, H. L. Horning, secretary and general manager of the Waukesha Motor Co.; treasurer, L. M. Wainwright, president of the Diamond Chain Co.; secretary and assistant treasurer, G. Brewer Griffin; general manager, M. L. Heminway.

Two new directors were elected to the board to take the places of Christian Girl and E. W. Beach. They were F. C. Glover, vice-president and general manager of the Timken Detroit Axle Co., and H. L. Horning. Other directors besides these two and the officers are: C. E. Thompson, retiring president; J. M. McComb, vice-president of the Crucible Steel Co.; G. W. Yeoman, treasurer of the Continental Motors Corp.; C. H. L. Flinterman, vice-president of the Detroit Pressed Steel Co., and E. P. Hammond, president of the Gemmer Manufacturing Co.

The annual gathering of the association this year was one of the most successful ever held and a large number of new members were elected. It has been demonstrated that the legal and credit departments are of special value to members and this work is steadily increasing in importance. The work of Sidney S. Meyers, the general counsel, has expanded to such an extent in the past few months that it has been found necessary to add materially to his staff of assistants. The efforts of the credit department are along constructive lines and every effort is being made to save companies which are solvent but hard pressed for ready cash.

The parts and accessory makers were much gratified by the results of the New York show and are as confident as the vehicle manufacturers that the tide has turned and that business will improve from now on, although the upward trend will be gradual. It is significant that the relations between car and parts manufacturers are becoming more cordial.

OLIVER RIM OFFICERS NAMED

ATLANTA, Jan. 17—Elmer Oliver was re-elected president of the Oliver Rim Co., manufacturers of a new double jointed rim for automobiles, at the first annual meeting of the board of directors held Jan. 11 in Atlanta. C. E. Gregory was re-elected secretary and treasurer, and G. C. Whittaker, Southern representative of the Truscon Steel Co., was elected vice-president. The number of directors was increased to eight, the new members of the board being W. R. Massengale and J. S. Hollins, both of Atlanta; H. W. Crouch, of Johnston, S. C.; P. A. Redmond, of Aragon, Ga. The directors re-elected are Joseph A. Blount, F. A. Seegar, Neal Meier, all of Atlanta, and R. J. Aycock, of Pinewood, S. C.

Harvester Postpones Fort Wayne Plant Work

FORT WAYNE, IND., Jan. 17—All further work on the construction of the big new motor truck plant which is to be erected here by the International Harvester Co. has been suspended for two or three months according to local officials of the company. This action was taken following a visit to Fort Wayne by Cyrus W. McCormick, Jr., works manager for the concern.

Unfavorable business conditions over the country is given by Harvester company officials as the reason. However, assurance is given that just as soon as business conditions have improved the work started here will be taken up again and will be continued without further interruption. According to the officials it is not thought that it will be necessary to suspend operations for more than two or three months.

A great quantity of material for the plant is now on the grounds. A large part of the work on the belt line railroad which will connect the plant with the local railroads has been finished.

Receiver Appointed for Superior Truck

ATLANTA, Jan. 17—An involuntary petition in bankruptcy has been declared against the Superior Motor Truck Co., manufacturers of the Superior Truck, and Federal Judge Samuel H. Sibley has named Walter P. Andrews as receiver pending the outcome of the bankruptcy proceedings. The petition followed a verdict rendered against the truck corporation in the Federal court here Jan. 12, in favor of the Beaver Mfg. Co., for $2879. The petition was instituted by Hubbard Brothers, and the Shearer Machine Co., Atlanta, and the L. C. Case Co., Boston. The truck company is alleged to owe large sums to various creditors and to be insolvent.

VICTOR ON 300 DAILY BASIS

SPRINGFIELD, OHIO, Jan. 17—President H. H. Durr, of the Victor Rubber Co., declared today that the plant has been placed on a schedule of 300 tires daily, that this number will be increased gradually and that 140 men are at work. "The situation is clearing," said he, "I expect rapid resumption of business." The company plans an extensive advertising campaign.

Sales Restriction Charged to Jobbers

Canadian Tariff Board Asked by Dealer to Dissolve Alleged Combination

OTTAWA, ONT., Jan. 15—At the tariff inquiry just held here, R. L. Phillips of Phillips & Pringle, Fredericton, N. B., charged that business in automobile accessories was being unduly restricted in Canada. He claimed that this was due to the organization of jobbers once known as the Canadian branch of the National Association of Automobile Accessory Jobbers, but now known as the Automotive Equipment Association.

He asked that consideration should be given to the question of taking action under the Criminal Code or under the Combines Act to dissolve this "trust." He requested that the products of houses manufacturing automobile accessories, and who had little or no competition in Canada, and the sale of whose goods was practically confined to members of the Automotive Equipment Association, should be placed on the free list.

He requested, further, that legislation be passed next session to provide that a judge of the Supreme Court in any province, or other suitable person, might be empowered to investigate charges that the distribution of Canadian manufactured goods was being unduly restricted.

Vermont to Develop Airway Possibilities

MONTPELIER, VT., Jan. 15—The early establishment of landing fields in Vermont to keep pace with the progress of aerial transportation was urged as a means of developing the state's resources, in the inaugural address of Gov. James Hartness.

He pointed out that in each previous stage of transportation development, Vermont had been handicapped by its lack of navigable rivers and the ruggedness of its surface which made railroading difficult and costly, but that by taking timely action the state could be on even terms with others in air transportation.

"Our cost of road construction and our ever increasing cost of maintenance will more and more force us to use the airway which is all ready for use and costs nothing for maintenance," he said. "The future growth of towns will depend in a large measure upon the alertness in making provision for safe landings for aircraft. The landing fields are practically air ports.

"By the establishment of facilities of this kind our flying service will begin without further expense. I recommend an investigation of the needs of amending present statutes or enacting new statutes for facilitating the acquisition of landing sites by towns or under proper state or town control of private initiative."

Cincinnati Prices Firm for Present

Lower Wage Rates Prevailing as Industry Resumes—Look for Good Business

CINCINNATI, Jan. 17—Optimism has the right of way among the automobile and truck manufacturers around Cincinnati. Without exception they all are preparing for an increased demand. Labor trouble is believed to be a thing of the past and the men are showing a very different attitude toward their jobs than they did last year. In none of the plants has there been any general reduction of wages, but in some of them where men who were laid off during the slack times are being re-employed, they are being cut 20 to 25 per cent in wages.

M. Schacht, of the Schacht Motor Truck Co., said they are besieged by men looking for work who are willing to take the cut made, or an even greater one if necessary, to get employment. He emphatically states, however, that any reduction of wages cannot affect the price of trucks for the present, for there has been no great decline of materials.

The United States Motor Truck Co. has made no reduction in wages and contemplates making none for the present, according to General Manager F. J. Alvin. Only efficient men now are employed in that plant and men must produce if they expect to hold their jobs. Alvin does not believe there is any possibility of reducing the price on trucks for some time under present costs of material and production.

The Sayers & Scovill Co. is operating with about 85 per cent of its normal force. They have not laid off any men, but as men left they did not fill their places. They have not made any reduction in wages and are not contemplating any for the present. The plant operates on the piece-work basis.

The Armleder Truck Co. is operating all departments, but with a reduced force. No reduction in wages has been made, but just what will be done when the plant resumes full operations has not been decided upon. Manager Woodruff of the sales department said he could not see how it would be possible to make any reduction in the price of trucks for some time.

Armleder is preparing to send a man to Europe, where the prospects for a revival of export trade are said to be growing brighter. He will go to England, France, Scandinavia, Holland, and will also look into the possibilities of India. The company is planning a big campaign for business in Cuba and preparing to go after business in Mexico.

RANGER TRACTOR ADVANCED

HOUSTON, TEXAS, Jan. 15—The selling price of the Ranger tractor-cultivator manufactured by the Southern Motor Mfg. Assn., was advanced today from $1250 to $1375. This price includes cultivator gangs.

AERONAUTICS RECORD STEADY DEVELOPMENT

NEW YORK, Jan. 15—Notwithstanding many handicaps such as lack of aerial laws, landing fields and a strong government policy, there was a steady development in aeronautics in this country last year. Among the more important events were:

Flight to Nome, Alaska and return, from Mineola, a distance of 9,000 miles in 112 hrs. flying time by four Gallaudet remodeled DH.-4-B planes piloted by officers of the army air service.

The air mail operating between New York and Washington, New York, Chicago, Cleveland, Omaha, Salt Lake City and San Francisco transported approximately 100,000,000 letters at ordinary rates.

Aerial survey of the Panama Canal Zone made by the Navy.

Coast line of Haiti mapped by the Geological Society co-operating with the Marine Corps.

World's record altitude of 33,000 ft. established by Major R. W. Schroeder in an American designed and built Packard-LePere bi-plane.

Andes Mountains crossed by Donald Hudson in a Curtiss "Wasp" at an altitude of 30,000 ft. above sea level.

Flight by a Junker monoplane from Omaha, Neb., to Lancaster, Pa., without stop.

Production by the Wright Aeronautical Corp. of a cannon motor discharging 1½ lb. shells from the propeller shaft of an airplane in flight.

Kentucky Tire Receiver Asked in Second Suit

LOUISVILLE, Jan. 17—Ink was hardly dry on an order dismissing an action for a receiver for the Kentucky Tire & Rubber Co. in the Circuit Court yesterday when another similar action was filed, and it will be necessary for the officials to make another defense.

It was alleged in the petition that the officers of the company failed to begin operation of a factory in Louisville by Jan. 1 for the manufacture of automobile tires, and that the assets of the company were being dissipated by the payment of exorbitant salaries.

In dismissing the proceeding yesterday it was stated that the officers of the company waived any claim they might have had for damages against the petitioners on account of the proceedings. Those named parties to the two suits are H. P. Dedriksen, president; W. R. White, vice president, and J. E. and O. R. Peterman and A. D. Hite.

CAMP GRANT SCHOOL STARTS

ROCKFORD, ILL., Jan. 17—Equipped at a cost of $2,000,000, the automotive school at Camp Grant is now in operation with an enrollment of 400 students in the eight departments, each with its own experts and equipment. Captain John C. Daly heads this army school, assisted by Lieut. Roderick A. Stamey.

Cleveland Retains Men at Old Rates

Reductions Made in Only Individual Instances—No Surplus of Skilled Men

CLEVELAND, Jan. 17—Cleveland automobile manufacturers are not taking advantage of present economic conditions to arbitrarily force down wages faster than the cost of living declines. Manufacturers agree that the present is an opportune time to build up a morale in their factory organizations for the future when business regains a normal condition. They agree that the morale can be built up by not taking un unfair advantage of labor at this time.

Some factories in Cleveland have reduced wages slightly, from scales that were imposed on automobile makers by abnormal conditions. Spring prices have not been made, and at this time no one could say what would be done in this respect as a result of labor conditions. There is not a surplus of skilled automobile mechanics here, although there is a surplus of semi-skilled men.

At the White Motor Co. the number of employees for January, 1921, is 6218, while a year ago the number was 5826. On Dec. 1 the men at this plant were notified that beginning Jan. 1 they would work five days a week. They had been working 49 hours a week; under the new schedule they work 45. The night force, which had been working 50 hours a week, and paid for 75 hours, was notified that in January they would work four nights one week, five nights the next week, and that they would work 10 hours a night and be paid for 15 hours. The men were notified Jan. 1 that on Feb. 1 they would work eight hours a day for four days each week, or 32 hours a week, and this proposal, as well as the first one, was gracefully accepted by the men. There has been no reduction in wages at this plant.

The Chandler Motor Car Co. is maintaining 70 per cent of its working force five days a week. This is an increase of one-half day a week over December. There is no surplus of skilled help at this plant.

Winton Reduces Some Wages

At the Winton plant they report there is no surplus of automobile mechanics, but that there is a great surplus of semi-skilled men. Some of the employees who have been retained at the Winton plant received reductions in wages ranging from 15 to 20 per cent.

At the Templar factory all employees have received a 20 per cent reduction, and in view of the economic conditions the reduction was accepted gracefully.

At the Grant Motor Car Co. there has been no reduction in the pay of old employees with the exception that the 10 per cent bonus has been taken off. All new men hired are taken on at 10 per cent less than the rates paid the old employees of the company.

$637,500,000 in Fund For 1921 Road Work

Total Available for Highways in 48 States Doubles Panama Canal Cost

NEW YORK, Jan. 17—For public highways—$637,500,000.

This is the staggering total available in the 48 States of the Union for expenditure this year on road construction. The total includes Federal, State and county appropriations. This amount is nearly 50 per cent more than was spent in ten years in building the Panama Canal and nearly six times as much as New York State spent on its great barge canal.

The amount is the largest ever made available in any one year for road building, and it is believed that with materials lower in price, labor plentiful and transportation normal, the mileage of construction will surpass any previous mark. A quarter of the total comes out of the Federal aid fund, and this source of supply will be exhausted by the beginning of 1922 unless additional funds are provided by Congress, which is not likely at this session which has "economy" as its slogan.

With such an enormous amount to be used in road building, the various agencies interested in improvement of highways are actively concerned in having it expended wisely and economically. The main purpose is to have the roads built where they will do the most good and carry the most traffic. The subject of substantial and economical construction is next in importance. One of the important factors in lower costs is found in the fact that labor is not only plentiful but cheap. Common labor for road building is available in some of the Southern States at $1.50 a day.

Army Planes to Fly Cross Country in Day

WASHINGTON, Jan. 17—The Chief of Air Service, United States Army, officially announced that on Feb. 22, 1921, an attempt will be made to cross the United States by airplane within a period of 24 hours.

The route chosen extends between Florida and Southern California. The starting point in Florida will be Pablo Beach, Jacksonville, and the starting point in Southern California will be San Diego. The former point is within the 8th Corps Area and the latter point is within the 9th Corps Area. The distance flown will be 2079 miles. There will be two participants in this flight. Lieut. Alexander Pearson, Jr., will take off from Pablo Beach, Florida, making the flight in three hops; from Jacksonville, Florida to Ellington Field, Houston, Texas, 804 miles; from Ellington Field to El Paso. Texas. 660 miles; from El Paso to Rockwell Field, San Diego, Cal., 615 miles. The participant from San Diego, whose name has not been announced, will reverse this schedule, making the flight on the same day.

It is believed that this flight will produce records of performance which will be of extreme interest in the furtherance of both commercial and military aeronautics and will be the first in history in which the United States has been completely traversed in so short a period of time.

Trucks to Be Shown at Tractor Exhibit

COLUMBUS, Jan. 15—After considering the question for some time, the executive committee in charge of the National Tractor Show, which will be held at Columbus, Feb. 7 to 12 inclusive, has decided to admit trucks to the exhibits. This action was taken at a meeting of the executive committee in Chicago recently when the Columbus committee made such a recommendation. Attending the meeting were W. J. Longbon, chairman of the local committee and E. E. Whaley, manager of the show.

The space to be allotted to truck manufacturers will be plotted in the near future and contracts for space will be closed. This space is somewhat limited, although very desirable and is located in the Coliseum, which is the central building used for the show. There will be space for from 30 to 50 trucks.

This action of the committee meets with the approval of many people who have urged that trucks, especially those used for farm work be admitted to the show. It was urged that since the teachings of the show is the motorization of the farm, trucks could not be excluded.

Army Develops Machine to Test Brake Linings

WASHINGTON, Jan. 17—The Engineering Section, Motor Transport Division, in connection with the Bureau of Standards, has developed a machine for testing brake-lining. Manufacturers of brake-lining who may be interested are requested to send ten feet of ¼ x 2-in. of their standard lining to the Motor Transport representative at the Bureau of Standards. These samples are to be sent by Parcel Post, prepaid, and addressed to R. B. Burton, Motor Transport Representative, Room No. 238, Industrial Building, Bureau of Standards, Washington, D. C. Any communications regarding the tests should be addressed to the Motor Transport Depot, at Camp Holabird, Md.

RENTZ SPARK PLUG FORMED

ATLANTA, Jan. 17—The Rentz Spark Plug Co., manufacturers, has been organized and incorporated in Atlanta with $500,000 capital, by W. C. Rentz, P. H. Orr, Asa G. Candler, Jr., John S. Hurt and George D. Webster. The company will establish a large plant here for the manufacture of the Rentz spark plug, invented by W. C. Rentz.

New York Road Plan To Increase Car Tax

Responsibility for Maintenance Means Addition of $1,000,000 to Present Rates

NEW YORK, Jan. 17—Through the placing of responsibility for the maintenance of New York State highways solely upon motor vehicle owners, as advocated by Governor Miller and as expected to be approved by the Legislature, an additional burden of at least $1,000,000 in taxes will devolve upon owners. This is the estimated difference between road upkeep expense and the present return from motor vehicle sources.

Legislative sanction will be accorded the plan outlined by Governor Miller in his first message to the lawmakers, according to Senator Charles J. Hewitt, who has been named chairman of the Senate Finance Committee.

"A slight increase in horsepower rates on each passenger car will make up the required revenue," Senator Hewitt said. "I also believe that motor trucks should bear their part in the contemplated increase in proportion to that saddled upon passenger car owners. Trucks have never borne their share of the motor vehicle tax."

During 1920, automobile owners paid about $9,000,000 to the State for licenses, etc. One-fourth of this was turned back to counties, as provided by law, for county road work. About $7,500,000 was spent by the State Highways Department in maintenance work. Maintenance for the fiscal year had been estimated at $15,000,000, but this will be reduced by the Legislature in view of the proposed method of raising the fund.

YOUNGSTOWN CARRIAGE SOLD

YOUNGSTOWN, Jan. 17—Sale of the buildings, land and fixtures of the Youngstown Carriage Co., to the Henderson-Overland Co., has been completed. The price was about $300,000. Possession will be given to the purchaser April 1. The Youngstown Carriage Co. sold Studebaker passenger cars and Federal trucks. These lines have not been placed with new representatives. The Henderson-Overland Co. is distributer for the Willys-Overland line of passenger cars, the Handley-Knight, and the Garford truck. It will continue these lines.

PUMP COMPANY RESUMES WORK

FORT WAYNE, IND., Jan. 17—Operations at the Wayne Oil Tank & Pump Co. were resumed today with about three-fourths of all the employees on duty. About 150 workers will continue to remain idle until repairs and moving of machines at the plant are completed. It is expected that these workers will be given employment in a short time. The company manufactures tanks and storage systems for filling stations, etc.

Tractor Show Topics Cover Many Points

Noted Experts on Agriculture to Speak to Farmers at Columbus Exhibit

COLUMBUS, Jan. 17—The most comprehensive educational program ever arranged for a large gathering of American farmers will be the main feature of the coming National Tractor Show, which will be held in Columbus Feb. 7 to 12 inclusive. Farm problems of every kind and every phase of tillage of the soil will be touched upon during the show in the educational program. Methods of handling, caring for and repairing farm machinery will also be touched upon at the meetings.

The men selected to explain the various farm questions are authorities in their lines. One of the speakers will be F. I. Mann, of Gilman, Ill., a brother of Congressman Mann on "Soil Conservation," Hammond Olney of St. Joseph, Mo., editor of "Power Farming," will speak on "Adapting the Farm and Farm Business to Power Farming."

"Factors Which Determine the Type and Size of Tractor to be Purchased" will be explained by I. W. Dickerson, Charles City, Iowa, editor of the Agricultural Engineer. "The Modern Trend of Tractor Design," is the subject to be treated by J. B. Davidson of the Iowa State College, Ames, Iowa. Prof. O. W. Sjogren of the College of Agriculture of Lincoln, Neb., will talk on "Ignition Troubles and Their Remedies." "Tractor Hitches" will be explained by Prof. Daniel Scoates of A. & M. College, College Station, Texas.

Two Ohio State University professors will be on the program. They are G. W. McCuen and F. W. Ives. The former will lecture on "Lessons to be Learned from a Tractor Survey in Ohio" and the latter on "Housing the Tractor and Tractor Tools."

Purdue University is sending Professor William Aikenhead who will talk on "The Tractor and Belt Power" and Pennsylvania State College is sending Prof. R. U. Blasingame to talk on the "Advisability of Purchasing Tractors and Tractor Tools in Community Groups." F. W. Duffee, a former student at the Ohio State University will explain "Laying off the Field for Plowing." Practical farmers will also be on the program and it is planned to have general round-table discussions of all questions pertaining to farming and tractors.

DART TRUCK NAMES OFFICERS

WATERLOO, IOWA, Jan. 17—The following officers have been elected by the directors of the Dart Truck & Tractor Corp., President, C. C. Wolf; vice-president in charge of engineering, W. H. Johnson; vice-president in charge of sales, M. D. Herron; secretary, G. J. Bondurant. The company still is in limited production but reports showed that prospects are bright for 1921.

ROLLS-ROYCE TOASTS FIRST AMERICAN CAR

SPRINGFIELD, MASS., Jan. 17—A dinner was given by the officers of Rolls-Royce of America, Inc., to the foremen and heads of departments to celebrate the completion of the first chassis built in the plant here under English supervision. The chassis now on test is American built even to the radiator. Preliminary operations were begun at the American works on July 12 and have been almost constantly under way since that time. The company now has on hand in this country more than $1,500,000 worth of unfilled orders. The dinner was attended by about 50 of the English experts in charge of production. L. J. Belnap the president, was toastmaster.

Elwood Company Formed to Build New Tractor

MADISON, WIS., Jan. 15—Production on a new design of two-wheel tractor will shortly be started by the Elwood Tractor Co. of this city. The designer is C. D. Elwood, who has long been connected with the farm machinery business, having represented the McCormick company, Parlin & Orendorff and the American Seeding Machine Co. in Canadian territory. In 1908 he was with the Hart-Parr Co. In the fall of 1914 he began a course of study in mechanical engineering at the University of Wisconsin.

The Elwood machine is similar in appearance to the Moline Universal and the Allis-Chalmers small model. Development work on the tractor has been going on four years and the last model built is the ninth. Madison has not yet been definitely selected as the location for the factory.

The officials of the company are W. H. Heddles, president; C. D. Elwood, vice-president; H. A. Burd, secretary and treasurer.

LEONARD BUYS HEGGIE PLANT

GRIFFITH, IND., Jan. 17—Leonard Tractor Co. of this city, has purchased the James C. Heggie & Sons Co. plant in Joliet, Ill., and will manufacture a four wheel drive farm tractor. The plant at Griffith will be removed to Joliet at once and it is hoped to start production early in the spring. H. M. Leonard, inventor of the tractor, is president and general manager of the company. His headquarters are at Gray, Ind., and he was formerly connected with the Jackson Automobile Co., and also was special engineer with the Lewis Truck Co. In 1914 he designed a truck for the Duplex Truck Co. F. E. Parks and A. A. Parks, both of Joliet, are interested in the company and will assist in the financing. John Hurlburt of Gary, Ind., is secretary-treasurer. When in full operation the plant will produce five machines per day.

Maxwell Concurs in Creditor's Suit

Petition Filed by Jenks & Muirs in Suit for $6,064 Accepted by Company

NEW YORK, Jan. 18—The Maxwell Motor Co., Inc., has concurred with petitions filed by the Jenks & Muirs Mfg. Co. of Detroit for an injunction restraining creditors from interfering during the pendency of a suit for the recovery of $6,064 as well as for the establishment of claims of creditors and assets. The action was filed in United States District Court in Detroit.

In the bill of complaint the manufacturing company states that about 150 other creditors hold claims against the Maxwell company. These claims approximate $4,000,000, the petition states, and it is added that other indebtedness in the form of loans brings the company's total liabilities to $16,000,000.

The petition states that the Maxwell company has assets aggregating more than $25,000,000 but that this cannot be converted into cash at this time without great loss. The plaintiff contends that the immediately realizable assets of the Maxwell company are not sufficient to meet the claims of creditors.

There has been considerable speculation as to why the company has concurred with the petition, but no statement has been forthcoming from the management committee which recently declared operative the plan for a consolidation of the Maxwell and Chalmers company. Not all the stock of the Maxwell company has been deposited under this plan. It is understood there are outstanding about 20,000 shares of the second preferred stock and about 31,500 shares of the common stock.

Persons familiar with the affairs of the Maxwell company believe it possible that this suit may be designed to force the owners of the outstanding stock to give their consent to the plan under penalty of being excluded entirely from its benefits. It is not believed the suit will have any effect upon those stockholders who have assented to the plan.

BERGOUGNAN COMPLETES PLANT

TRENTON, N. J., Jan. 14—Construction work has been completed on the new factory units undertaken several months ago by the Bergougnan Rubber Corp. and it now has one of the most modern and complete tire plants in the East. The work was continued notwithstanding the slump in the tire market. The plant will produce pneumatic tires for passenger cars, motor trucks and motor cycles as well as inner tubes for its tires. The company has invested several hundred thousand dollars in enlarging the factory, machine shop and storage facilities. Provision has been made for the comfort of the employees and the new building includes an up-to-date cafeteria.

Congress Considers Revision of Tariff

N. A. C. C. Committee Heads Show Possibilities of Foreign Trade Development

WASHINGTON, Jan. 14—Establishment of a uniform tariff rate of 30 per cent on automobiles and a national policy of reciprocal relations were advocated to-day by J. Walter Drake, chairman of the foreign trade committee of the National Automobile Chamber of Commerce at a hearing before the House Ways and Means Committee. The proposal for a revision of the tariff downward and reciprocity aroused great interest in Congress because practically all other industries were demanding higher rates as a protection against foreign competition.

Though it is quite too early to predict the action of the Ways and Means Committee, indications were that the Committee had been impressed with the proposition that the tariff duty on the higher priced cars should be reduced from 45 per cent to a basis of 30 per cent, which now prevails for the lower priced automobiles. Drake made it clear that the revenues would not be reduced as a result of this proposed cut in rates, but on the contrary, would stimulate importations of the higher priced automobiles.

"The imports of high-priced cars during 1920 amounted to 6 per cent," Drake said, "and those of lower priced motor vehicles to 94 per cent of total automobile imports. According to numbers there were 50 high-priced and 654 low-priced cars. The revenue from the former was $99,305 and $153,986 from the latter.

"The smaller number consisted of automobiles selling in the country of origin at more than $2,000.

"Reason for smaller imports of that type of vehicle may be ascribed to higher United States duty. With a uniform duty of 30 per cent, however, the imports of higher priced cars will proportionately increase, and consequently result in higher revenue. Despite the fact that this measure may directly affect their interests, American manufacturers of high-priced cars are adherents to this policy, believing it of general benefit.

Can Change with Conditions

He pointed out, however, that the present recommendations have to do only with existing economic conditions and does not necessarily foreclose the automotive industry from advocating a rearrangement as conditions warrant.

According to the chairman of the N. A. C. C. foreign trade committee, stabilization in the industry must be brought about by the cultivation of foreign markets.

"At the present time," he said, "the export trade is considerably hampered by great depreciation in foreign exchange. To afford manufacturers in countries with depreciated currency opportunity to sell their products in the United States will tend to right this condition. Although it is fully realized that the increased imports of automobiles, even if the duty on high-priced cars is reduced, will not be such as to materially improve the exchanges, still even minor influences of this kind, if multiplied in other trades that will not be greatly affected thereby, are certain ultimately to bring about the desired results."

Chairman Fordney manifested considerable interest at the mention of the retaliatory measures adopted by the French last summer. Various committee men questioned the witness about this phase of foreign trade of the automobile industry.

Cites Action by French

That favorable results from a uniform duty may be expected, it was said, is shown in the action of the French automobile manufacturers, who informed their government that the English, Belgian, Italian and French syndicates had collectively voted for a uniform tariff of 33-1/3 per cent. This duty was to apply to all automobiles imported into and from any of the countries that entered into the agreement. The French Ministry, however, cited the United States tariff of 45 per cent on automobiles of over $2,000 in value, and fixed the French duty at that rate on automobiles of the type most exported from the United States. It also added that a further reduction may follow if American duty should later be reduced.

The Committee was informed that American cars represent the greatest value for every dollar of cost. Statistics were submitted showing the differences in prices and horsepower of representative American and foreign machines. The data stressed the fact that the advantage remained with American manufacturers.

Drake further contended that reciprocity was essential for the expansion of American foreign trade. He stated that a uniform rate and reciprocal relations would stimulate trade in that the rate would apply to motor vehicles from such countries only as grant equality of treatment for American products.

As to the advantages of reciprocal measures, the committee was advised that wherever countries discriminated against American trade, there should be applied additional duties to be determined by law or expediency. Drake suggested that the President should have the power to ascertain what countries discriminated against the United States in tariffs and take protective measures.

Aluminum Tariff Opposed

Opposition of the automotive industry to proposed increases in tariff duties on aluminum, was made known to the Ways and Means Committee by G. A. Bauer of the N. A. C. C. foreign trade committee. He declared that automobile manufacturers were the largest individual users of aluminum and higher tariffs would mean adoption of cheaper substitutes.

Treasury Revises Excise Tax Clauses

Change in Computing Retail Tax —Define Overpayments— Simplify Export Rulings

(*Continued from page* 137)

can be manufactured only for such dealer or jobber and that it will be sold by such dealer or jobber as the manufacturer, the dealer or jobber is held to be the manufacturer for the purpose of the tax.

Revision of Article 34 allows the manufacturer who sells both at wholesale and retail to arrive at the basis of tax with respect to retail sales. The law provides that in such a case the manufacturer may base the tax on a retail sale on the price for which like articles are sold by him at wholesale. The revised regulations permit the manufacturer to arrive at this average by taking his actual wholesale sales for a given month and using this average until such time as his records show a material change.

Article 41 has been amplified to define in detail the difference between an "overpayment or overcollection" as distinguished from an "illegal or erroneous" payment or collection. The law permits a taxpayer to take credit for an overpayment or overcollection whereas an illegal or erroneous payment or collection must be recovered through a claim for refund of the excess payment.

Articles 42 and 43 have been practically rewritten with a view to simplifying them. Under Regulations 47, Revised, an article is regarded as having been sold for export if the manufacturer has in his possession at the time title passes or of shipment an order or contract of sale or document incidental thereto, or a certificate from the purchaser to the effect that the article is to be exported prior to use, re-sale, or further manufacture in the United States. This is held sufficient proof that the article in question is sold for export and provides temporary exemption from the payment of tax for a period of six months.

Must Submit Proof of Export

Before expiration of this six months period in order to establish the fact that the article in question has been exported in due course it is necessary for the manufacturer to have in his possession certain proof of exportation, which shall consist of a certificate of exportation filed with the manufacturer by the purchaser or in the case of a direct exportation by the manufacturer, of a copy of the export bill of lading or a certificate of the export carrier showing exportation of the article. Where such proof of exportation is not furnished within such period of six months it is necessary for the manufacturer to pay the tax on the article in question, and if subsequently the proof of exportation in due course is furnished, the manufacturer may make claim for refund of the amount of tax so paid.

Truck Sales Backed by New Corporation

Manufacturers Trust Organized in Chicago with $10,000,000 Capital to Aid Dealers

CHICAGO, Jan. 15—As a solution of the financing problems of the motor truck manufacturers on which David Thomas, general manager of the Motor Truck Manufacturers Association, has been working for some time, the Manufacturers Trust, a $10,000,000 finance company, has been organized here with Col. C. R. Vincent of the Vincent Trust of this city as president.

Although the company has been formed largely through the instrumentality of Thomas as general manager of the association, his aim being to obtain "methods of financing that would be sound and flexible enough to meet all the requirements of the motor truck manufacturer who is conducting his business on a sound safe basis," it is in no way connected with the Motor Truck Manufacturers Association itself.

The methods by which the Manufacturers Trust hopes to attain its purpose of meeting the reasonable financial requirements of the motor truck business from the manufacturer to the user are co-operative but the amount of stock the manufacturer may purchase has been limited to $15,000 or 1500 shares of a par value of $10. This has been due to the feeling that the manufacturer can well use his money in the manufacturing end of his business and that to require him to place a large amount in a finance company to finance his time sales would be like requiring him to "raise himself by his own boot straps."

The finance committee of the company, which passes upon the soundness of every undertaking, is composed entirely of bankers so that no partiality may be shown the manufacturers who may be stockholders in the company.

The position of the dealer is explained in this wise:

Dealers Afforded Wide Benefit

"The local bank is the corresponding bank which passes on any transaction between the local dealer and the user involving the Manufacturers Trust, this, of course, with a complete knowledge of the methods and policies of the Manufacturers Trust. In this way the local dealer wherever he may be located is afforded the benefits of a local finance company plus the facilities of a big company doing business nationally.

"The dealer of the manufacturer who has stock in the Manufacturers Trust is encouraged to buy a small amount of stock in the Manufacturers Trust more as evidence of good faith than anything else, unless it be the stabilizing influence that the convention might have upon the dealer himself and the closer relationship which this investment encourages between the dealer and the manufacturer."

TO OPERATE TRUCKS ON RAILWAY TRACKS

WINCHESTER, VA., Jan. 15—The Winchester & Western Railway Co., whose line from this city to Wardensville, W. Va., is almost completed, has successfully worked out a plan whereby powerful motor trucks, equipped with flanged wheels will be used instead of steam locomotives.

The passenger and freight trains will be shorter than those usually hauled by steam power, but there will be more trains. Practical tests recently made with a small automobile led the officials of the company to experiment with powerful trucks, and the scheme has been found to work admirably. Trains will be running into Wardensville within a month, it is declared. That town has assumed a "boom" atmosphere.

Studebaker Produced 52,000 Cars in 1920

SOUTH BEND, IND., Jan. 17—The Studebaker Corp. turned out 52,000 motor cars in the year ending Dec. 31. Its best previous production was 38,300 cars in 1919. The company reports that the total of unsold cars on hand is only 1600 or about two weeks supply. Both the South Bend and Detroit factories have resumed operations on the basis of an output of 800 cars a week equally divided between the two plants. The company will devote its efforts exclusively to the manufacture of automobiles, having disposed of its old farm wagon business to the Kentucky Wagon Co. of Louisville, with the right to use the Studebaker name for two and a half years.

Nash Boosts Output to 40 Cars Daily

KENOSHA, WIS., Jan. 14—Former workmen to the number of 2000 have been re-employed by the Nash Motors Co., which has been operating with a greatly reduced force. Its output is now forty cars daily, and it is planned to return to normal as quickly as conditions warrant it.

DUTY MOTORS TO MAKE TRUCK

CHICAGO, Jan. 15—The Duty Motor Corp., which has been incorporated for $500,000 under the laws of the State of Illinois, is manufacturing a 2-ton capacity truck which sells for $1,490, and is contemplating the erection of a large factory in the early spring in Greenville, Ill., to increase production. The following have been elected officers of the corporation: President, W. H. Ruther; vice-president, W. J. Gubser; secretary-treasurer, J. P. Snowden, and sales manager, Paul Harnetiaux.

Half of Car Sales on Part Time Basis

Acceptance Corporation Statistics Show Necessity of Credit—Farmers Aided Most

NEW YORK, Jan. 17—Statistics gathered by the General Motors Acceptance Corp. through the issuance of a questionnaire to dealers show that between 45 and 50 per cent of all automobiles being sold in the United States today are marketed on some deferred payment system. This is considered the first authoritative figure issued covering this difficult point. The replies from dealers covered sales of 149,136 cars of which 69,729 were sold on time.

The period for which the questionnaire asked information was that from Aug. 1, 1919, to July 31, 1920, and therefore includes the latter half of a summer selling season, the following fall, winter and spring seasons, and the first half of the succeeding summer. Selling conditions over a full yearly cycle are thereby exemplified.

City dwellers paid cash more frequently than farmers, only 44.9 per cent of urban sales being on credit arrangements, while 48.2 per cent of new cars delivered to farmers were on time. On trucks 53 per cent of those sold in cities were financed while 59.9 per cent were financed of those sold to farmers. Maximum time allowed to city dwellers on deferred payment sales averaged 9.3 months and to farmers, 11.1 months. The average down payments on all deferred payment sales was 40.3 per cent of the cash selling price.

Commenting on the statistics, the corporation asserts that by more intensive use of deferred payment facilities the automobile industry may be able to increase its sales by approximately 25 per cent. This is based on the estimate by economic experts that 25 per cent of the industry's production always will be sold for cash.

Bankers Take Over Control of McGraw

(*Continued from page* 138)

of plant executives. The McGraw Tire and Rubber Co., was organized in 1910 and until the present time it had been prosperous, paying to stockholders approximately 88 per cent in cash dividends and 86 per cent in stock dividends. The present capitalization is $2,500,000 of preferred stock and 100,000 shares of no par value common.

The action taken is expected to strengthen the position of preferred stockholders, assure a vigorous and businesslike management and the prediction was made that the company will come through O. K. E. S. McGraw, one of the organizers and for many years head of the corporation died a year ago and Morgan succeeded him as President.

Unsecured Creditors Delay Goodyear Plan

Highly Optimistic Reports on Rehabilitation of Company Considered Premature

NEW YORK, Jan. 19—Conferences of representatives of the various banking groups which are interested in the reorganization of the Goodyear Tire & Rubber Co. are being held here almost daily, but one of the leading factors in the refinancing program declared to-day it was impossible to forecast accurately what the result would be, although everyone concerned was hopeful a solution satisfactory to all would be worked out.

Highly optimistic reports, which have been current in financial circles the past few days, are somewhat premature. The chief stumbling block to the success of the negotiations is the attitude of the merchandise creditors. A large banking house has agreed to underwrite an issue of first mortgage bonds which it has been proposed to issue for the further protection of secured creditors. In connection with this proposal is another to issue junior securities in the form of 20 year debentures and first preferred stock to the unsecured creditors. This plan is not satisfactory to a large proportion of those to whom bills for merchandise are payable. It is intimated, however, that unless this offer is accepted the only alternative is a receivership under which the merchandise creditors would have to take what they get.

Several new banking houses have been brought into negotiations, including J. P. Morgan & Co., and bankers who are interested in other tire companies are lending their aid because of the sincere desire to keep Goodyear out of the courts. It is realized that a receivership would have a bad psychological effect upon the entire industry.

Most of the conferences are being held in the offices of Paul D. Cravath, and they are being attended by bankers not only from New York but from Cleveland, Pittsburgh, Chicago and other cities. Among the participants are Charles H. Sabin of the Guaranty Trust Co., and James S. Alexander of the National Bank of Commerce of this city.

A definite decision must be reached before Feb. 15, when Goodyear must pay \$18,000,000 to the banking syndicate headed by Goldman, Sachs & Company.

G. M. TRUCK INCREASES OUTPUT

PONTIAC, MICH., Jan. 17—At the present time the General Motors Truck Co. in Pontiac is employing more than half of the normal working force and the number of men will be increased steadily as conditions warrant it. According to general manager, W. L. Day, the company will probably be in production on its five models in March. Production is now about nine a day on one light truck and in February production will be started on a second light truck.

Report Vim Bought by Standard Steel Car

PHILADELPHIA, Jan. 19—The Vim Motor Truck Co. has been reorganized and taken over by responsible financial interests. No announcement has been made as to the details of the transaction but it is understood the company has been purchased by the Standard Steel Car Co., which has plants at Butler and New Castle, Pa., and Hammond, Ind.

The Vim company resulted from a reorganization in 1915 of the Touraine company, which produced the Vim delivery cars. The company has devoted itself to the manufacture of commercial vehicles.

G. M. C. Makes Changes in Executive Personnel

NEW YORK, Jan. 17—At a meeting of the directors of the General Motors Corp. last Thursday, the resignation was accepted of W. C. Durant as a member of the finance committee and as a member and chairman of the executive committee.

The executive committee was designated as follows: P. S. du Pont, chairman; J. J. Raskob, J. A. Haskell and A. P. Sloan, Jr.

The resignation was accepted of F. W. Hohensee as a director, vice-president and member of the executive committee.

F. D. Brown was elected a member of the finance committee.

C. F. Kettering was elected a vice-president. A. H. Swayne was elected a director and vice-president.

Lewis Named Chairman of Tire Maker's Section

NEW YORK, Jan. 19—The tire manufacturers division of the Rubber Association of America has elected as its chairman Seneca G. Lewis of the Pennsylvania Rubber Co. and Joseph C. Weston of the Ajax Rubber Co., vice-chairman.

H. J. Zimmerman of the B. F. Goodrich Co., has been elected chairman of the traffic committee of the Rubber Association with A. D. Phillips of the Fisk Rubber Co., as vice-chairman.

C. W. Wilson of the Dural Rubber Corp. has been made chairman of the foreign trade division, with R. H. Daniels of Goodyear, as vice-chairman.

SIMPLEX RE-NAMES OFFICERS

CADILLAC, MICH., Jan. 17—The Simplex Wire Wheel Co. has re-elected the old board of directors and officers: President, J. P. Wilcox; vice-president, W. E. Curry; secretary-treasurer, J. C. Ford. The other directors are J. B. Wagner, W. A. Kyser, C. B. Smith, C. A. Saunders, George J. Sandel and C. F. Williams. The concern was formerly the Kolben Wheel Co., Detroit.

Interlocking Tire in Receiver's Hands

Stockholders and Minor Officers Join in Petition Alleging Mismanagement

AKRON, Jan. 15—Elihu Harpham, prominent Akron real estate operator, today took charge of the affairs of the interlocking Cord Tire Co. of Akron and Mogadore, following his appointment as receiver by Judge W. I. Ahern in Common Pleas court, on petition of several stockholders and minor officers of the company. They charge mismanagement and alleged fraudulent work upon the part of certain officials of the company. This petition is signed by shareholders, including E. E. Ammons, vice-president of the company; Walter G. Scott Herman; Gustave J. A. Gibson and W. Dorn.

The petition contains the allegation that the company attempted to buy real estate in Mogadore for its new plant without legal action upon the part of its directors and that the value of real estate is carried on the books at \$38,000 while only \$16,000 was paid. Charges also are made that bills and accounts receivable are listed at over \$63,000 while not more than \$30,000 can be actually realized on them; that the company's books show products valued at \$100,000 while the actual value thereof will not exceed \$50,000 and that the company is delinquent to the extent of \$8,000 in payment of wages and salaries to employees.

The petitioning shareholders further charge that officers of the company have received rebates on contracts awarded for construction of company buildings and that they have spent approximately \$115,847 as commissions on sale of stock. The company recently completed a new plant at Mogadore. The firm is capitalized for \$1,000,000 of which \$310,000 remains unpaid on subscription lists.

Walter Kline is president of the company.

Harpham was directed to-day to conduct an immediate audit of the company's books to determine the exact amount of assets and liabilities. The plant at Mogadore has been closed for several days due to shutting off of power by the Northern Ohio Traction and Light Co. through failure of the company to contract for power, the shareholders charge in their petition.

BULL TRACTOR REGAINS FUNDS

INDIANAPOLIS, Jan. 19—At a hearing held Jan. 12 before Harry C. Sheridan, referee in bankruptcy in the case of the Bull Tractor-Madison Motors Corp. of Anderson, the Royal Indemnity Co. of New York was ordered to pay to Fred Dickson, trustee of the corporation, \$15,000 deposited with it at the time the Bull Tractor Co. and the Madison Motors Co. were consolidated. The money was deposited by the tractor company to cover any revenue taxes incurred by the Madison company before the consolidation.

INDUSTRIAL NOTES

Automatic Products Corp. has succeeded the Tock Screw Machine Products Corp., taking over its assets and assuming its liabilities. There will be no change in personnel and the business of the company will be carried on as heretofore.

Robertson Resilient Wheel Corp., New York, has taken a long lease on space in the Armour Postal Station Building, Chicago, and will occupy it as general office of the company, about Feb. 1.

Mercury Body Corp. has been organized at Louisville, Ky., to build automobile bodies. A plant soon to be built will have a capacity for 6000 bodies a year, constructed under a new process.

Duesenberg Automobile & Motors Co. plans for the Indianapolis factory have been approved by Fred Duesenberg, vice-president and engineer, and construction will soon begin.

Cleveland Tractor Co. has opened a district sales office in St. Louis with S. C. Mitchell in charge. Territory covered borders the Mississippi from Illinois to the Gulf.

F. D. Wilson has been elected president of the Wilson Tractor Co., formed by him to build tractors at Ottumwa, Iowa. He was formerly with Deere & Co.

American Power Shovel Co. has removed its offices from Chicago to Milwaukee, where the main manufacturing activities of the company are centered.

Port Houston Tire & Rubber Co., Houston, Texas, has taken over the plant and property of the Universal Tire & Rubber Ass'n.

Master Rubber Co., Dayton, Ohio, has resumed operations with its full force of employees after a six-week layoff.

Sewell Cushion Wheel Co. showed an increase in business in 1920 of 61 per cent over the previous year.

Automatic Safety Tire Valve Corp. beginning Feb. 1 will handle sales direct from its New York office.

Pioneer Truck Co., Chicago, has had plans prepared for a $500,000 factory building at Valparaiso, Ind.

Willys-Overland Co. will re-open the Toledo plant Feb. 1 on a schedule based upon current sales.

Advertising Clubs Rap Wizard Car Advertising

NEW YORK, Jan. 18—Advertising of the Wizard Automobile Co., Charlotte, N. C., is branded as a flagrant offense against truth by the national vigilance committee of the Associated Advertising Clubs of the World, in a special bulletin issued here. The bulletin asserts that the company claimed enormous profits before a single car was produced and that a large outlay for factory and equipment was made before the design of the car was perfected.

A concern known as the Manufacturers' & Exporters' Alliance, which the Wizard company is reported to have said would take presumably 10,000 cars in 1921, was investigated by the vigilance committee and it declares it found no ground for great confidence in its financial responsibility. Charles F. Hamel, said by the vigilance committee to have been president of the Cyclomobile Co., Toledo, is declared by the committee to be sales manager of the Wizard company.

F. W. Edwardy, Sr., president of the company, is asserted by the vigilance committee to be a professional promoter with no experience in manufacturing automobiles. F. W. Edwardy, Jr., secretary and treasurer, is found by the committee to be unknown to officers of the Packard and White companies, with whom, it is asserted, he claimed previous employment.

Dodge Officers Named to Higher Positions

DETROIT, Jan. 17—While officials of the Dodge Bros. do not yet know when the plant will be re-opened, it is nevertheless expected that an announcement will be made within the next few days. It is very possible that the company will again be in production sometime during the first few days in February.

Further promotions have been made among officials of Dodge Bros. Arthur T. Waterfall, who was assistant general manager, retains this title and becomes also vice-president of the company. Harry V. Popeney has been made secretary and Reginald J. Fry assistant secretary. C. W. Matheson, who was acting general sales manager, is now made general sales manager.

The board of directors of the company is now made up as follows: Howard B. Bloomer, chairman, and Frederick J. Haynes, Arthur T. Waterfall and John Ballantyne.

Truck Line to Carry Crops to Los Angeles

NEW YORK, Jan. 17—Results of an experiment in motor transport service which is to be undertaken by the recently formed California Rapid Transit Co. on the Pacific Coast are being awaited with interest by motor truck circles. The company plans to operate a fleet of twenty Mack trucks in the Los Angeles Valley on four routes covering the entire fruit and produce belts in this territory. The trucks are to be specially built to carry fruit, vegetables, milk and merchandise of various sorts.

The routes projected are from Los Angeles to Redlands, from Los Angeles to Mecca, from Los Angeles to Alessandro and from Los Angeles to San Bernardino, with stops at all intervening towns and cities. It is expected that trucks will be in operation by July.

RAMBLER TIRE RECEIVER NAMED

NEW YORK, Jan. 19—Federal Judge Hand has appointed receivers for the Rambler Tire & Rubber Co. in a suit brought by a creditor with a claim for $3,500. The company was organized under Delaware laws in 1920 to manufacture tires and rubber goods. Its liabilities are $28,872 and its assets $60,690. It is asserted that the company is solvent but that it has no working capital and is unable to meet current obligations.

METAL MARKETS

IN some of the markets for raw, semi-finished and finished metal products the buyer is once more confronted with a dual set of prices. The disparity in prices this time is not between producer and producer. There is one market for iron and steel and most of the non-ferrous metals in which the buyer with the requisite ready cash wields the power of an autocrat. This is the market for material now ready for delivery and eating up warehouse space and interest on the value it represents. The other market is that for material which must first be produced. In the latter sellers' views as to what prices they must obtain, in order to make both ends meet, are firm as compared with the former. It was reported in the trade the other day that a sales agency offered 5000 tons of No. 2 plain foundry iron at a furnace base of below $30 a ton, without being able to find a taker. This was, by no means, "resale" iron, as that term is commonly understood. The holder was to all intents and purposes the producer who, in all probability, would have balked at booking an order for a similar tonnage at below $30, if he had to undertake production of the iron in the course of the next few weeks. It was also reported that a producer had sold 1000 tons of sheet bars at $45.50, or $1.50 a ton below the Corporation's price. Undoubtedly this "cut" price applied to a specific tonnage all ready for shipment which the producer was anxious to turn into cash. There are no indications that independents are disposed to pare the Corporation's price levels on material that must first be made. With the possible exception of lead, all non-ferrous metals can be bought cheaper for spot than for deferred maturities. In other words, there is a very pliable price for pig iron, metals and steel products that producers are now holding pending the appearance of buyers, and there is another set of prices for future production. The latter is not so easy to be budged as the former. Then, of course, there is, in addition, a certain amount of actual "resale" material in the keeping of "second hands," but the latter tonnages are comparatively light. That automotive purchasing agents are rather apathetic is to be seen from the fact that the pleas of American aluminum and alloy steel producers for higher import tariffs is not causing any haste to cover anticipated requirements at present price levels.

Pig Iron—Quotations in the trade press are far from being a guide to prices at which sizable tonnages can be obtained. Individual negotiations govern in each case. Most buying, however, is in carload lots.

Steel—A somewhat better demand for cold finished steel bars is ascribed to improvement in the automotive industries. The market for hot and cold rolled strip steel is steadying. Fresh sheet buying is of light proportions.

Aluminum—Foreign metal is still offered at 25 per cent below the reported spot price of the producer of American virgin. So far the possibility of an advance in the market through increased import duties has not engendered any buying activity.

Copper—Prediction of an 18c. market by the sales manager of a leading interest is taken no more seriously than was that made, last year, by John D. Ryan when he prophesied the return of 23c. copper. Much of the surplus is being taken off the market, however, by exports.

FINANCIAL NOTES

Fisher Body Corp. proposes to issue five shares of new common stock of no par for each share of present stock and to increase its common stock by an amount sufficient to make the exchange for Fisher Body Ohio Co. stock. The corporation will give one of its no par common shares for each common share of the Ohio company plus $2.50 in cash, provided at lease 40,000 of the 45,000 shares publicly held accept the offer. The Fisher company already owns 55 per cent of the Ohio company common stock. The corporation will then guarantee full payment on the Ohio company preferred stock by July 1. 1922, of all accumulated dividends to Jan. 1, 1921 and quarterly dividends to July 1, 1922.

Packard Motor Car Co. directors have deferred payment of the common stock dividend usually payable Feb. 1. F. R. Austin, secretary, said the company's accumulated surplus and cash position warranted payment but the deferment was decided upon in view of the disturbed business conditions.

Root & Van Dervoort Corp. has reduced its liabilities by $1,000,000 since July and for the next six months expects to eat into both inventory and floating debt in good style. The company is now devoting itself exclusively to the manufacture of automobiles.

Wire Wheel Corp. of America has notified stockholders that the payment on Jan. 1 of a 2 per cent dividend on account of its deferred dividends on preferred stocks has been postponed to conserve for the present its cash resources.

Timken-Detroit Axle Co. paid a dividend of 2 per cent on the common stock on Jan. 15. A 7 per cent cash dividend has been declared on the preferred stock, payable in quarterly instalments of 1¾ per cent each, the first on March 1.

Doss Rubber & Tube Co., Atlanta, has filed a petition requesting permission to amend its charter increasing the capital stock to $1,000,000. If granted the new issue will be in preferred stock.

Republic Motor Truck Co., Inc., for the nine months ended Sept. 30, shows total sales of $14,303,862 and gross profit of $2,989,598. Net profit for the period is $1,248,065.

United States Motor Truck Co. paid on Jan. 10 the annual 7 per cent cash dividend on preferred stock and 2½ per cent cash dividend on common.

Van Briggle Receiver Files $100,000 Action

INDIANAPOLIS, Jan. 17—Another chapter in the troubles of the various Van Briggle industries was begun Jan. 10 when William E. Reiley, receiver for the Van Briggle Mfg. Co., filed suit in the Marion Superior Court, asking damages of $100,000 in behalf of the company against L. H. Van Briggle, Ulric Z. Wiley, Henry Rominger, Frank Hilgemeier, George Weidley and Joseph Shepard, directors of the company. The company has been operating plants at Mooresville and Fowler, this State.

The suit is similar in character to the one brought several weeks ago by the receiver of the Van Briggle Motor Device Co. for damages amounting to $275,000.

The complaint charges that the company was organized without assets or without the actual sale of stock. The company was incorporated last May for $1,000,000 and shortly after that acquired the two plants above mentioned, both of which were liabilities rather than assets. The Fowler plant was assumed with an indebtedness of $30,000. The Mooresville plant, the complaint charges, was bought for more than it was worth.

Austin Seeks Funds to Finance Output

LONDON, Jan. 7—(*Special Correspondence*)—Sir Herbert Austin, chairman of the Austin Motor Co., in a circular to stockholders, explains the reasons for not paying the final preference dividend until after the stockholders annual meeting in March as a step to finance the company's output, and that deposits amounting to over $35,000,000 have been paid.

It is contemplated to issue short term (well secured) debentures, a form of financing at present in favor in Britain.

The material and supply trade doing business with the Austin company has agreed to take nearly half of the proposed issue. The other moiety will be offered to employees, stockholders and customers, and the general public.

Ford Calls Employees to Receive Bonuses

DETROIT, Jan. 17—During the first three days of this week 22,600 workers of the Ford Motor Co. are on the list to call and receive bonus checks. To-day 3,300 employees of the Highland Park plant and 5,500 usually employed at the River Rouge works. On Tuesday, 2,600 are to receive their bonus in Detroit and 5,100 in River Rouge; while for Wednesday, there are 3,700 scheduled to come to the Highland Park plant and 2,400 to the works in River Rouge. The men are being called in by groups and according to their badge numbers. All told, 52,000 of the workers of the entire Ford organization which embraces besides the Detroit and River Rouge plants, all the assembling plants in the country and in some of the foreign countries are to get bonus money. The total to be distributed will be approximately $8,000,000 it is said, and the amount per man will range from $50 to $450.

STEPHENS RESUMES FEBRUARY 1

FREEPORT, ILL., Jan. 17—Stephens Motor Co., will resume operations Feb. 1. Contracts signed with distributers of Chicago, Spokane and San Francisco, forces the resumption of operations somewhat sooner than anticipated. Starting with the New York show, the Stephens company will exhibit at twenty-one other shows from coast to coast, and, from these orders are anticipated which will insure the steady operation of the plant during the entire year. Orders so far received in 1921 are greater than during the same period of 1920 The total cars shipped in 1920 was 6,956.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Jan. 20—The large withdrawals of Government funds from local banks had no outward effect on the money market last week. The break in money rates, which had long been expected, came on Monday of last week, when call loans were made during the day at 6 per cent. The range for the week was 6 per cent to 7 per cent, as against a flat 7 per cent the week before. On Thursday the renewal rate was 6 per cent, at which rate it has since remained. A greater break came in the outside market, where call money was quoted at as low as 4 per cent on Wednesday, the lowest rate in more than a year. Time money also eased considerably. Sixty and ninety day paper and four and five months' paper were quoted at 6 per cent, while six months' paper was quoted at 5½ per cent to 6 per cent. A week earlier 7¼ per cent to 7½ per cent was quoted for sixty to ninety day paper and 7 per cent to 7¼ per cent for the longer maturities. The rates last week were the same for loans secured either by regular mixed collateral or all-industrial collateral.

The reserve position of the New York Federal Reserve Bank last week was the best since November. Total gold reserves decreased $8,524,000, and total cash reserves decreased $5,560,000. On the other hand, net deposits declined $35,645,000, total bills on hand $82,422,000, and total earning assets $67,337,000.

Total earning assets at $969,760,705 were the lowest in more than a year. Only once last year was this item reported under $1,000,000,000; on Jan. 16, 1920, is was $993,321,620. Federal Reserve notes in circulation, $800,121,480, were the lowest since last February.

Receiver Appointed for Watson Products

SYRACUSE, Jan. 19—Milton Delano, president of the State Bank of Canastota, N. Y., has been named receiver for the Watson Products Corp., manufacturers of Watson motor trucks. The appointment was made by Federal Judge George W. Ray at Norwich following a friendly equity action designed to conserve the assets of the company and is a part of a reorganization program. The new company will be known as the Watson Truck Corp. and creditors of the Products Corporation have signified their willingness to accept stock in the truck corporation in part payment of present claims.

ALLEN PRICE DOWN $200

COLUMBUS, Jan. 19—A price reduction of $200 on open models was announced to-day by the Allen Motor Co. They are reduced from $1595 to $1395. More elaborate models are to be featured, giving the choice of four colors, three styles of wheels and cord tires.

Men of the Industry

H. H. Hill has been appointed superintendent of the Petroleum Experiment Station of the United States Bureau of Mines at Bartlesville, Okla. Hill, who for the past year has been superintendent of the station, succeeds E. W. Wagy, who recently resigned to accept a position as production engineer with the Standard Oil Company of California. M. J. Kirwan, formerly State oil and gas supervisor for the California State Mining Bureau, and who recently spent a year in Japan with the Nippon Oil Company, has been detailed to the Bartlesville station to have general charge of the drilling and production work.

Fred H. Ayers, sales manager for Fisk Rubber Co., has been promoted to director of sales, in charge of the sales, advertising and publicity departments. His successor as sales manager will be William Weild, formerly assistant in this position. Leon N. Southmayd and Charles H. Gage have been made assistant sales managers. Karl S. Chamberlin, formerly assistant manager of export sales, has been made manager of this department.

L. G. Fairbanks has been made director of sales of the Firestone Tire & Rubber Co., a post heretofore held by Vice-President A. G. Partridge. Fairbanks was formerly general manager of the Firestone Steel Products Co. He has already appointed G. A. Richards in charge of all Firestone activities in Michigan; George Burkitt, manager of the Detroit branch, and P. M. Thomas, office manager of the Detroit branch.

J. W. Pickavant, of J. W. Pickavant & Co., Birmingham, England, is in the United States in the interest of the British motor, motorcycle and engineering trades. He plans to sail for home the last of this month. Pickavant says that the British motoring public has demonstrated its willingness to use American automobile accessories and that large quantities of them now are being used in that country.

Gaylord A. Hoyt and **W. N. Grounsell** have joined the sales force of the Franklin Automobile Co., Syracuse. Hoyt was with the Bell telephone system for the past twenty years and for the past twelve years had acted as district plant superintendent for the New York Telephone Co. Grounsell was for eight years with the Buick Motor Co., acting as a special representative under W. C. Durant.

H. A. Oswald, secretary and treasurer of the Hamilton Motors Co., Grand Haven, Mich., and recently factory manager, has been made acting general manager, succeeding W. G. Jarmon. Adolph Pricken, president, of New York, plans to devote a good share of his time to the management of the factory.

George T. Briggs, in charge of the automotive department of the Sinclair Oil Co., was elected president of the Motorcycle and Allied Trades at its annual meeting last week. E. H. Wetzell was elected vice-president, Arthur Davidson, treasurer, and W. H. Pearson, secretary.

Edward R. Tinker, director in the Willys companies and various other automobile corporations, has been elected president of the Chase Securities Corp., a subsidiary of the Chase National bank. He succeeds A. H. Wiggin, who becomes chairman of the board.

E. Hives, who has been for more than ten years chief of the experimental department of the Rolls-Royce British plant, is in America checking up on certain points in connection with the products of the American factory at Springfield, Mass.

Joseph E. Pogue, who has been manager of the department of economic research for Sinclair Oil Corp., has resigned from that company's service and has opened an office as consulting engineer on fuel topics at 29 Fifth Avenue, New York.

A. P. Sloan, Jr., a vice-president of the General Motors Corp. and president of the United Motors Corp., has been elected a director of the Penn Seaboard Steel Corp. Ernest du Pont also is a director of the company.

Myron T. Herrick, former ambassador to France, has been elected president of the Aero Club of America, succeeding Col. Jefferson De Mont Thompson. Herrick has been interested in aviation since the early flying days.

W. C. Chapman has resigned as export advertising manager for Hares Motors, effective Feb. 1. He formerly was with the Packard Motor Car Co. in the same capacity and has been in export work for five years.

E. A. Taylor, production engineer for the Pierce-Arrow Motor Car Co., has become general manager for the Liberty Motor Car Co. It is expected that his advent will result in several changes in the Liberty personnel.

R. W. Levenhagen, prominent in paint and varnish circles from coast to coast, through his long identification with the Sherwin-Williams Co., has joined the organization of the Glidden Co., Cleveland, O.

Arthur H. Blanchard, consulting highway and transport engineer, Ann Arbor, Mich., has been retained by the city of Colorado Springs in connection with its $1,200,000 paving program.

Fred Lampe, formerly production engineer for the Remington Typewriter Co. at Ilion, N. Y., has become superintendent of the Automatic Straight Air Brake Co. factory in New York City.

B. J. W. Kelley, formerly with Gray & Davis, Inc., has been appointed eastern representative for the American Distributing Co. He will open a New York office in the near future.

H. V. Goodenough, general manager of A. J. Miller & Co., Bellefontaine, for the past six years, has resigned to accept a similar position with the Lorraine Car Co., Richmond, Ind.

L. P. Prossen, formerly vice-president of the Nilson-Miller Co., has become connected with the Ortig Motors Co., Inc., New York, as secretary and treasurer.

A. R. Johnson, formerly of the Cadillac Motor Car Co., Detroit, has been appointed assistant sales manager of the Auburn Automobile Co., Auburn, Ind.

Henry Kissel, formerly service manager for the Splitdorf Electric Co., is now in charge of the repair department of the American Bosch Magneto Co.

Robert T. Walsh, formerly advertising manager of King, has been appointed assistant sales and advertising manager of the Apex Motor Corp.

G. W. Hoyt has severed his connection as chief engineer of the Oakes company and is preparing to enter the manufacturing business for himself.

L. G. Peed, formerly territorial man in the East for the Willys-Overland Co., has been made manager of the Toledo branch.

Joseph W. Bramwell has resigned as sales and technical engineer of the American Bronze Corp.

REEVES ON SPEAKING TOUR

NEW YORK, Jan. 18—Alfred Reeves, general manager of the National Automobile Chamber of Commerce will leave to-day for Milwaukee where he will speak to-morrow before the Wisconsin State Automobile Dealers Association. This address will be the first of the series before representatives of all branches of automotive industries. Reeves will be in Des Moines, Jan. 21, Omaha, Jan. 24, Kansas City, Jan. 25, St. Louis, Jan. 26 and 27, and Chicago, Jan. 28. He will tell the dealers and others the present situation in the industry and show them that there is no reason why they should be despondent.

VISIBLE PUMP NAMES OFFICERS

FORT WAYNE, IND., Jan. 17—At the annual election of directors held by the Visible Pump Co., the following were elected: A. Z. Polhamus, H. E. Dean, S. B. Rohrer, W. M. Roth, C. E. Shell, C. S. Fair, Allen M. Hartzell, W. H. Schnelker, Fred Wehrenburg and C. F. Koelinger. Following the election the directors met and named the following officers to serve during the ensuing year: President, A. Z. Polhamus; vice-president, H. D. Dean; treasurer, S. B. Rohrer and secretary, W. M. Roth.

WOODHOUSE VISITS AMERICA

LONDON, Jan. 5—(*Special Correspondence*)—The chairman of the S. T. D. (Sunbeam, Talbot & Darracq) motor combine told the stockholders that the combine's purchase of Jonas Woodhead & Sons, Inc., the leading leaf spring makers to the British motor industry, has shown extremely satisfactory results, and that the managing director of the company was then in America "with the object of studying improvements which American spring makers have made during the war."

JULIUS WEISS DIES

CHICAGO, Jan. 14—Julius Weiss, a pioneer in the automobile business and president of J. Weiss & Son, builders of automobile bodies and builders of one of the first automobile bodies in Chicago, died at his home here last week. He was aged 55.

T. J. KELLEHER DIES

NEWARK, N. J., Jan. 17—Thomas J. Kelleher, mechanical superintendent for the Splitdorf Electric Co., died at his home here after a brief illness following an operation. He formerly was with the Hendee Mfg. Co. at Springfield, the Remy Electric Co. at Anderson, Ind., and for 21 years with Western Electric Co.

Calendar

SHOWS

Jan. 22-27—San Francisco, Second Annual Pacific Coast Automotive Equipment Exposition, Auditorium.

Jan. 22-29—Baltimore, Annual Automobile Show, Baltimore, Automobile Dealers' Ass'n, 5th Regiment Armory, J. C. O'Brien, Mgr.

Jan. 22-29—Cleveland, Annual Passenger Car Show, Cleveland Mfr's & Dealers' Ass'n, Wigmore Coliseum.

Jan. 22-29—Montreal, Annual Automobile Show, Montreal Automobile Trade Ass'n, Motordrome Bldg.

Jan. 29-Feb. 4 — Chicago, National Passenger Car Show, Coliseum, Auspices of N.A.C.C.

Jan. 31-Feb. 5—London, Ont., National Automobile Show of Western Canada, London Chamber of Commerce, Armories, T. C. Kirby, Mgr.

Feb. 5-12—Minneapolis, Annual Automobile Show, Minneapolis Automobile Trade Ass'n.

Feb. 7-12—Columbus, National Tractor Show, Columbus Tractor & Implement Club, Ohio State Fair Grounds

Feb. 7-12—St. Louis, Annual Automobile Show, St. Louis Automobile M'f'rs & Dealers' Ass'n, Robt. E. Lee, Mgr.

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n, Armory, Arthur Fifoot, Mgr.

Feb. 12-19—Kansas City. Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, sec'y.

Feb. 21-26—Salt Lake City, Annual Automobile Show, Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Jan. 22-29 — Colombo, Ceylon Motor Show.

Feb. 7—Delhi, India, Delhi Motor Show.

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

CONVENTIONS

Feb. 2-4—Chicago, First Annual Meeting, Automotive Electric Service Assn. Hotel La Salle.

May 4-7 — Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

Rubber Association to Have Export Section

NEW YORK, Jan. 18—Directors of the Rubber Association of America, meeting here to-day, determined to go ahead at once with the formation of a foreign trade department which would seek to aid member manufacturers of tires and rubber goods in the expansion of export trading. This department was recommended at the general meeting of the association held during show week but was referred to the directors for final action.

Under the plans for the new department, an export manager will be employed and the activities gotten under way at once. These will consist of research, publicity, advisory and other work of a similar nature.

Further consideration of the program of expansion also recommended at the general meeting was held up until the next meeting in February. This additional program includes the establishment of departments of publicity, cost accounting, industrial relations, research, statistics and technical and standardization.

GILBERT & BARKER BUILD

SPRINGFIELD, MASS., Jan. 17—Several large additions to the plant of Gilbert & Barker Mfg. Co., this city, are being hurried to completion in anticipation of an early return to normal manufacturing conditions. The new units are a foundry, 400 x 100 ft.; three-story manufacturing building, 240 x 60 ft.; sheet metal department addition, 180 x 160 ft.; storage building addition, 40ft.; addition of two turbine units to power plant. Nearly a whole city block has been bought adjoining the present factory site to allow for future expansion. The company manufactures gasoline filling stations, lubricatig oil storage and distribution systems for factories, and heat treating furnaces for the metal trades.

Mexican Trade Good; Sales on Gold Basis

SAN ANTONIO, TEX., Jan. 17—According to Ralph Trejo, general sales manager for the Triangle Sales Co., who has just arrived here from a six weeks' sales trip through Mexico, business conditions in that country have been especially good recently, so far as selling automobiles and accessories are concerned.

"Automobile Row in the City of Mexico is a most interesting highway," said Trejo. "All sales are for cash and almost all is gold, very little silver being in circulation, and no currency. The accessories flank the automobile shops proper, and are a vital part of the business. French and English cars, in very high-priced models, are sharp competitors with American-made machines, but in the medium-priced and cheap cars the American has practically no competition."

U. S. C. C. SETS CONVENTION

WASHINGTON, Jan. 15—Selection of Atlantic City as the meeting place of the Chamber of Commerce of the United States was announced here to-day. The ninth annual convention will be held April 27, 28 and 29. The representatives of American business will assemble in an effort to shape a definite program of co-operation.

Belgium to Continue December Exhibits

PARIS, Jan. 5—(*Special Correspondence*)—Belgium has fixed on the period Dec. 3 to 15 for her next automobile show which, like previous events, will be held in the Cinquantenaire Palace, Brussels. This show will be open to the entire automotive industry and will be international. In order to eliminate rival events, it has been decided that no automobile exhibits shall be allowed at the Brussels Trade Fair, to be held during the summer. Firms taking part in this will be refused admission in the Brussels, London and Paris automobile shows. Belgian automobile manufacturers have also decided to boycott the motorcycle and bicycle show announced for next March in Brussels.

The European show program is now complete, the series opening with the Paris exhibition in the Grand Palais on Oct. 5 to 16. London will hold two shows, the first one being devoted to trucks on Oct. 14 to 22, and the second one for passenger cars being held from Nov. 4 to 12 inclusive. Belgium closes the series with Dec. 3 to 15. It is not known if Milan will have a show, and a motor exhibition in Berlin next winter is doubtful.

NASH TO ADDRESS N. A. D. A.

ST. LOUIS, Jan. 15—The annual master address at the convention of the National Automobile Dealers Association will be made by Charles W. Nash, president of the Nash Motor Co. The convention is scheduled for Chicago during National Show Week there and it will sound the "Back to Selling" war cry of the association to 35,000 members.

AUTOMOTIVE INDUSTRIES
The AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, JANUARY 27, 1921 NO. 4

Cost Accounting as a Basis for Selling Cars

On the competitive market that is before the vehicle manufacturer, the car that supplies the best value for the money will win. It behooves the maker to know the cost, in order to intelligently meet competition. This article explains one method.

By Clyde Jennings

HOW much does the vehicle you are building cost?

How much does each part cost?

Are you building these parts cheaper than you could buy them?

Is your direct charge for direct labor, indirect labor, factory maintenance or sales too high?

Can you discuss these items with your neighbor and if you do, will you use the same words with the same meaning?

These are a few questions that were suggested at a recent meeting of the Industrial Cost Association. The object of this meeting was to organize in New York a section of the association. The section was organized and will hold monthly meetings. At these meetings the members have promised that they will sit around the table and discuss costs. First, they will establish definitions for the various terms so that they can understand each other.

The men gathered at this meeting were very frank about present conditions. They freely admitted that following the free sales period of the past few years they were now confronting a falling market. Cost has gained a greater importance than ever before. Competition is certain to be sharp and many factories will need to know exactly where the high spots in the cost are. They will need to get down to bed rock so that they can sell as low as possible and yet not lose money. They will also need to analyze their costs and compare them with other factories doing similar work to be sure that these costs are within reason.

To do this, it is necessary to have a recognized terminology, so that the confréres may speak the same language.

Prof. W. Rautenstrauch of Columbia University, who also is a practical and active manufacturer, talked for some time on this line of thought. He said that in his work he often felt the need of discussing the cost of "tools per man" with factory managers who are doing a similar work to that done in his factory. This need not mean a similar product, but working with similar materials. In such cases most of the time of the discussion is apt to be taken up with reaching an understanding as to how depreciation is charged off and what items are included in certain other charges.

The speaker cited the advance made in the study of chemistry since all chemists spoke the same lan-

guage and used the same measurements. He also cited the recent accomplishments of the astronomers in measuring the star Betelguese with its hundreds of millions of miles in computations. The thing that we need to do now, he said, is to establish standards whereby we can accurately measure some of the factors in our everyday affairs.

The story of the organization of this Association is interesting. A. A. Alles, Jr., as a member of the cost committee of the American Gear Makers' Association, attempted to gather material for a paper to read before that body. He wrote to practically all of the industrial associations and to many large manufacturers for assistance, but the replies that came back were requests for assistance from him. He found that while many industrial associations had attempted to establish systems, most of them had not been able to make much progress, because they had confined themselves to the distribution of forms rather than to the extension of their work to explain why such a system was recommended. One or two associations had made definite progress, but they had confined their work exclusively to their lines of business and had not really attempted a solution of the great fundamental problems.

It occurred to Alles while working with this problem that cost accounting education should not be limited to a definite industry, but that its fundamentals should be the same for all industry. As a result of this correspondence it became apparent that there is great need of co-operation on the part of practical business men in seeking a solution of this question. So this organization was formed by representatives of firms who asked permission to co-operate in the dissemination of this information. This movement, Alles explained in telling the story to the New York section, is entirely apart from any similarly named movement on the part of professional accountants. Regardless of the merits of accounting systems, this body of men are looking at the problem differently. They have nothing to sell and they will get benefit only as they join in the mutual understanding and practices of other manufacturers, so that they can discuss costs with their neighbors. Any direct value will have to come to them through the elimination of that competition which is founded on a lack of understanding. The membership in the association does not bind the firm or trade association to an adoption of the methods suggested.

The prospectus of the Association says, "It is not a matter of regulating costs or prices. That would be contrary to public policy." This prospectus says the objects of the association are:

(a) To stimulate the interest of all manufacturers in correctly determined costs.

(b) To standardize cost and accounting terminology; to establish governing principles; and to simplify cost accounting.

(c) To educate our members in the use and advantages of graphic charts and other modern methods of cost analysis and control.

(d) To assist members of the Association who are identified with cost committees of trade organizations in formulating uniform cost methods, and to recommend to our members the adoption of such uniform methods.

(e) To provide a forum for the discussion of cost problems and practices through general and local meetings; and to gather and disseminate news of interest to our members.

(f) To establish a library of cost literature, and to maintain a bureau of information through which members may be assisted in the solution of their individual cost problems.

(g) To co-ordinate the efforts of our members to the end that cost production may be considered in its proper relation to the complex problems of industrial management.

The method of carrying out these objects is simple. It is the intent to arrange the national membership into groups and that these men shall meet and discuss definite topics. One evening might be devoted to "direct labor." Another to what it is proper to charge to the sales department. A transcript will be made of these discussions. They will be sent to the central body committees and there digested. It is hoped in this way to finally arrive at a satisfactory definition of the terms that now figure in costs and which are now so variable.

One of the speakers at the recent New York section meeting was C. H. Smith, who is in charge of clerical work for the Westinghouse Air Brake Co. He said that his company had joined this association because it had been unable to solve its own problems and wanted assistance from all sources. He said that when the effort was first made to learn what were the costs of manufacture of that company's products, only confusion resulted. Each of the factories had its own method of figuring cost and the gathering of data on labor, sales and other items were useless because they could not be compared. Patient effort had brought some order out of this confusion, but the desired results were still far in the future. Smith told an interesting story of a recent conference on this subject, at which one of the confrères was a professor of cost accounting for a correspondence school. This man said that the proper method of charging overtime was to divide it equally between the factory maintenance charge and the sales charge. His reason for placing the charge against the sales department was that if the sales department had not sold the goods, the overtime would not be incurred.

All through these talks was a running comment on the difficulties that manufacturers have recently experienced in solving the questions of federal taxes and of the estimating of depreciation to obtain the proper credits in making tax returns. The present confusion, it was maintained, is due to the fact that there is no existing standard or understanding which the government can adopt for the making of these returns. Such an understanding, it was asserted, would have saved the manufacturers a great deal of expense and confusion.

The membership of this Association is quite large, considering that it is less than a year old. The roster of firms and trade associations is an imposing one. It apparently does not include any automobile manufacturer, but it does include many parts manufacturers.

The lesson for the automotive industry that is to be drawn out of the work would seem to be this:

The selling of automotive vehicles is to be strictly competitive for some time in the future. In the end, the man who gives the best value for the money will win. The best method of making sure to give the best value for the money is to know exactly the cost.

Profitable selling, of course, means getting back the cost with a reasonable profit. So cost must become the basis of selling. Cost can be separated into its several elements and the manufacturer who cannot meet the prices of his competitors can then pick out the points of excessive cost. Without adequate cost data, the manufacturer does not know where to cut, for he does not know in what regard his costs are too high.

A. A. Alles, Jr., 1501 Peoples Bank Building, Pittsburgh, is executive secretary of the Association. F. G. Roberts of SKF Industries, 165 Broadway, is secretary of the New York section.

Friction Metal for Brake Linings

An adaptation of European practice facilitated by manufacture in this country of a copper-lead alloy said to possess exceptional friction qualities. Tests with V-shape brake on truck promise well. Elimination of brake squeaking said to be effected. High friction coefficient claimed.

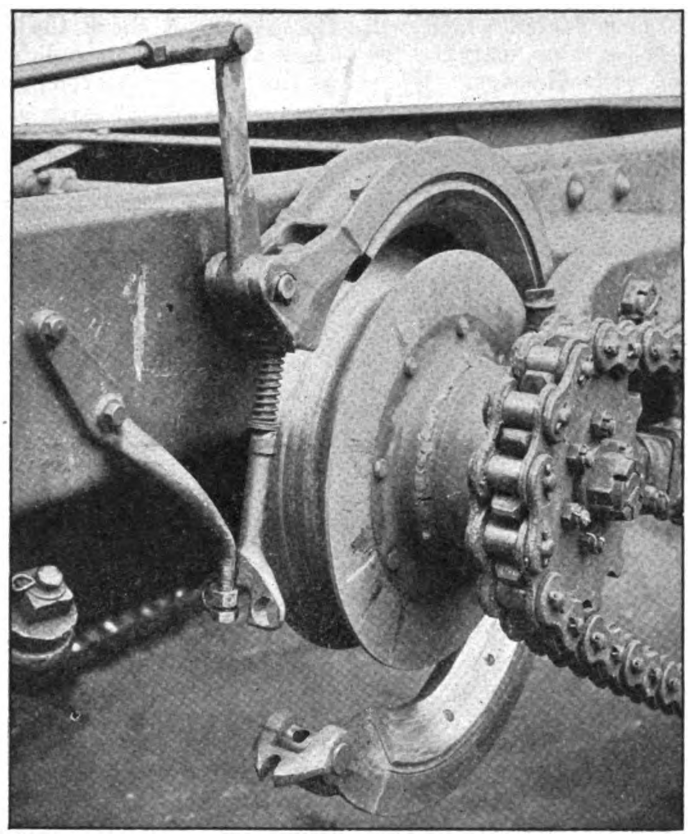
IN the United States and Great Britain it is now the almost universal practice to line motor car brakes with a woven friction lining of asbestos, cotton, rubber and wire. In Continental Europe, on the other hand, metal to metal brakes are extensively used, and, of course, all railroad braking is by metal to metal brakes. One objection to metal brakes for motor car work in the past has been that such brakes lose a great deal in holding ability when oil gets onto their braking surfaces. It is quite possible that with improved methods for packing the axles, so as to prevent the escape of oil from them, this objection is no longer valid.

The Super-Refined Metals Co., manufacturers of the well-known Kelly metal for bearings, have developed a copper-lead alloy called Kelmet which has exceptional friction qualities and which they plan to market as a brake metal. It was found that lining an ordinary brake shoe or sector having a flat cylindrical friction surface with the metal, did not work out to the best advantage, as the brake then was too harsh in action. Consequently a brake with V-section surface was designed, and this is said to have overcome the harshness.

The manufacturer of this metal made some tests with these brakes on a Mack truck at Los Angeles. These tests attracted the attention of the International Motor Co., manufacturers of the Mack truck, and at their invitation officials of the metals company came to New York recently and had a set of their brakes fitted to a Mack 5½-ton truck with which braking tests were made. The total weight of truck and load was 21,845 lb. The first test was made on a hard surfaced road in New York City which is mainly used for trucking purposes in unloading ships. The road consists mostly of sand and gravel but has a subtantial foundation and is very good. The results of these trials were as follows:

Speed, M.P.H.	Distance,* Ft.	Time, Sec.
15	23 2/3	2 1/5
14	17	1 4/5

*Traveled after brake was applied.



V-type brake with metallic friction surface applied to Mack truck

The second test was made on Fort George Hill, which has a roadbed of stone blocks and a grade of 12 per cent. The results of this test were as follows:

Speed, M.P.H.	Distance, Ft.	Time, Sec.
20	96 1/6	5 2/5
20	86 1/4	4 3/5

These tests were under the supervision of the Mack company testers and several officers of the Super-Refined Metals Co., including G. H. Beaton, president; F. C. Harding, vice-president, and H. A. Walker, who devised the method of application of the Kelly metal with the V-type of brake.

The Mack company on Oct. 26 held a similar test with the same truck equipped with its standard fabric lined brakes. The results of these tests on the level roads were as follows:

Speed, M.P.H.	Distance, Ft.
12	20 11/12
12	20 11/12
12	20 1/4

The tester then made a first adjustment of the brakes, after which he made two more trials as follows:

Speed, M.P.H.	Distance, Ft.
12	32 1/4
12	24 1/4

On the Fort George Hill only one trial was made, with the following results:

Speed, M.P.H.	Distance, Ft.
15	56 1/3

Reducing all the tests held under the same conditions to a common basis of 12 m.p.h., the average stopping distance on the level with Kelmet brakes was 13 5/16 ft., and with fabric brakes 24½ ft.

Reducing the Fort George Hill results to a basis of 15 m.p.h., the truck with the Kelmet brakes stopped in 56⅓ ft. and the truck with the fabric brakes in 51¼ ft. These test results therefore do not appear very consistent, for while in the tests on the level the truck was stopped with Kelmet brakes in little over half the distance as with fabric brakes, on the 12 per cent down grade the relative distance covered before coming to a stop was only slightly less than with the fabric brakes.

The alloy used for brake lining has a melting temperature of 1650 deg. Fahr. and is claimed to have a friction coefficient roughly 22 per cent greater than asbestos fabric.

New Wright Aeronautic Engine Succeeds the Hispano-Suiza

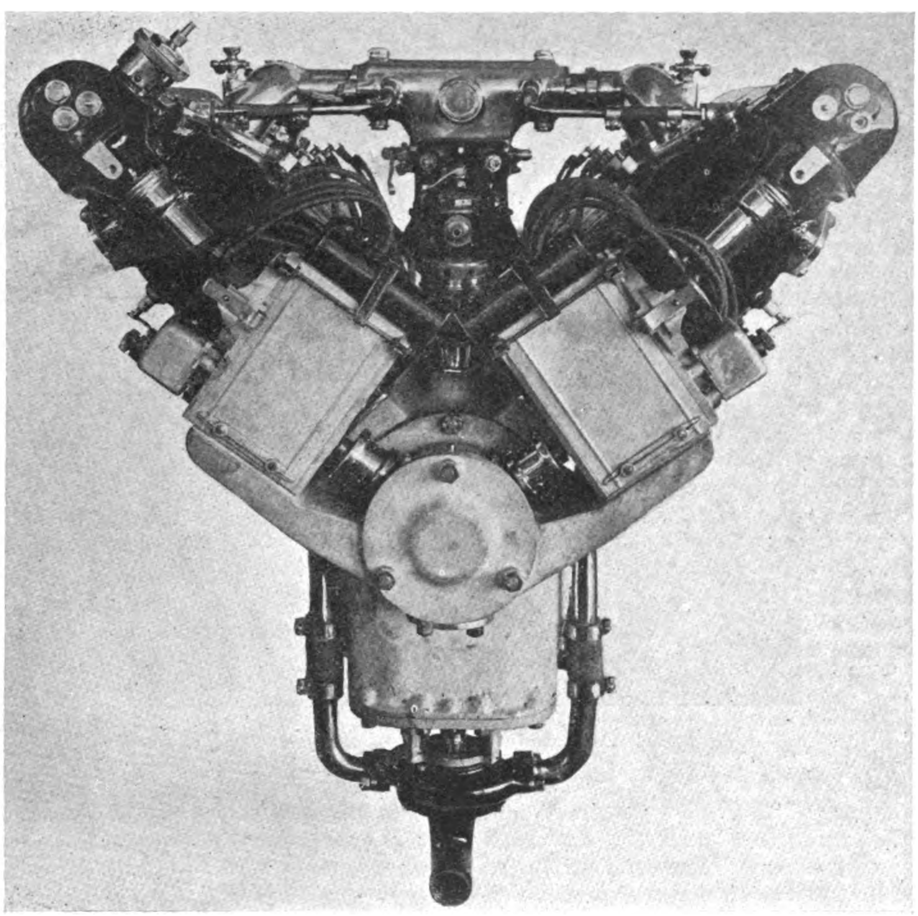
New job resembles predecessor in many detail parts, retaining steel sleeve and combination valve stem and tappet, but embodies many changes originally developed by Wright company, including better cooling and simplified lubrication systems. New magneto mounting provided.

By A. Ludlow Clayden

THE Wright Aeronautical Corp., the successor of Wright-Martin Aircraft Co., who manufactured Hispano-Suiza motors in large quantities during the war, have just produced a new engine which will be known as the Wright model E-2, this marking the abandonment of the connection with Hispano. While the new engine embodies many features which are similar to Hispano practice there is scarcely a detail that is not an original development of the Wright Aeronautical company's engineering work. In fact the new model resembles the original Hispano only to about the same extent as the Liberty engine resembled the original Mercedes.

There are two typical Hispano features retained, namely, the cylinder construction, which consists of steel sleeves threaded into a common aluminum water jacket, and the well known combination valve tappet and valve stem. Even in these parts there are changes, notably in the heads of the steel cylinders, which are very much thicker, a change which has been found to do away almost entirely with valve warping. Probably the thick cylinder head remains actually cooler in operation than a thin head, in just the same way that a thick piston head has been found to enable a piston to run cooler.

Better valve cooling has been still further insured by altering the shape of the exhaust valve ports. These are oval in normal section, giving a large area with but small depth, so that there is plenty of room for water beneath the ports and above the cylinder heads. Tests on the block and in the air indicate that the valve life has been at least doubled as compared with the Hispano original design.

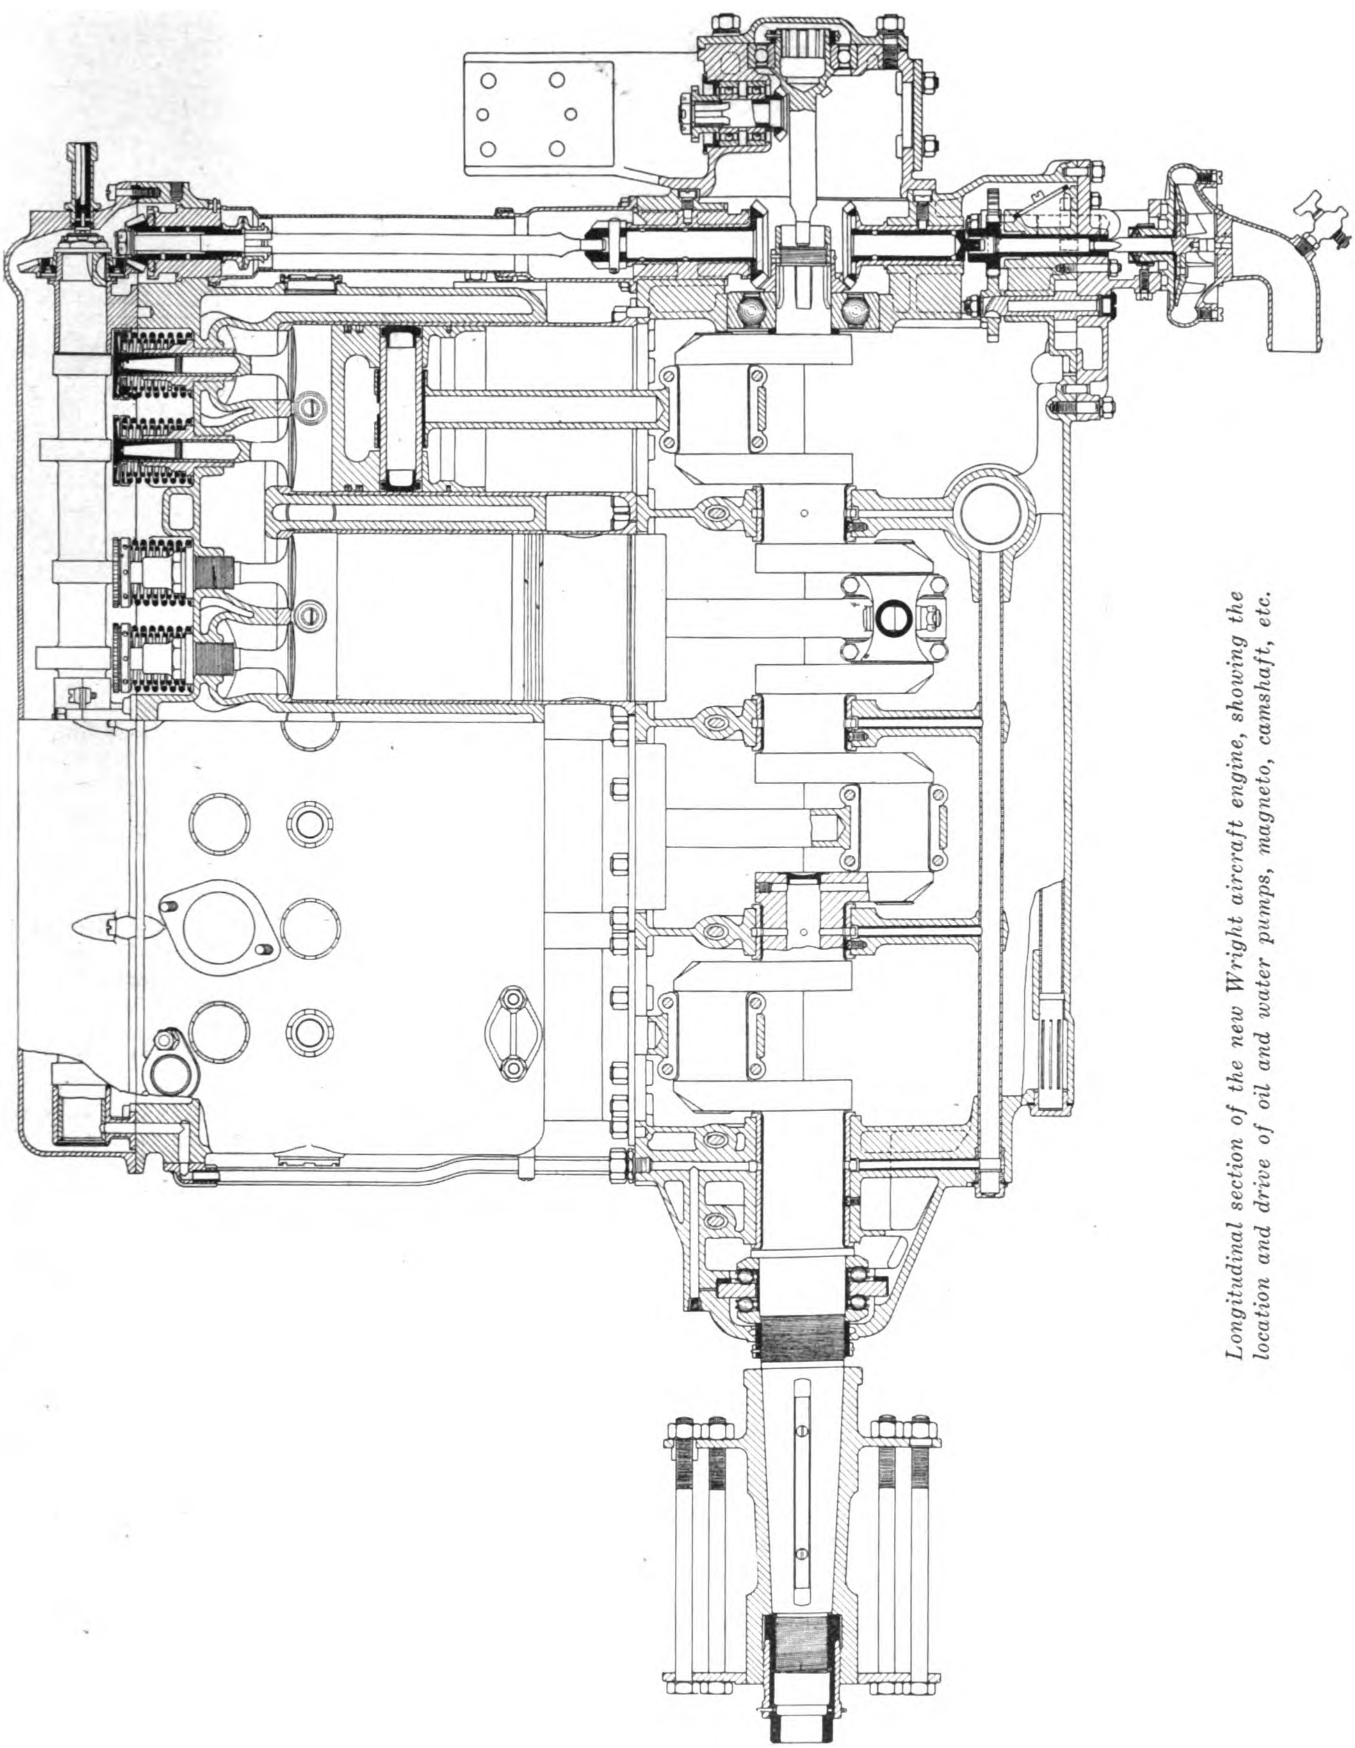


Rear view of Wright aeronautic engine, showing new inclined mounting of magnetos

A deeper water jacket is used, coming low enough to cover all the piston rings at the bottom end of the stroke. This provides enough extra piston cooling to allow a slight increase in compression with corresponding increase in power. The change in compression is not great but just enough to be perceptible, the depth of the combustion space having been decreased by 5 mm. by the thicker cylinder heads.

The pistons have no webs beneath the heads and are generally similar to the 300-hp. design, but the four rings have individual grooves and there is a change in the piston pins. On the 300-hp. pistons the pins floated and were held endwise by fixed aluminum plugs like the Liberty design. The piston pins used in the new engine also float, but cylinder scoring is prevented by bronze plugs pressed into each end of the pin. This considerably simplifies the piston machining and is equally effective.

Perhaps it is in the lubrication system that the Wright



Longitudinal section of the new Wright aircraft engine, showing the location and drive of oil and water pumps, magneto, camshaft, etc.

engines have departed furthest from Hispano practice. It may be remembered that the Hispano motors had vane pumps for the pressure side and gear pump mounted on the extreme rear end, behind the magnetos, sucked oil from the crankcase and delivered it to the tank.

While perfectly effective, this design had three drawbacks. Firstly, the vane type of pump requires delicate fitting in the first place and is subject to loss of efficiency by wear. Secondly, the single suction pump having only one crankcase connection, needed a case with a deep sump. Thirdly, the separation of the two pumps called for rather a lot of external piping.

This design was first departed from in the Wright 300 hp. by the substitution of a single assembly of three gear pumps in the crankcase. The Wright E-2 has carried still further the elimination of connections, while the completeness of the distribution of oil has been improved.

As for the 300 hp., there is a single assembly of two suction and one pressure pump. This group of pumps is mounted on a base plate which mates with a surface on the bottom of the shallow crankcase. The main pressure line is internal, and so is the suction line which goes to the front end of the case. The ends of these two lines are brought to holes in the crankcase base, which holes register with ports in the base plate of the pump so that there are only two external connections to be made, one the delivery from the engine to the oil tank and radiator, the other the intake from the tank to the pressure pump.

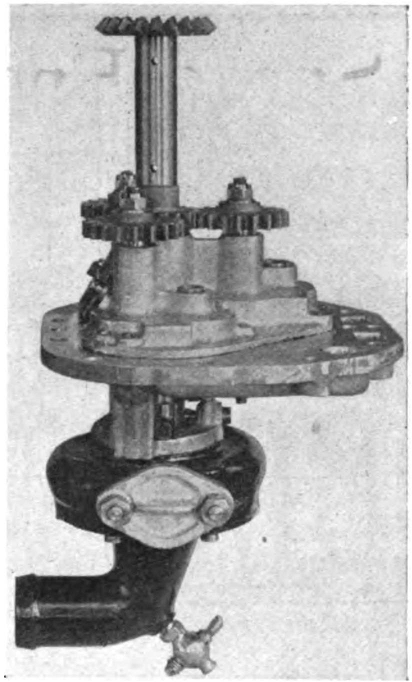
Oil is supplied in the first place to grooves in the bearing bosses of the crankcase which encircle the bushings, through the crankshaft to the connecting rods, and thence by spray to the other crankcase parts. From the front main bearing a lead goes to each of the front camshaft bearings, thence the oil flows through the camshafts, and out through holes which are drilled in the approach face of each cam, as well as through others leading to the center and rear end camshaft bearings.

In the original Hispano, excess oil from the camshafts found its way back to the base through the hollow vertical shaft which drives each camshaft from its rear end. This successfully disposed of excess during climbing, but when flying on an even keel or diving there was always a possibility of sufficient oil collecting to rise over the tops of the valve guides, with consequent fouling. To overcome this, the new engine has a return lead at the front end of each block of cylinders as well as holes around the vertical shaft bearing at the rear end.

Another improvement in lubrication is the taking of a separate pressure lead from the main channel to the ball thrust bearing, it being believed that lack of adequate oil has sometimes caused this bearing to drag and so rotate a little in the crankcase.

Another feature of conspicuous advantage is found in the magneto mounting. The old design used two magnetos which were set in a horizontal plane on a transverse bracket bolted to the rear end of the crankcase, the drive being from the end of the crankshaft through a slot and tongue to a smaller shaft bearing a spiral gear, and thence to a cross shaft with a magneto coupling on each end. This construction called for one right hand and one left hand magneto and also had the disadvantage that the magneto bracket came in such a position that the bed timbers of fuselage could not be extended rearward.

In Model E-2 the magnetos are set at an angle to each other, which lifts them out of the way of the fuselage members. Also, instead of the single transverse shaft the bracket carries two short shafts each provided with a bevel pinion the two meshing with a single bevel which takes the place of the spiral gear. This makes the rotation of the magnetos both alike and so simplifies the handling of spares.



The three oil pumps grouped in a single assembly fitting into the crankcase, with water pump below and outside the crankcase

Positive clutch used in camshaft drive to enable fine angular adjustment in timing valves

Mentioning spare parts, it has been an object in laying out the new model to use as many as possible of the details of the 180 hp. engine, which was made in large numbers by the Wright-Martin Corp. and for which there are still fair stocks of spares in various places. Thus the marine type connecting rods which were the first American innovation and the first departure from Hispano practice are retained unaltered. The crankshaft and camshafts are identical, the water pump is the same, although it attaches to a quite different type of oil pump, and so on throughout the smaller parts.

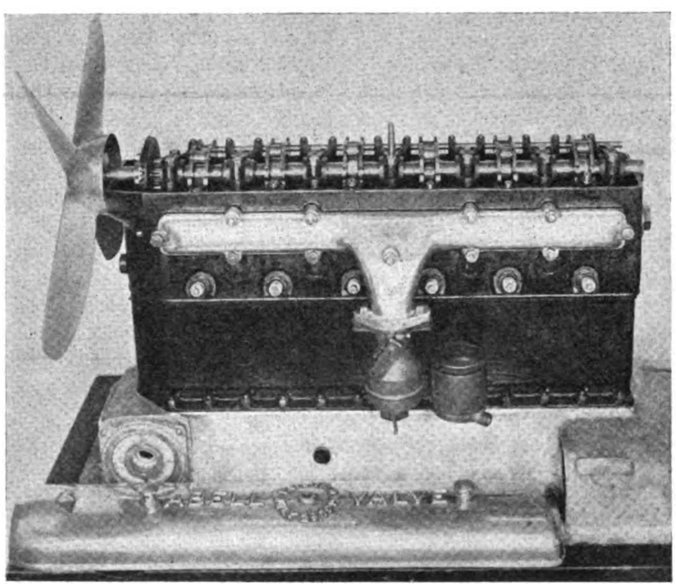
WHILE it is important to maintain a low-pouring temperature for casting aluminum alloys, it is equally important to avoid overheating the metal in the furnace charges. Doubtless some advantage is gained when overheated melts are allowed to cool to the correct pouring temperature, and part of the danger of overheating is minimized by so doing. Nevertheless, for aluminum, overheating is very objectionable, because of the rate of dissolution of iron from cast iron melting pots and of the reduction of silica from clay crucibles, as well as absorption of gases from the local atmosphere. For molten metals, the absorption of gases increases with rising temperature, this being possibly due to the fact that metals form loose compounds with hydrogen and nitrogen. The absorbed gases are often held by the metal until solidification starts, when they are liberated and cause unsoundness. Hence, an overheated melt would contain more absorbed gases than one not overheated, and it would be expected that castings poured from former would be more unsound than those poured from latter.

IT has been the experience of the R. A. F. in Palestine and Mesopotamia, where atmospheric temperatures are generally quite high, that water-cooled engines almost invariably boil their water away, whereas air-cooled engines continue to work. The explanation offered is that an air-cooled engine will continue to function at higher temperature than that at which water boils away.

A High Speed Engine With Positively Operated Valves

But one poppet valve per cylinder is used, this being put in communication alternately with inlet and exhaust ports by a rotary distributor placed lengthwise of cylinder head casting. Yoked rocker levers have two rollers in contact with opposite sides of cam. Cooling of valves by incoming charge makes it possible to use higher compression without knock.

WHILE the ordinary spring-returned poppet valve works satisfactorily at low speed, difficulties are encountered at extremely high speeds which are used in racing engines and some stock engines. Naturally, the higher the speed of the engine the stronger the spring must be to keep the cam follower in contact with the cam, and the stronger the spring the greater the strain on the valve and usually also on the material of the spring itself. The difficulty usually lies either in noisy operation or in excessive strain on the valve mechanism at high speed. Moreover, the speed at which the engine gives its maximum output is dependent upon the ability of the valve and valve follower to follow the cam outline.



Abell engine, showing crankshaft, double roller rocker arms and neat inlet manifold

In racing engines mechanically opened and closed valves have been used repeatedly in the past. The problem of designing a poppet valve mechanically operated both in opening and closing involves considerable difficulty, for whereas the pressure within the cylinder during the compression and power strokes takes up any slackness there may be in the valve mechanism and moves the valve toward its seat, if it is not already there, the suction in the cylinder during the inlet stroke tends to raise the valve off its seat and to allow spent gases to be drawn back into the engine if there is any slackness in the mechanism. And it is, of course, impossible to eliminate all play and flexibility from a valve operating mechanism consisting of several very light parts.

In a design of engine due to R. Abell, and which is illustrated herewith in cross section and longitudinal elevation partly in section, only a single poppet valve is used per cylinder. This valve serves for both the inlet and exhaust. The function of the valve is determined by a rotary distributor which places the poppet valve pocket in communication alternately with inlet and exhaust ports.

The engine is a six cylinder block cast type of 3¼ in. bore x 5 in. stroke. Both the poppet valve and the distributor are mounted in the cylinder head, which is detachable and is bolted to the cylinder block with the usual copper-asbestos gasket between. The combustion chambers, which are located in the cylinder head, are hemispherical in shape and are completely machined. Two spark plug bosses are provided, on opposite sides of the cylinder head. The overhead camshaft is located in the center plane of the cylinders and is operated from the crankshaft through a vertical shaft at the forward end of the engine which is provided with bevel gears both at top and bottom. This vertical shaft is a high speed shaft, being geared up from the crankshaft in the ratio of 3 to 4, and can therefore be quite light. It is enclosed in a "V" shaped extension at the forward end of the cylinder casting and is provided with a splined sliding joint to make allowance for the heat expansion of the cylinder block.

The valve rocker levers are yoke shaped and are provided with rollers on opposite sides of the cams. The cams are of unusual shape and they completely fill up the space between the rollers throughout the cycle. There is, therefore, no lost motion in the whole mechanism at any point of the cycle, and the valve must absolutely follow the outline of the cam. The rocker levers are mounted on a hollow shaft which is carried by the caps on the camshaft bearings, and after removing the nuts from the studs of the bearings, the entire valve mechanism, including the camshaft, can be removed from the engine. The poppet valve, which is bowl shaped for lightness and ease of opening and closing, has a clear diameter of 1 13/16 in. and a lift of 7/16 in. The seating of the valve can be adjusted by means of a spool which is locked in place by a castellated nut and cotter pin. In adjusting the valve, it is brought to within a few thousandths of an inch of its seat, and the inertia on the valve and the compression pressure can be relied upon to close it. The poppet valve begins to open 45 deg. before the end of the power stroke and closes 45 deg. from the beginning of the compression stroke, thus remaining open for a period corresponding to a crank motion of 450 deg. When the crank is in the top dead center position at the end of the exhaust stroke the distributor is in its central position, both the inlet

and the exhaust port being closed. Consequently, the exhaust port closes and the inlet valve port opens simultaneously irrespective of speed.

The compression chamber is so dimensioned that a cold compression of 90 lb. is obtained, and with this compression there is said to be absolutely no knocking with the ordinary commercial gasoline. This is ascribed to the fact that there is no overheated exhaust valve with which the combustible gases come in contact and become ignited. After each exhaust stroke the incoming cool charge passes over the exhaust valve and cools it to such a degree that it never reaches a temperature beyond that corresponding to the bluing temperature of steel. It is claimed that, owing to the thorough cooling of the valve, it is possible to use a compression 20 lb. higher than is ordinarily employed. This results in a higher explosion pressure, increased power and reduced fuel consumption. Owing to the fact that the poppet valve has no spring and its spool is quite free on the end of the rocker lever, the valve continuously creeps around on its seat, which results in uniform temperature conditions and uniform wear over the whole valve head and prevents pitting and other valve troubles. Since the valves are not held down to their seats by springs and remain open throughout the exhaust and inlet strokes, the energy consumed in operating the camshaft is considerably reduced.

The distributor valve is made of cast iron and is cored out for lightness. To facilitate machining and foundry work it is made in halves, with a tongue and grove joint at the center.

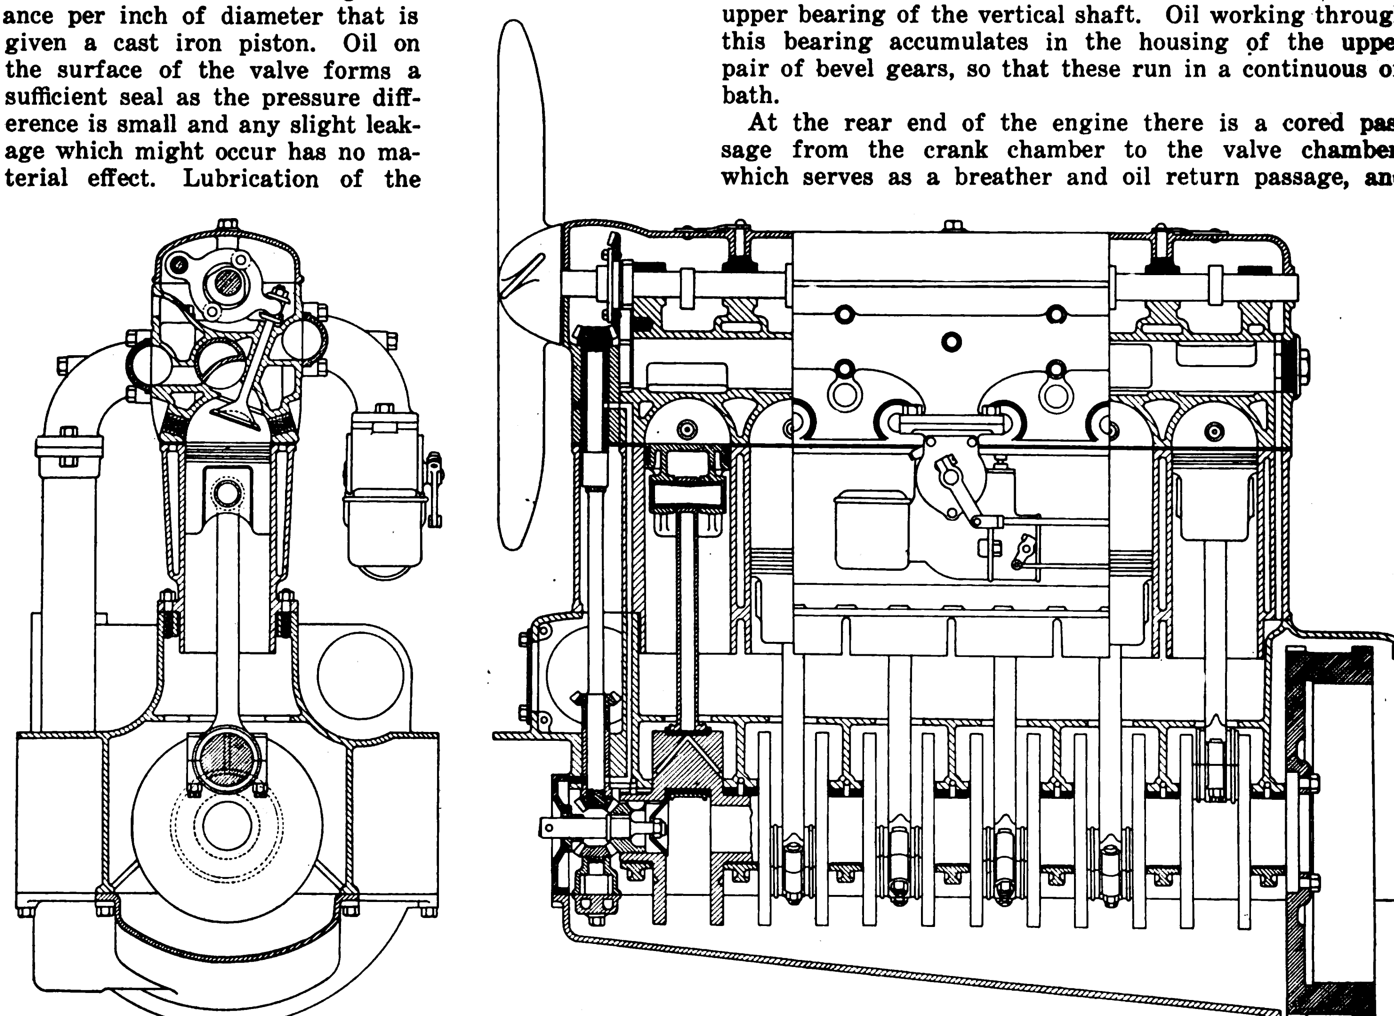
The distributor valve is given about the same clearance per inch of diameter that is given a cast iron piston. Oil on the surface of the valve forms a sufficient seal as the pressure difference is small and any slight leakage which might occur has no material effect. Lubrication of the distributor valve is effected entirely by oil spray in the exhaust. Additional lubrication has been provided in some experimental engines, but was found to be superfluous, ample lubrication being provided by oil deposited by the exhaust gas. The temperature of the distributor valve is not high, due to the cooling effect of the charge which absorbs heat left by the exhaust gases.

One advantage of the construction employed is the fact that the incoming charge passes over surfaces of the distributor and poppet valves which have just been heated by the exhaust. This results in vaporizing the fuel and provides in effect the same hot-spot which in engines of the conventional type is arranged in a quite different manner.

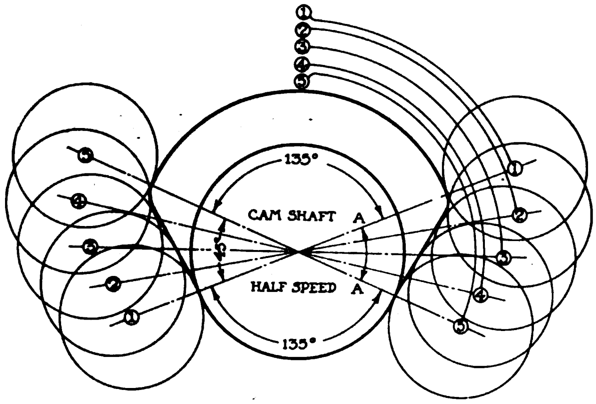
The large bevel gear at the forward end of the camshaft is made of bakelite in order to secure noiseless operation. This gear has 40 teeth, while the crankshaft pinion has 20.

Lubrication of the engine is by the pressure system from a gear pump mounted below the crankshaft ahead of the forward main bearing and driven by a bevel gear from the crankshaft bevel pinion. The crankshaft is supported in seven bearings. The main journals are 2½ in. diameter, and the crank cheeks or webs are in the form of complete disks. Oil from the pump is delivered directly to each main bearing and thence finds its way through circular grooves on the crank disks and drill holes in the crank cheeks and crankpins to the crankpin bearings. A vertical oil passage is drilled in the forward wall of the crank chamber and the cylinder block. Through this oil is forced to the upper bearing of the vertical shaft. Oil working through this bearing accumulates in the housing of the upper pair of bevel gears, so that these run in a continuous oil bath.

At the rear end of the engine there is a cored passage from the crank chamber to the valve chamber, which serves as a breather and oil return passage, and



Transverse and longitudinal sections of Abell engine, showing positively operated poppet valve and rotary distributor valve



Layout of cam used on Abell engine

insures that the valve mechanism operates in an oil mist.

The valve mechanism is protected by a cast aluminum cover. Both parts of the crank chamber are also of aluminum, and the weight of the complete engine without starter and generator is only 360 lb. The cylinder barrels extend some distance into the crankcase, and baffle plates are provided in the upper half of the crankcase to prevent over-oiling and cylinder carbonization. The pistons are cast of aluminum and are of the slipper type. Each piston is provided with three rings at the upper end. The connecting rods are tubular, 10 in. long and of 13/16 in. outside diameter. The hollow piston pin has an outside diameter of 1 in.

In view of the fact that the engine is designed for operation at high speed, an attempt was made to reduce to a minimum the weight of reciprocating parts. The total weight of the piston, rings, piston pin, connecting rod, cap and bolts is only 2½ lb.

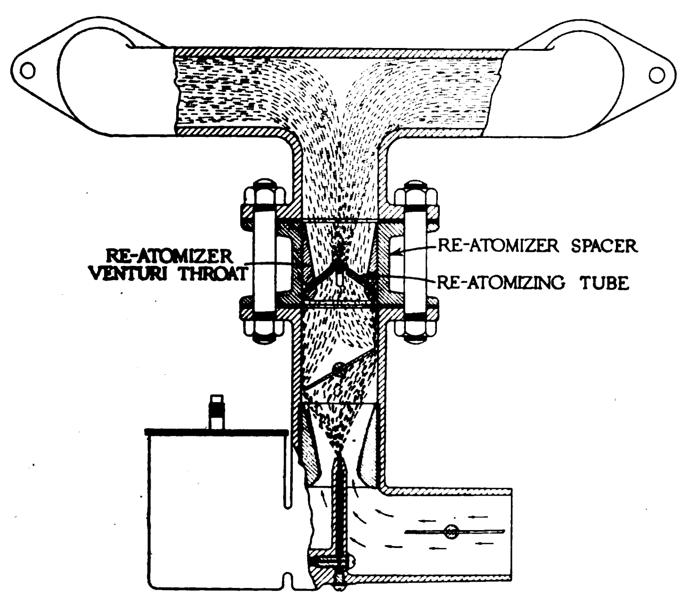
This engine is expected to develop its maximum power at 4000 r.p.m. and to show a straight horsepower line up to 3000-3200 r.p.m. It is expected to obtain 30, 60 and 90 hp. at 1000, 2000 and 3000 r.p.m., respectively, this estimate being based upon the performance of previous designs.

One of the features of the Abell engine is the arrangement of the manifolds. These are formed one-half in the cylinder head casting and one-half in the manifold castings. Each half of the gas passage being of semi-cylindrical form, these passages can be ground and polished, so there will be no obstruction to which unvaporized fuel particles can adhere. A baffle plate is cast into each manifold between the third and fourth cylinders, so that there can be no interference between the front and rear cylinders. The firing order is 1-5-3-6-2-4. A 1½-in. carbureter is fitted. The radiator fan is secured directly to the front end of the camshaft and no separate fan drive is required. The fan is four-bladed, is cast aluminum and is provided with a friction clutch to take care of sudden acceleration and deceleration of the engine.

A Re-atomizing Device

THE carbureter department of the Penberthy Injector Co. announces the Ball & Ball re-atomizer, a device recently invented by F. O. Ball, which is placed between the carbureter and the manifold. It comprises a spacer into which is pressed a venturi throat carrying four small tubes. The spacer contains a passageway of the same diameter as the intake manifold.

The grade of gasoline sold to-day is extremely difficult to vaporize completely, and even when the vapor has been made it is easily condensed by striking obstacles to its free passage. The butterfly valve used in all carbureters, when only partly opened presents such an obstacle. As the vapor strikes this butterfly valve, the larger portion of it is condensed and thrown against one wall of the carbureter and some passes up the wall of the manifold in a liquid form and cannot be equally divided between the various cylinders.



Sectional view of re-atomizer

Around the lower outside edge of the re-atomizer is a groove or annulus which forms a small circular chamber between the inside or the spacer and the outside of the re-atomizer. The ejector effect of air flowing by a tube extending into the air stream in the direction of flow of the air is very well known. This principle is the basic idea of this re-atomizer. The ejector effect on the four tubes which extend into the throat tends to draw into the annulus any liquid gasoline which may be passing up the wall of the carbureter and to eject it from the tubes in an atomized condition so that it floats in the air stream and goes equally to the different cylinders.

It is claimed that this re-atomization of the gasoline makes it possible to adjust the carbureter for a much leaner mixture, thus lowering the fuel consumption and reducing crankcase dilution.

THERE is a grave necessity for adequate records covering inventions, if the inventor is to gain the full fruits of his ideas and labor. "Where litigation cannot be avoided, thousands of dollars are lost annually by the failure of inventors and their associates to keep adequate records of their inventions, their development and reduction to practice, and early commercial history. . . . This expense is unnecessary if adequate records are kept of the essential steps and their dates in connection with inventions."

To point out these essential steps and direct the inventor how to take them is the purpose and scope of the little volume on "How to Keep Invention Records," recently published by D. Appleton & Company.

The first part of this 82-page volume discusses the general nature of industrial property and monopolies granted to protect it. A practical method of insuring this recording of dates is presented in the second part, while a final chapter deals with methods of patent investigation.

Some New Parts Seen at the New York Show

Two new axles, one of which uses two cone clutches in place of differential, are shown. New flexible universal of laminated steel, an automatic advance magneto coupling, and a lubricating system for transmission universals and axle, are among the recent developments.

By P. M. Heldt

A NEW line of axles was exhibited by the U. S. Axle Co. The front axle is designed to permit turning in a small radius and will be made for either right or left hand steering. The axle center and steering knuckle are drop forgings, heat treated. The steering knuckles swing on adjustable tapered roller bearings and the front wheels turn on bearings of the same type. The steering arms, of drop-forged chrome vanadium steel, are designed with a high factor of safety. The tie rod is behind the axle center and thus well protected. It is made of seamless steel tubing tapered toward both ends. This axle has a load capacity up to 1400 lb.

The rear axle is of the semi-floating type with helical bevel gear drive. It has a load capacity up to 1900 lb. and can be made in a larger range of gear ratios. The axle shaft housings are of tapered, seamless steel tubing with spring seat and brake anchor riveted to the outer end. The inner ends are flanged and bolted to malleable iron or aluminum alloy gear housings. The pinion housing can be furnished of aluminum alloy or malleable iron, adjustable or non-adjustable type; it carries two adjustable taper roller bearings which take both thrust and radial loads. The drive and differential gears are of alloy steel and the axle shafts of molybdenum steel. Axle shafts are ground to size and are splined to fit the differential; they can be easily removed without disturbing either the gear housing or the differential assembly. The outer end of the shaft is mounted in a self-aligning, double row ball bearing. A heavy spring is inserted between the wheel hub and the ball bearing to minimize lateral shocks.

Hubs of symmetrical design are furnished, for wood, wire or disk wheels. Both the service and emergency brakes are of the expanding type and are arranged side by side within the same drums. The service brake is 1¾ in. wide and the emergency brake 1 in. The pressed steel brake drum is 14 in. in diameter and the brakes are actuated by means of cams. The reason given for using expanding brakes only is that where contracting brakes are used it often happens when non-skid chains are fitted the cross chains tear, catch the brake rigging and practically rip it off the axle.

A rather radical design of rear axle was exhibited by the Stokes Engineering Co., Inc. No differential gear is used, but instead there are double friction clutches in each wheel, of the conical type. These clutches are operated automatically by means of steep pitch, square thread screws in the hubs of the central driving gear. One of the clutches is used for forward drive and the other for reverse.

A universal joint employing flexible members of laminated steel was exhibited by Chilton Universal Joint, Inc. The laminations are made by punch press operations of

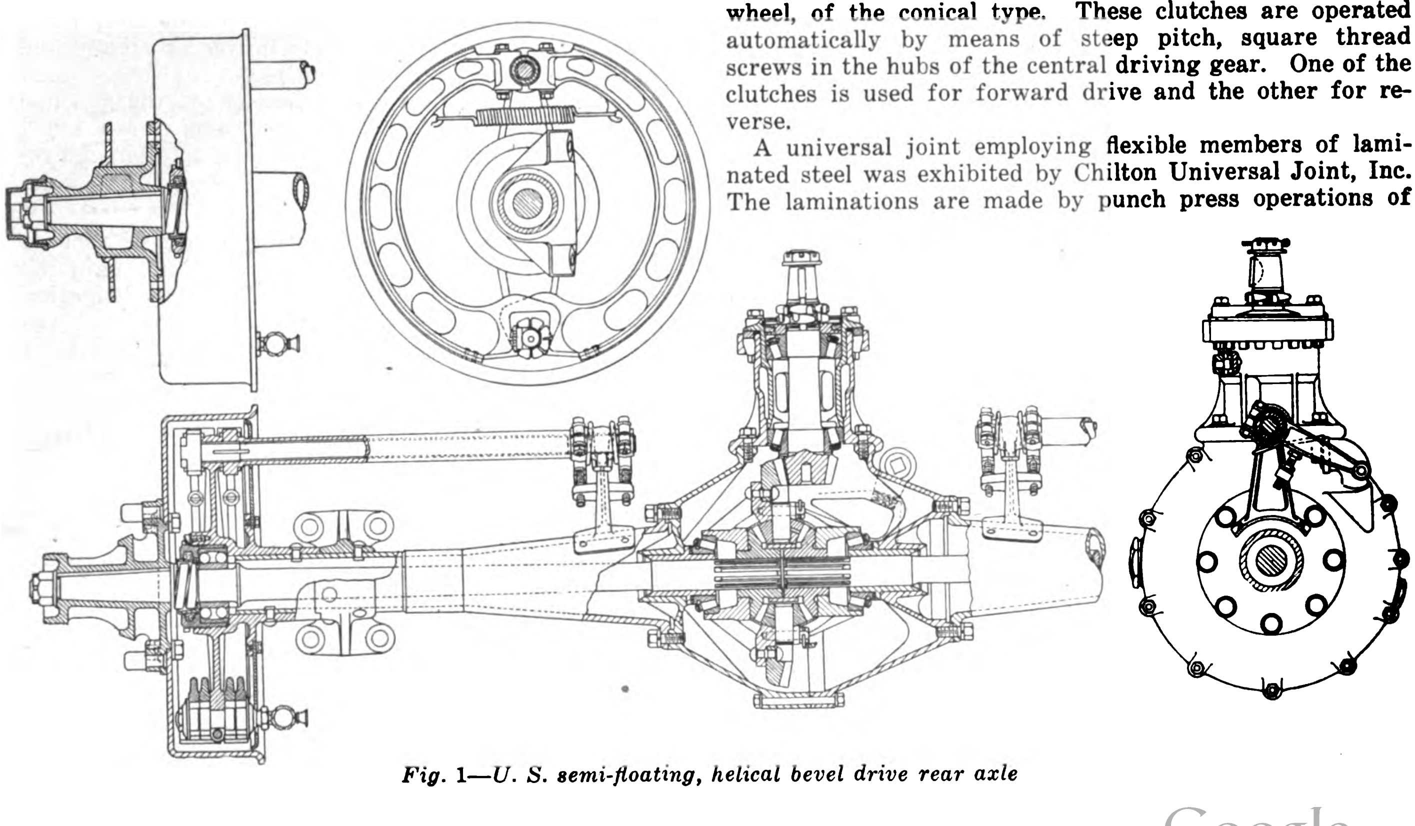


Fig. 1—U. S. semi-floating, helical bevel drive rear axle

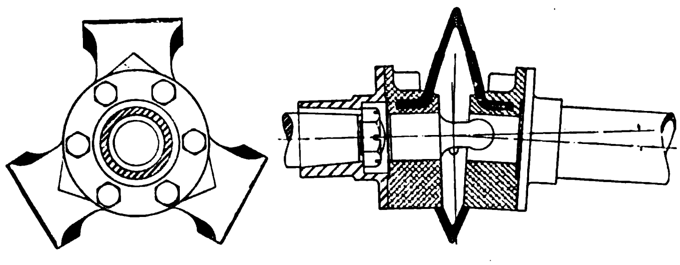

Fig. 2—Chilton flexible universal joint

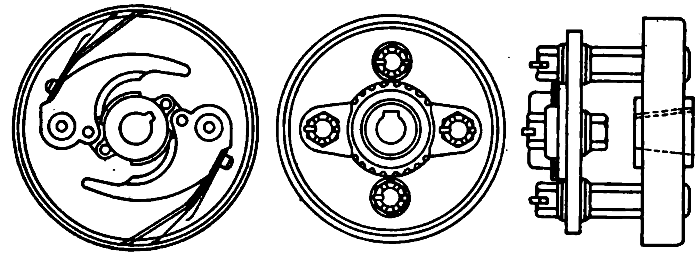

Fig. 3—Splitdorf automatic advance coupling

tempered and polished blue spring steel strips. The hubs are flanged for connection to the usual automobile transmission shaft flanges; they are of a special alloy and are cast around the ends of the driving springs in permanent mold machines. The spring ends extend far into the hubs and are notched to insure a perfect bond. It is stated that on tests to destruction the springs will be broken without loosening in the hubs. Three sets of laminae are used in each joint. As the flexible members are cast in the hubs the whole joint is one piece, and it requires no lubrication or attention by the operator. The illustration shows the construction. When two of these universals are used in an automobile drive no slip joint is required.

The Splitdorf Electrical Co. has brought out an automatic advance coupling for magnetos. It consists of a centrifugal governor of simple and compact design as shown in Fig. 3. The governor weights are pivoted to the housing and connect by links to a spider on the shaft in such a way that as the weights move outward from the axis of rotation under the action of the centrifugal force and against the pressure of laminated springs secured to their outer sides, the shaft is angularly advanced relative to the housing substantially in proportion to the speed. The Model V is made for truck and tractor engines and can be installed on any Splitdorf magneto without change in the magneto. The minimum advance is obtained at 600 r.p.m., the maximum at 1300 r.p.m. The coupling weighs only 1 lb. 3 oz. Model W is designed for use on passenger car engines. It gives a minimum advance at 400 r.p.m. and a maximum advance at 1800 r.p.m., the weight being 1.5 lb.

A transmission and drive lubricating system was exhibited by the Merchant & Evans Co. A gear type pump is located in the rear axle housing, an oil reservoir on the forward side of the dashboard and a sight feed or circulation indicator on the instrument board. The oil from the reservoir passes through the transmission, the hollow propeller shaft and the hollow bevel pinion shaft into the differential housing. While the car is standing there is a tendency for the oil to flow toward the rear by gravity and when it is first started up the oil level in the differential housing is somewhat above normal. As soon as the car is started the pump delivers some of this oil through the circulation indicator to the reservoir, movement of the oil continuing until the level in the differential housing falls below the pump inlet. The indicator therefore will show oil flow only for a short period after starting the car. One of the advantages claimed for the system is that by maintaining a constant oil level in the rear axle housing oil leakage from the axle is prevented. In order to apply it to a car it is necessary that the universal joints as well as other parts lubricated be oil-tight. When first filling the system the oil should preferably be heated, as it will then flow more freely. It is necessary to add about a pint of oil to the supply in the tank every month. A test plug is located in the differential housing at the level at which it is desired to carry the oil, and oil is poured into the tank until it begins to flow from the test hole.

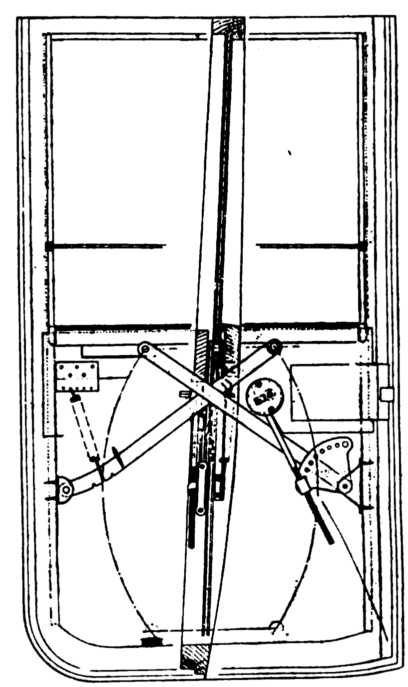

Fig. 5—Crank type of Dura window regulator

Models of the Dura window regulator were shown by the Dura Mechanical Hardware Co. This window regulator for closed cars is made in three types, the lever type, the crank type and the Clement type. The advantage of the lever type is that it permits the window to be raised and lowered very quickly, with less than half a turn of the lever. The weight of the window is counter-balanced by a spring. The full depth of the door pocket space can be utilized. For a certain class of work the crank type of regulator seems to be required. The lever and fulcrum mechanism is retained, but the lever is operated through a crank, a pair of helical gears and a screw and nut.

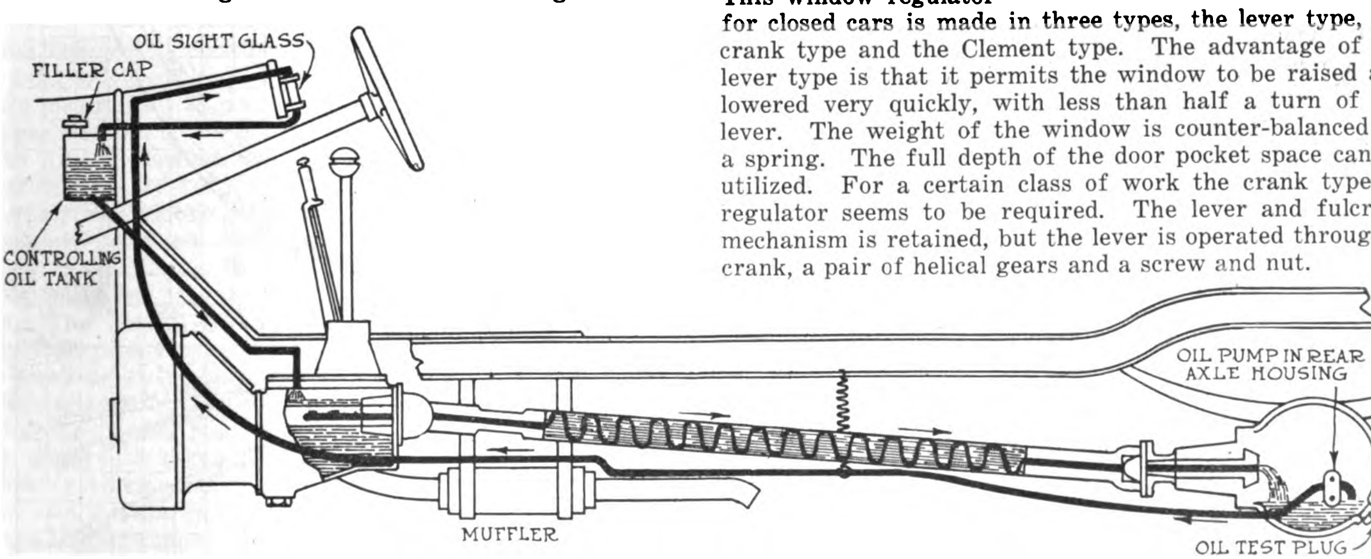

Fig. 4—M. & E. transmission and drive lubricating system

Broader Viewpoint Needed in Effort to Solve Fuel Problem

Author demonstrates the importance of breaking away from outworn notions, and shows how by thorough tests and careful analysis of results it has proved possible to nearly double the mileage of a given car per gallon of fuel, while at the same time power is increased, and general performance bettered. New constant clearance piston also described.

By A. L. Nelson*

THE object of this paper is to appeal for a broader viewpoint and give a few illustrations and tests which show that the solution of a problem may lie in an entirely different method than that which often becomes stereotyped by sheer usage, rather than by its specific merit. We know off-hand the general engine characteristics of our engines at full, three-quarter, one-half, and one-quarter load. We know the power, friction losses, economy and the like. This is all very proper and applies very well to what the engine *can do*, but how about the more important questions of engine characteristics while working at loads that it is *called upon to carry* in the car? How much specific information can we give off-hand on these more important engine characteristics so vital to the solution of the fuel problem?

Power Required to Drive the Car at Constant Speed

Fig. 1 shows the engine brake horsepower required to drive the car tested, the brake horsepower available and the percentage of available power used at each speed.

The method of obtaining these data was to drive the car on a given course at constant speeds corresponding to a fixed carbureter throttle setting, then to remove the engine from the car to the dynamometer stand and determine the power developed at those settings and the engine speed corresponding to the car speeds. It was necessary to duplicate very accurately the fixed throttle settings when the engine was put on the dynamometer; hence, a micrometer adjusting screw was attached to the carbureter throttle-shaft. The speed of the car was obtained by timing with a stop-watch on a ½-mile measured course, driving in both directions for each setting, to eliminate the effect of wind resistance, and taking the average speed. The engine speed was calculated from the number of revolutions per mile made by the rear wheels. Several important details, such as cooling water temperatures, oil temperatures, air pressure under the engine hood, and the like, need not be given here. For accurate work it is suggested that, in addition to the use of fixed throttle settings, manometer readings be taken of the intake-manifold depression together with the air temperature. Referring again to Fig. 1, note that at average driving speed the engine is working at only 16 to 19 per cent of full load. Poor economy is caused by misapplication of the engine rather than poor engine economy. The analysis should give us relative values on which to consider the feasibility of using two-speed rear axles, or more speeds in the transmission. Or

Particulars Concerning Car Tested, Test Conditions, Course, etc.	
Outdoor temperature (average), deg. fahr.	76
Barometer (average) in. of mercury	30.15
Weight of car with fuel and two spare tires, lb.	4,340
Weight of driver, lb.	180
Total weight of car and driver, lb.	4,520
Tires	Firestone Cord
Size of tires, in.	33 x 5
Air pressure, rear tires, lb. per sq. in.	50
Air pressure, front tires, lb. per sq. in.	45
Course	Indianapolis Speedway
Pavement	Brick
Length of course, miles	½
Direction of driving	North and south
Revolutions of rear wheel per mile	600
Exhaust cutout	Open

perhaps an entirely new and better way will be devised eventually to keep the load factor of the engine high to obtain better economy.

The conditions revealed by the correlation of engine and car characteristics are so bad as to make it evident that both the public and engineers need a decided change in viewpoint; the public in what they demand, and the engineer in what to furnish and in what to educate the public to expect.

Higher Compression Ratios

As an illustration of the need for change in viewpoint, let us consider the effect of using higher compression ratios. We all know that the compression ratios used in aviation engines give us much higher fuel economy than those used ordinarily in automobile engines. Then why not use high compression ratios for automobile engines? We are told that higher compressions make the engine knock badly. The simplest and generally accepted way of getting rid of knocking is to lower the compression ratio. Shall we accept this way as final? Why not try to accomplish the same result some other way and at the same time maintain the higher economy?

An engine at full load may knock badly at 500 r.p.m. and perhaps will not knock at all at 1200 r.p.m. If we study the curve of brake mean effective pressure, we will find that, at 500 r.p.m., the brake mean effective pressure is greater than at 1200 r.p.m Curve *B*, Fig. 2, illustrates this. By lowering the compression to eliminate the knock, we obtain curve *A*. Suppose we go back to the higher piston compression ratio and at the same time we delay the inlet-valve closing. Experiments show that we get a brake mean effective pressure in accordance with curve *C*, the peak of the curve coming at a higher speed than that given by the conventional timing. The pressures at the lower speeds are reduced, which is the desired result to overcome the knocking, while the pressures at the higher speeds are materially increased.

The exact timing to use depends on the valve sizes, intake passages, carbureter characteristics and similar factors. The results obtained are more far-reaching than merely keeping the pressures within a range to eliminate the knocking at the lower speeds, and increasing the power at higher speeds. The most desirable results are obtained under car-driving conditions. The small charge of mixture required is taken into the cylinder and compressed to a smaller volume than in the case of the lower compression; also the charge is purer, due to the better scavenging of the higher compression pistons. Tests for 5 to 1 and 4.25 to 1 compression ratios at full load show increases of 13 and 24 per cent in the brake thermal efficiencies at 700 and 2100 r.p.m. respectively; while at these same speeds and at loads required by the car the increases are 22 and 41 per cent respectively. (See Figs. 23 and 24, at 20 and 60 m.p.h.. respectively.) These results are representative of only the first attempt, yet they are quite appreciable gains in economy, due solely to the change in compression ratio.

Consider next the aluminum piston, which is almost universally used in aviation engines. The high thermal conductivity of aluminum allows the heat to flow from the pistons more freely than from any other metal commonly used, contributing highly to the best known results obtained from high-speed internal-combustion engines. Why are the aluminum pistons for automobiles, though largely used, condemned by some of our leading designers of national reputation? They know the sterling qualities of the aluminum aviation pistons that make the high power and economy of aviation engines possible, yet for their automobile engines they use cast iron which perhaps could not possibly be used in the aviation engines with the high compression ratios. They tell us the trouble is that the aluminum pistons expand so much when heated that they require excessive cylinder clearance and that this allows them to slap at the lower speeds, or, if fitted closer, to stick at the higher speeds. As an alternative they select cast-iron pistons, use lower compression and get lower economy and greater torsional vibration of the crankshaft due to the heavier reciprocating parts and occasionally scoring the cylinder blocks. Some engineers say, in addition, that the hotter cast-iron piston helps to vaporize the liquid fuel that comes in contact with the head of the piston.

Constant-Clearance Aluminum Piston

The specific heat of aluminum is greater than that of iron, but the density of iron compared with that of aluminum gives us a heat capacity per unit volume of aluminum only 68 per cent that of iron. However, the conductivity of aluminum is 2.85 times that of iron. From these figures it will be seen that even if the iron piston was 1½ times as hot as the aluminum piston, the heat flow to the liquid fuel in contact with the aluminum piston-head would be about 30 per cent greater, and that, for same temperatures, the heat flow would be about 94 per cent in favor of the aluminum.. Since the aluminum piston-head is usually made thicker than that of cast iron, the amount of heat available would be approximately the same in both cases. It appears that the two pistons are on a par, except that heat flow is greatly in favor of the aluminum piston. It has become a habit to think that aluminum pistons must expand. Why not design an aluminum piston that cannot

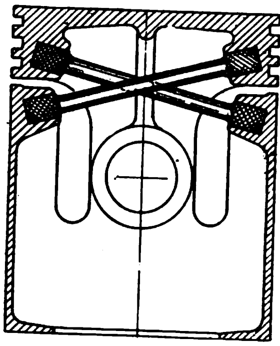

Fig. 5—Type of aluminum piston in which clearance increases as the piston is heated

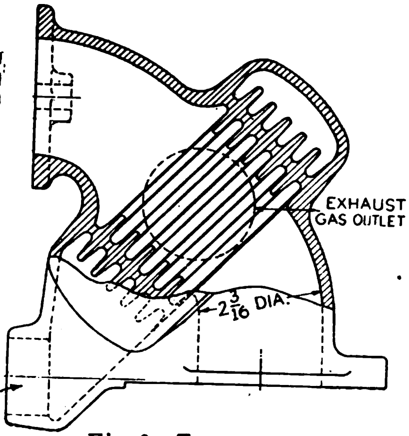

Fig. 6—Transverse section of intake pipe, showing exhaust heated ribs for vaporizing fuel

expand as far as cylinder clearance is concerned? This viewpoint changed the complexion of the whole problem and led to the development of an aluminum automobile piston design that gives results believed to be in advance of the combined merits of the aviation piston and the cast-iron piston.

This piston is illustrated in Fig. 3. In this design the adjustable *steel* strut controls the cylinder clearance in the direction which prevents piston slap. It will be noted that the *aluminum* has nothing to do with the cylinder clearance. The strut is subject to almost the same temperature range as the cylinder; hence, the clearance remains constant through the range from a stone-cold to a steaming-hot engine. This type of piston proved very successful from the outset. It is the only type of piston, regardless of material or design, that we have not been able to make stick under abnormal conditions. It has absolutely no slapping tendencies even in a stone-cold engine. Maximum car speed can be maintained indefinitely without causing the pistons to stick. For a more severe test the pistons were run at full load for 30 min. at 3000 r.p.m., with the radiator cooling water shut off so that the engine steamed continuously during the run. This run was made at the end of a full day of high-speed testing with no provision for cooling the oil.. The cylinder clearances of the pistons were less than those of any cast-iron pistons that are so far as we know used in quantity production. Two of the pistons had cylinder clearances of 0.0015 in., based on the diameter. The other four pistons had clearances from 0.0020 to 0.0025 in.

In spite of all the abuse we have been able to impose on this type of piston, the pistons have always come out of the tests entirely free from any scoring marks and show a decided general tendency to polish-up smoother than the conventional aluminum piston. This undoubtedly follows from the maintenance of the proper clearance at all times, thus avoiding excessive bearing loading. Another striking characteristic of the pistons is their smoothness of operation, indicating that even when the slap in the conventional piston is not audible there is a rumbling sound which becomes noticeable when compared with the operation of the constant-clearance piston. This difference is very marked at both high and low speeds. When the pistons are used with the conventional timing, the knock at full load and low speeds is very materially subdued compared to the conventional type of piston. This clearly shows that cylinder piston clearance has much to do with the degree of audibility of the knock.

Fig. 4 illustrates a design which has the strut cast integrally with the "slipper" portion of the piston, the latter being well insulated from the heat of the piston-head by being separated from it. An alternative of this design is a steel strut cast in place or fastened in some suitable manner.

Fig. 5 illustrates an aluminum piston that *contracts* when heated, so far as cylinder clearance is concerned. The steel struts in this case are shown cast in place. The reason the cylinder clearance increases with the heat on the piston is that the ends of the steel struts attached to the piston-ring-groove portion of the piston-head are carried outward, drawing the "slipper" portion inward since they are attached to the opposite ends of the struts. A large variety of designs can be made embodying the strut idea to accomplish variations of cylinder clearance adjustment and the like, as may be desired for particular cases. It is hoped that these piston illustrations will fix the idea firmly that, so far as cylinder clearance is concerned, we have nothing to fear from the highly expansive aluminum as a piston material.. As for the practical merits of the constant-clearance type of piston, they must be tried to be appreciated, because the results they give are so far in advance of one's highest expectations. The results are indeed a striking illustration of what can be accomplished by a mere change in viewpoint.

Fuel Vaporizer

Consider now the general experience with exhaust-heated intake-manifolds. It is generally agreed that the results are fairly good, at the expense of a loss of maximum power due to heating the air. On heating the fuel by "hot-spots," the air is also heated. The experience has been so general that it has practically fixed in many minds as an irrevocable fact that using exhaust heat must necessarily and unduly heat the air. To show that this is not the fact, first let some suppositions be given which can be agreed to readily.

Suppose we run all the hot exhaust gases through a jacketed intake pipe, say some 10 in. long, to get ample surface for the "hot-spot"; that is, ample surface to transmit the exhaust heat required to vaporize the fuel, which, it has been observed, goes to the walls of the intake pipe or points of lowest air velocity. Such an intake pipe works well but it also heats the air, coming into contact with the large highly heated surface with the result that the maximum power cannot be obtained. Suppose we now corrugate the intake-pipe so that the air passage is say 2½ in. long, without reducing the area of the inner or outer surface. Fig. 6 shows a cross-section of such an intake pipe designed for the 295.2-cu. in. six-cylinder engine used in the tests. Note the relatively small amount of exterior exposed surface of the heating chamber, an important item for starting out with a cold engine, and the efficient heating of the pipe at low car speeds. The heated portion of the pipe is set at an angle above the carbureter so that the inertia of the fuel globules will throw them directly into the large highly heated surface. The flow of liquid following the wall is toward the inner or smaller radius of the bend. Gravity helps to make the liquid flow over the heated surface. It cannot get out again into the air-stream before being highly vaporized. The highly heated corrugated surface effectively traps the fuel and quickly vaporizes and super-heats the vapor. Tests indicate that the air is very slightly heated while the fuel is highly vaporized. Kerosene is vaporized as readily as gasoline, even at speeds as low as 200 r.p.m. with wide-open throttle. The air is slightly heated because only a very small portion of the air comes in contact with the edges of the ribs at the inner diameter. Tests in which the intake-pipe was *abnormally* heated, have been run with a loss of only 1.2 per cent of power at 1200 r.p.m. and 2 per cent loss of power at 2400 r.p.m., compared with the best results that could be obtained from the most favorable degree of heat or from unheated plain manifolds. The design as shown

does not strictly confine the heat to the ribbed portion for practical reasons.

The effect of the intake pipe construction upon the remainder of the intake passages to the cylinders is very important. Off-hand it would appear as though the deep ribbing would offer a severe obstruction to the fuel passing to the cylinders. Let us compare what happens with that of the ordinary manifold where the fuel as a rule travels very much slower than the air-stream flowing along the manifold walls. A considerable time interval occurs between the time the fuel leaves the carbureter nozzle and the time it reaches the cylinder. In the case of the intake pipe, Fig. 6, and the remaining passages to the cylinder, the heavier parts of the fuel are momentarily arrested, but they are highly vaporized quickly and pass to the cylinder at the same speed as the air-stream. Since a highly heated surface can be used without heating the air, the vapor becomes so highly heated that it does not condense while in the air-stream. Of course, the vapor going into the air-stream receives a high velocity on the outset, and the time interval for it to condense is small.

Most convincing observations are made when applying 2-in. carbureters to the engine, both on the dynamometer and on the road. For speeds below 800 r.p.m. with open throttle, the plain unheated intake-pipe could not be used at all. Even at higher speeds the economy was poor although the power was good, indicating poor distribution. With the new design intake-pipe the engine could be run as low as 200 r.p.m. with wide-open throttle. However, this was not true with 2-in. plain-tube carbureters which we have tried without making structural modifications in the design.

Application of the exhaust-heated intake manifold made

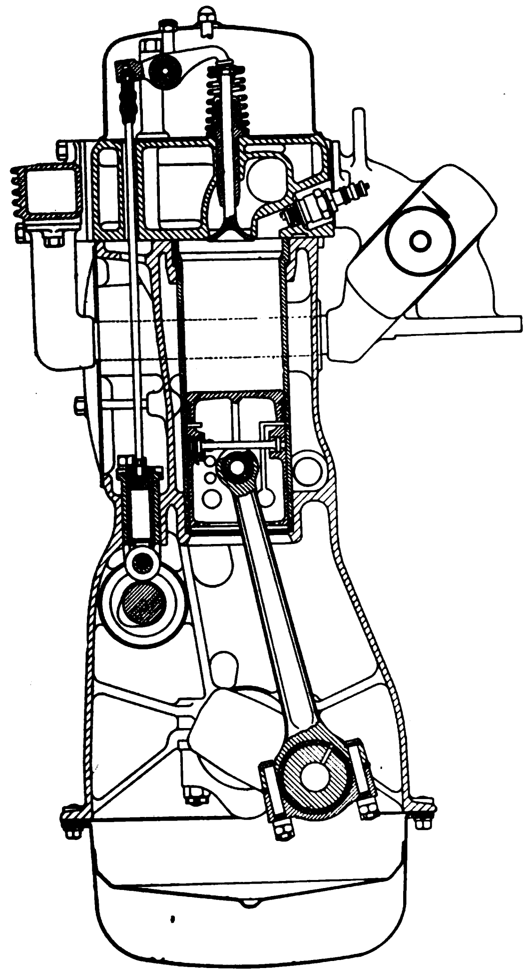

Fig. 7—*Transverse section of engine used in the test*

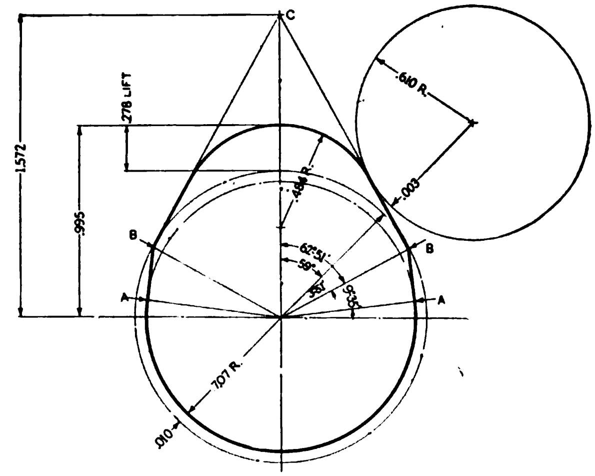

Fig. 8—Inlet and exhaust cam layout. AB and BC are straight lines intersecting at sharp angle at B

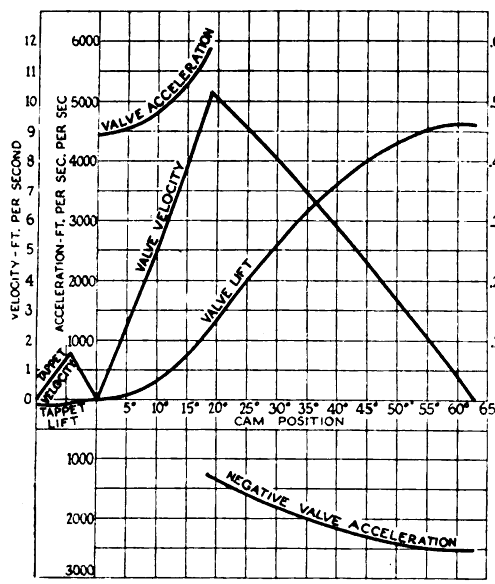
it possible to equip the engine with a 2-in. carbureter. The car accelerates well in cold weather, without using a choker, by the time it can be driven out of a cold garage onto the street. A manually operated valve is provided to force all the exhaust heat through the intake. This is used until the engine heats to the normal operating temperature, or it can be left on continuously without causing any harm except a slight restricted exhaust passage for high speed in this particular experimental design. The good acceleration while cold indicates super-heating of the fuel; in other words, it does not condense materially before reaching the cylinders, even when the engine is cold. When using the larger carbureter and developing correspondingly higher power at both low and high speeds, there is a smoothness in operation that never was obtained with smaller carbureters. The degree of flexibility, smoothness, economy and power are far in advance of the best previous results. The engine shows good torque, right down to the point of stalling. It is believed that even these preliminary investigations show that the conventional hot-spot method can be far surpassed and that the fuel can be heated without unduly heating the air. Here again the results obtained are a direct result of the change in viewpoint.

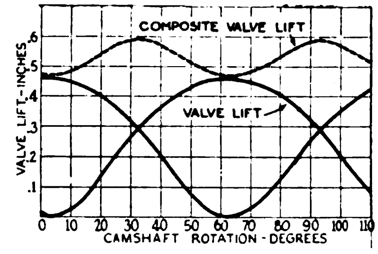
We will next consider tests showing the effect of a proper correlation of car and engine characteristics using 4.25 to 1 and 5 to 1 compression pistons in the same engine. First a brief description of the engine and testing apparatus will be given.

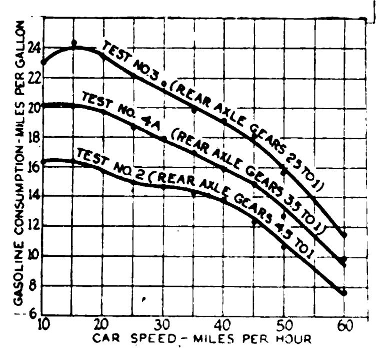
The Engine Used in the Test

The engine used in the test is a valve-in-head type with six-cylinders, 3⅜ x 5½-in. (295.2-cu. in. displacement). The cylinder block and upper crankcase is a one-piece casting of aluminum alloy, with inserted cylinder sleeves of cast iron machined all over. The cylinder-head is of cast iron and detachable. Fig. 7 shows a cross-section of the engine and gives a fairly good idea of the detailed construction. The crankshaft is of the three-bearing type and of liberal dimensions. The hollow crankpins are 2¼ in. in diameter and 1¾ in. long. The shaft is drilled for oil passage at 25-lb. per sq. in. pressure to all the main and connecting-rod bearings.

Attention is called to the unique cylinder-sleeve construction with particular reference to the application of the packing at the bottom of the sleeve. The sleeve at the bottom diameter has a snug slip fit in the aluminum case. The sleeve, however, has been shown to have a very slight axial movement here. This follows from the fact that the aluminum case is not subject to as great a temperature range as the cast-iron sleeve, the higher







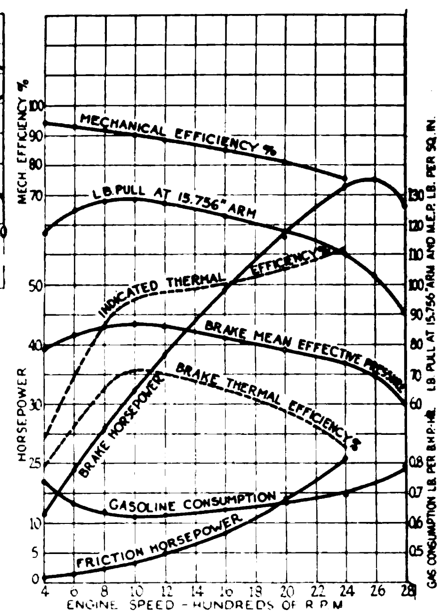


Fig. 9 (at left)—Characteristic curves of mechanism at engine speed of 3000 r.p.m. Fig. 10 (center, above)—Curves showing how inlet valves overlap in the six-cylinder engine used. Fig. 15 (at right)—Characteristic engine performance curves at full load. Compression ratio 4.25 to 1. Fig. 16 (center, below)—Curves showing relation between car speed and fuel consumption, with compression ratio of 4.25 to 1

coefficient of expansion of the aluminum being offset by the greater temperature range of the sleeve. The pressure on the combination cork and hydroil packing is in an axial direction only; that is, there are no radial components of pressure from the reactions of the packing to throw the sleeve out of round. This is the characteristic difference from other types of sleeve constructions and is necessary to make sleeve construction successful.

Fig. 8 gives the details of the inlet and exhaust cams, both cams being identical. This is a special type of cam* having a zero opening and closing valve velocity regardless of engine speed.

Fig. 9 gives the valve-mechanism characteristic curves for an engine speed of 3000 r.p.m. Attention is called to the design to obtain a high acceleration away from the cam and a low acceleration toward the cam; that is, the acceleration that must be produced by the valve spring to keep the roller following the round peak of the cam, the 0.484 in. radius shown in Fig. 8. The equivalent weight of all the accelerated parts considered placed at the valve is 0.7635 lb. The valve-spring pressure required at 3000 r.p.m. is 59.8 lb. per sq. in.; at 3200 r.pm. it is 68 lb. per sq. in.; at 3400 r.p.m. it is 76.8 lb. per sq. in. Great care is taken to have the master cam ground to a true radius at the peak of the cam. If the cam generated has any bumps on the peak radius, it is impossible to obtain high-speed operation for two reasons. The irregularities set up synchronous vibrations in the valve springs and the accelerations are immensely increased, making the springs too weak. For instance, if the 0.484 in. peak-radius has waves on it of 3/16-in. radius, the acceleration is increased 116 per cent. These points are mentioned because they are absolutely vital to the successful application of the valve mechanism of the roller type to a valve-in-head engine operated at high speeds.

Fig. 9 gives the inlet-valve timing overlap. This diagram shows that although the inlet-valve is held open fairly late, the valve of another cylinder is close to its maximum lift, preventing a blow-back into the carbureter. The valve timing is as follows: Inlet opens 4 deg. past top center and closes 60 deg. past lower center. Exhaust opens 52 deg. before lower center and closes 4 deg. past top center.

Fig. 11 shows a diagram of the intake-manifold passages. These are cast within the cylinder-head, making them of the shortest possible length. The firing order is 1, 5, 3, 6, 2, 4; therefore, the flow of gas is continuous in both directions from the center. The average gas velocity at 3000 r.p.m. at manifold inlet is 181 ft. per sec.; just above the valve it is 192 ft. per sec. and at full lift of the valve it is 247 ft. per sec. The throat diameter of the valve is $1\frac{1}{2}$ in.; the outside diameter is $1\frac{5}{8}$ in.; the valve lift is 0.445 in. The area at manifold inlet is 3.39 sq. in. The tulip-shaped inlet-valve is used to lessen the resistance and keep the velocity of the gas as high as possible on entering the cylinder as an aid to turbulence.

Fig. 7 shows the exhaust-gas pipe between the two center cylinders. The engine is equipped with a Delco generator and single breaker-point type of ignition, with automatic and manual spark advance. A Willard battery was charged during the tests and also was used for starting. Champion —Toledo No. A-63 metric two-piece plugs were used for all the runs. These plugs had much to do with the ease with which the tests were run. Only six plugs were used and at the end of the runs they were in perfect condition. This is saying a great deal for the spark-plugs, considering the high-compression pistons, power output and speed of this engine.

Fig. 12 shows the 2-in. Johnson Model B carbureter used. The air-valve spring and strangle tube were first worked out for the low-compression piston tests. The same parts worked out nicely in connection with the 5 to 1 compression pistons, with only a slight change of adjustment on the air-valve spring. Otherwise, in each set of tests, all adjustments were kept constant for both partial and full-throttle loads.

With the Sprague electrical dynamometer and the fine throttle adjustment, the proper load and speed were obtained readily.

The section at *AA* in Fig. 13 shows the equal distribution of the cooling water to the cylinder sleeves. The water goes from the pump to the tube inside the cylinder block. Two holes for each sleeve give a uniform distribution of the water. This keeps all the sleeves at the same temperature, an important feature for equal gas distribution and smooth running. The engine cooling

*A detailed description and mathematical analysis of this type of cam will be found in the 1917 S. A. E. *Transactions*, Part 1, pages 328 to 337.

water circulates through a standard radiator such as is used on the car. The radiator is cooled by circulating water from an outside source around the outside of the radiator; that is, the cooling medium is water instead of air as used in the car. However, since the water passing through the engine has the same resistance as in the car, it has the same temperature drop, for the quantity circulated is the same in each case. The temperature of the engine water is controlled very easily by this apparatus, and car conditions are duplicated. The temperature of the engine water outlet was kept at 150 deg. fahr. for all the tests.

Fig. 14 is a photograph of the connecting-rod, inlet-valve, exhaust-valve, piston-pin and the pistons. The connecting-rod length is 11 in., the weight complete with bearings is 46.35 oz. and the center of gravity is 2.60 in. from the center of the crankpin end.. Two pistons are shown at the upper part of the photograph. The one to the left gives the 4.25 to 1 compression ratio; the one to the right gives the 5 to 1 compression ratio and is of the constant-clearance type. At the bottom the latter piston is shown from a different angle. A set of 4.25 to 1 compression pistons of the constant-clearance type was not available for the comparative tests; however, 1/8-in. wide piston-rings were used in each case and the 4.25 to 1 compression pistons were relieved at the side in an endeavor to give the pistons approximately the same bearing area as the other pistons. The cylinder clearance given the low-compression pistons was 0.005 to 0.006 in. and that of the high-compression pistons 0.0015 to 0.0025 in. The weight of three 1/8-in. wide piston-rings is 1.82 oz.; that of the 4.25 to 1 piston, 13.52 oz.; that of the 5 to 1 piston, 18.65 oz.; and that of the piston-pin, 5.60 oz. The weight of the complete engine without the clutch is 660 lb. The weight of the complete powerplant, engine, clutch and transmission is 780 lb.

Testing Apparatus

A Weston tachometer was used to indicate the speed. This was checked repeatedly by a revolution counter throughout the entire range of speeds used. The engine cooling-water temperature was obtained by a radiometer calibrated for the range used.

Particular care was used in weighing the fuel for each run. Two fuel tanks were used, one for a general supply and the other for weighing the fuel consumed in 120 sec. The time interval was obtained from the second hand of a watch and the use of a three-way valve connecting the two tanks to the carbureter. Both tanks were equipped with gage glasses so that the level of gasoline could be kept almost the same. This scale balances readily within 1/100 oz., even when the rubber tubing connected with the fuel line is in place.

During the tests the windows of the laboratory were opened and the room temperature kept close to 65 deg. fahr. on all the runs. The average barometer readings for comparative tests Nos. 1 and 5 were 30.23 and 30.22 in. of mercury respectively. The gasoline used was Target brand, made by the Western Oil Refining Co. The weight of a sample gallon was 96.80 oz. and the heat value per pound was taken as 19,500 B.t.u. in the calculation of the thermal efficiencies.

Comparative Tests

Fig. 15 shows the engine characteristics at full load with the 4.25 to 1 compression ratio. The maximum brake mean effective pressure comes at 1000 r.p.m., with a considerable reduction at 400 r.p.m. due to the delayed inlet-valve timing. The maximum fuel economy is 0.613 lb. per b.hp. per hr. The mechanical efficiency is very good at low speed but drops off rather fast as the speed increases. The peak of the power curve is at 2600 r.p.m.

Fig. 16 shows the results of tests Nos. 2, 4A and 3, in terms of miles per gallon for 4.5, 3.5 and 2.5 rear axle gear ratios and 4.25 to 1 compression ratio. It will be noticed that a material increase in mileage is obtained as the engine load factor is increased by changing the rear-axle gear-ratio.

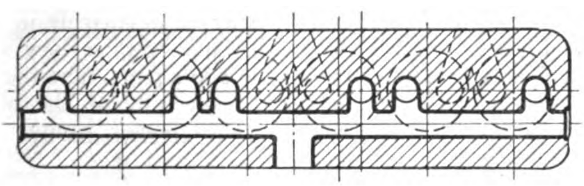

Fig. 11 (above)—Section of cylinder head showing short cast-in intake manifold

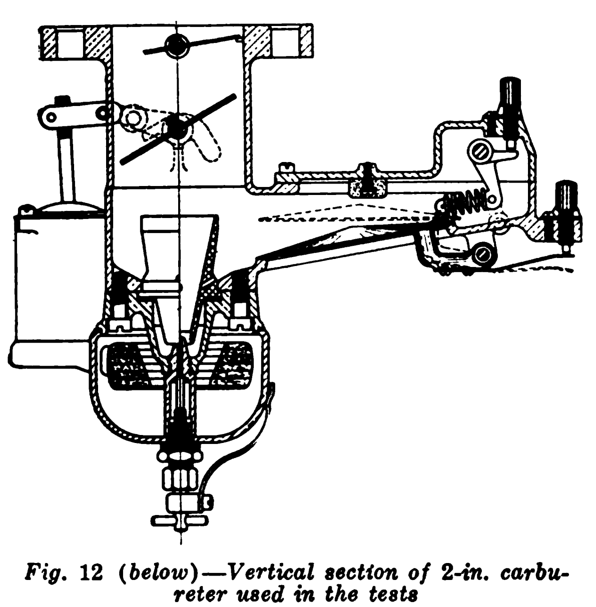

Fig. 12 (below)—Vertical section of 2-in. carbureter used in the tests

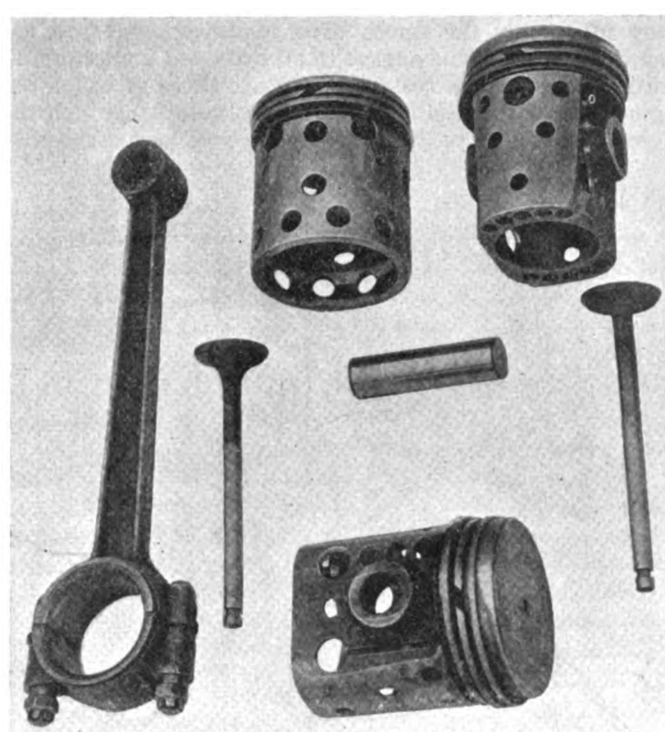

Fig. 14—Parts of engine used in test. Of the two pistons at top, the one nearer the center gives the 4.25 to 1 compression ratio, while that at the right gives a 5 to 1 ratio and is of the constant clearance type. Another view of the latter is seen at the bottom

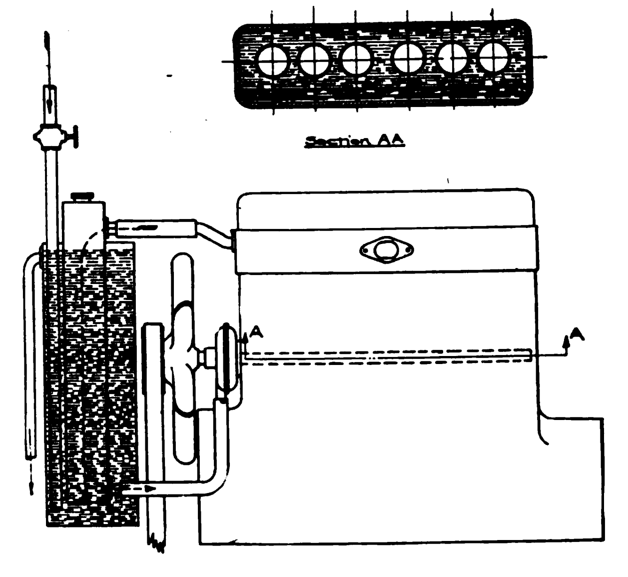

Fig. 13—Diagram of cooling water circulating system, showing method of cooling radiator used during block tests

Fig. 17 gives the engine characteristic under constant-speed driving conditions with 4.25 to 1 compression ratio and 3.5 to 1 axle gears. It will be seen that the full-load brake characteristics have been changed greatly, while the indicated characteristics have changed but little. The friction losses, which include the pumping losses, very materially lower the mechanical efficiency. Note that the engine is pumping against an intake-manifold depression of 15 in. of mercury at the lower speeds and the mechanical efficiency at 800 r.p.m. is only 58 per cent, compared with 91.7 per cent at full load.

Fig. 18 gives the engine characteristic when using the 5 to 1 compression pistons, everything else on the engine being identically the same. The readings given are not "snap" readings. The engine in all tests was kept running continuously and the results shown are those at which the engine runs with stability; that is, the result to which the engine settles at any given speed. It will be noticed that the maximum brake mean effective pressure is still at 1000 r.p.m., but it has increased from 86.2 (see Fig. 15) to 96.9 lb. per sq. in. It will also be noticed that the increase is greater as the speed increases. The peak of the power greatly increased, being 0.527 lb. per b.hp. per hr. at 1000 r.p.m. as compared to 0.613 lb. per b.hp. per hr. in the case of 4.25 to 1 compression. The mechanical efficiency is not as good below 800 r.p.m., but it is much better at the high speeds, being 81.4 per cent as compared with 76.1 per cent at 2400 r.p.m. The maximum brake thermal efficiency is increased from 21.1 to 24.8 per cent.

Fig. 19 gives the engine characteristics at constant car speed, with 5 to 1 compression ratio and 4.5 to 1 axle gears. Fig. 20 is for 2.5 to 1 and Fig. 21 is for 3.5 to 1 axle gears. Fig. 21 can be compared directly to Fig. 17, the only difference being the compression ratios. It will be noticed that the mechanical efficiency has not been materially changed; however, the fuel economy has been very materially increased. It is very gratifying to note that the relative increases are even greater than those at full-load. At 1000 r.p.m., the brake thermal efficiency has been increased from 11.5 to 14.1 per cent, and at 2100 r.p.m. it has been increased from 16.4 to 23.2 per cent.

Fig. 22 shows the miles per gallon at various car speeds for 5 to 1 compression ratio. This can be directly compared to Fig. 16. The results are materially higher all along the line. The overall increase at 15 m.p.h. is from 16.4 to 31 miles per gal., when changing both the compression and the axle gears.

On long road tests the results agree very closely with the curves considering the amount of time the engine is idled and the nature of the driving. On the speedway the results can be duplicated at constant driving speeds. They can be further increased by using light engine oil and higher tire pressure than those used in the tests to set the standard of brake horsepower required.

Comparison of Results

Fig. 23 gives a comparison of the engine full-load characteristics. The comparison as a whole is entirely in favor of the higher compression ratio, but shows a very slight loss in mechanical efficiency below 800 r.p.m. The increase in brake horsepower is marked, especially at the higher speeds. The percentage increase in power ranges from

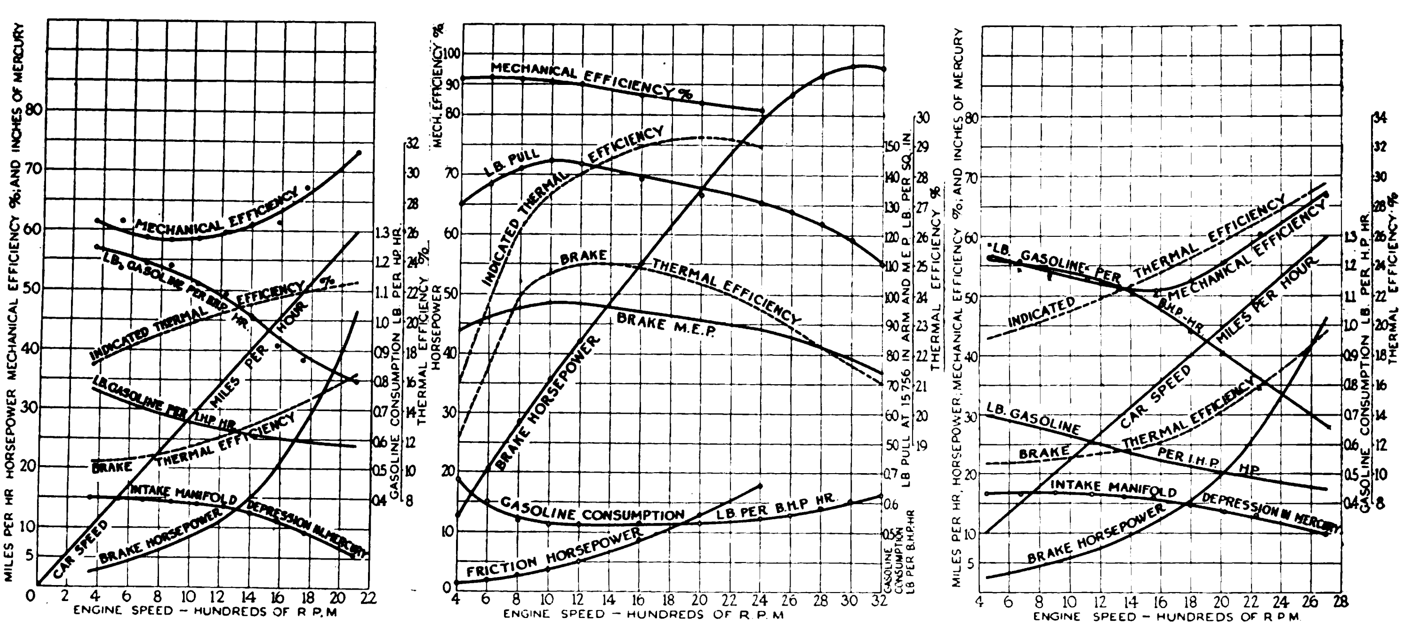

Fig. 17 (at left)—Characteristic curves of engine performance with 4.25 to 1 compression ratio when throttled to give power output sufficient to propel car on level road when using 3.5 to 1 rear axle gear ratio. Fig. 18 (center)—Characteristic engine performance curves at full load. Compression ratio 5 to 1. Fig. 19 (at right)—Same as Fig. 17 but using 4.5 to 1 axle gears and 5 to 1 compression ratio

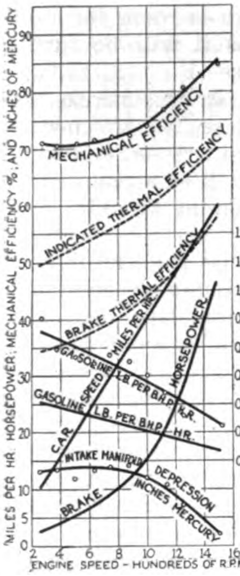

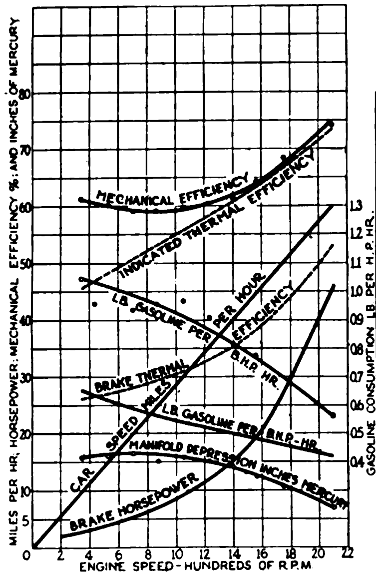

Fig. 20 (*at left*)—*Characteristic curves of engine performance with* 5 *to* 1 *compression ratio when throttled to give power output sufficient to propel car when using* 2.5 *to* 1 *axle gear*

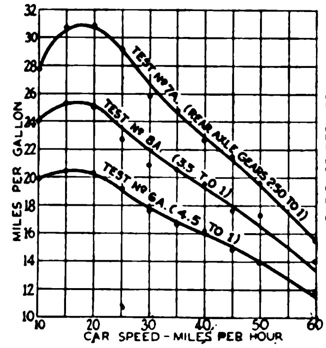
Fig. 21 (*at right*)—*Same as Fig.* 20 *but using* 3.5 *to* 1 *axle gears*

10.5 at 400 r.p.m. to 37 per cent at 2800 r.p.m. The most important increase is that of the brake thermal efficiency. This ranges from 8 to 26 per cent.

Fig. 24 shows the result of increased compression ratio when keeping the rear-axle gears the same; namely, 3.5 to 1. The mechanical efficiency remains practically the same, due to identical engine speeds in each case. The increase in brake thermal efficiency ranges from 19 per cent at 10 m.p.h. to 41 per cent at 60 m.p.h. The saving in gasoline is from 16 to 28 per cent, and, at average driving speed, about 18 per cent.

Fig. 25 gives the comparative results of using the rear-axle gear ratios of 2.5 to 1, and 4.5 to 1, respectively with



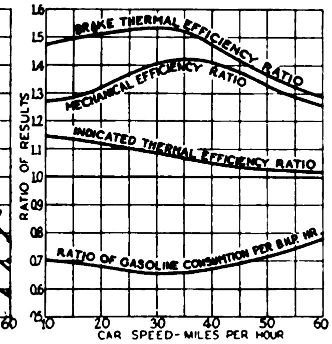


Fig. 22 (*at left*)—*Curves showing relation between car speed and fuel consumption when using* 5 *to* 1 *compression ratio*

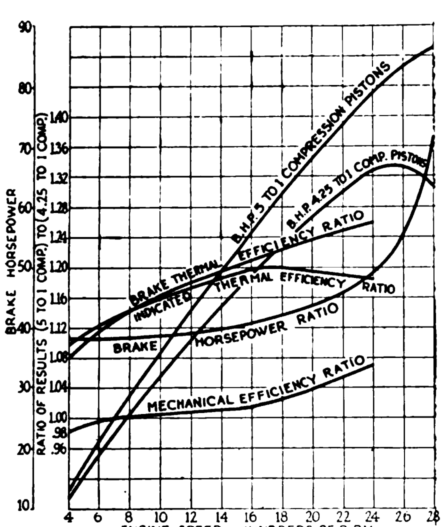
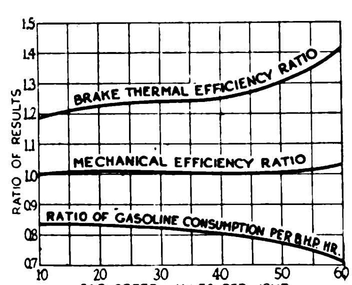
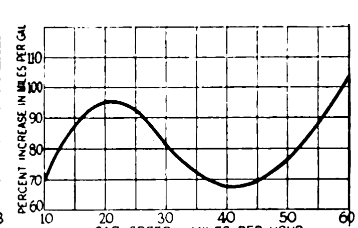
Fig. 25 (*at right*)—*Curves showing the effect of change in axle gear ratio from* 2.5 *to* 1 *to* 4.5 *to* 1 *upon fuel consumption, thermal and mechanical efficiency at various car speeds. Compression ratio* 5 *to* 1

5 to 1 compression ratio. The percentage increase in mechanical efficiency is very marked; the maximum gain is 42 per cent at 36 m.p.h. At 10 m.p.h. it is 27 per cent and at 60 m.p.h. it is 26 per cent. The maximum increase in the brake thermal efficiency is 53 per cent, at 29 m.p.h. It is 48 per cent at 10 m.p.h. and 29 per cent at 60 m.p.h. The gasoline saved is 30 per cent at 10 m.p.h.; 34 per cent at 29 m.p.h.; and 23 per cent at 60 m.p.h.

Fig. 26 gives the percentage increase in miles per gallon in the case of using 2.5 to 1 axle gears with 5 to 1 compression pistons, as against the use of 4.5 to 1 axle gears and 4.25 to 1 compression pistons. The increase in miles per gallon is 70 per cent at 10 m.p.h.; 95 per cent at 20 m.p.h.; 81 per cent at 30 m.p.h.; 68 per cent at 40 m.p.h.; 76 per cent at 50 m.p.h.; and 104 per cent at 60 m.p.h. **These are worth while increases in economy that cannot be passed by lightly, yet they are by no means as great as the economy that is possible.** Let us next consider the economy that is possible even with our present engines. For the sake of a name let us call it the "ideal" economy.







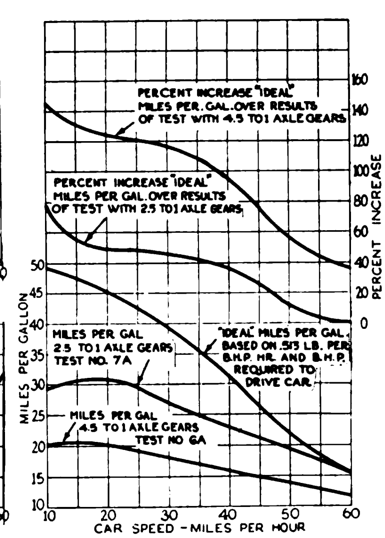


Fig. 23 (*at left*)—*Curves showing comparative effect on engine characteristics at full load of change of compression ratio from* 4.25 *to* 1 *to* 5 *to* 1

Fig. 24 (*center, above*)—*Curves showing effect of change in compression ratio* (4.25 *to* 1 *to* 5 *to* 1) *on fuel consumption, thermal and mechanical efficiency at various car speeds, with* 3.5 *to* 1 *axle ratio*

Fig. 26 (*center, below*)—*Per cent increase in miles per gallon of fuel when using an axle gear ratio of* 2.5 *to* 1 *and compression ratio of* 5 *to* 1, *as compared to using an axle gear ratio of* 4.5 *to* 1 *and compression ratio of* 4.25 *to* 1

Fig. 27 (*at right*)—*Curves comparing economy possible under "ideal" conditions of gear ratio, engine size and load, with economy determined in test when using* 5 *to* 1 *compression ratio and two different axle gear ratios*

We are a long way from the point where we utilize even the economy that is possible with our present engines. Fig. 27 gives a comparison which throws some light on what is meant. This chart is based on the actual engine economy existing at 60 m.p.h. when using 2.5 to 1 axle gears and 5 to 1 compression pistons. The economy is 0.513 lb. per b.hp. hr. Using this economy and the brake horsepower required to drive the car at each speed, we derive a curve that we have termed the "ideal" economy in terms of miles per gallon. It is not meant that this curve is practical with our present system of transmission of the power, but, if the proper gear ratio and engine size are used for any given speed, this economy can be obtained for the size of car used in these tests. From the ideal curve it will be seen that it is possible to get 49 miles per gal. at 10 m.p.h.; 45 at 20 m.p.h., 39 at 30 m. p. h., and 31 at 40 m.p.h. The comparison is made with the results of 2.5 to 1 and 4.5 to 1 axle gears, in connection with the 5 to 1 compression pistons.

The increase in the miles per gallon over that of the results with 2.5 to 1 axle gears is 76 per cent at 10 m.p.h. and 45 at 30 m.p.h. The increase over that of the results of 4.5 to 1 axle gears is 146 per cent at 10 m.p.h., 115 per cent at 30 m.p.h. and 36 at 60 m.p.h. Further, the ideal economy comparison with the results obtained from 4.5 to 1 axle gears and 4.25 to 1 compression pistons is an increase of 104 per cent at 60 m.p.h.; 163 per cent at 30 m.p.h., and 199 per cent increase in miles per gallon at 10 m.p.h. **These figures certainly are emphatic enough to arouse several changes in viewpoint of our present methods of applying our engines. Evidently there is room for very considerable progress and it is hoped it will be forthcoming in the near future.**

Means should be developed making it possible to use very high piston compression ratios. It seems certain that it can be done and to great advantage in increased economy. It is hoped that very decided progress will be attempted in piston development with a view to overcoming knocking and increasing the general efficiency.

As engines are made smaller to increase the load factor, carbureters will be made larger to avoid pumping losses and loss of maximum power. The fallacy that large carbureters are not as flexible or as economical as small ones is based, it seems, on the failure of certain types of large carbureters which it is thought are working on incorrect principles. **It is recommended that we try the plan of using large carbureters to operate small engines, rather than using large engines to operate small carbureters.**

The possibility of securing higher mechanical efficiency should be studied from every angle. The tests show that an absurd waste is rampant in our present method. How far our ingenuity can go in this direction is hard to predict. **One thing is certain, we must analyze carefully the gains that can be made. A close study from the brake-horsepower standpoint may justify changing both our transmission and our rear-axle drives. The latter combinations, together with engine developments, look the most promising at present. The progress we make undoubtedly will be measured by the extent to which we expand our engineering viewpoint.**

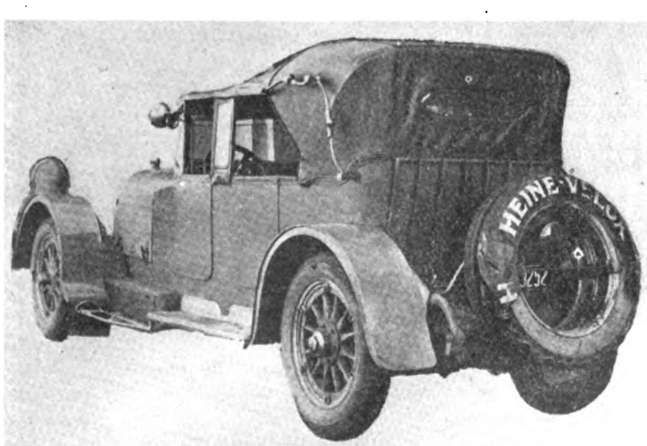
New High-Priced Twelve

A NEW high-priced car, the Heine-Velox, is announced from the Pacific Coast, the manufacturer being the Heine-Velox Engineering Co. One of the chief aims in the design of this car was to combine a low center of gravity with a fair road clearance, to insure easy riding qualities, freedom from skidding tendencies and long tire life. The car has a 148-in. wheelbase and can turn in a 53-ft. circle. The floor of the car is only between 22 and 23 in. from the ground where the car is loaded, and the drive from transmission to rear axle is then straight.

The engine has 12 cylinders, and is built partly by the Heine-Velox Engineering Co. from parts supplied by the Weidely Motors Co. It is said to be the same type as used on the H. A. L. car. One of the power plant features is an oil cooler, a desirable asset for a car used in mountainous districts. The weight of the sport model illustrated is 4500 lb. The oil level gage is in plain view of the driver. The windshield is of the clear vision type, without supports to obstruct the driver's view. The body is hung from the sides of the frame, instead of being suspended above it, and the floor is entirely inside the frame, making the top of the frame channels level with the top of the floor. The radiator front is in line with the rear side of the front axle. Four hydraulic brakes are fitted.

The instrument board and the brake and gear levers are placed in an unusual position, so that the driver can reach any part without inconvenience from his seat. The following instruments are used: oil pressure and oil level gages, Radi-meter, speedometer, clock, gasograph, ammeter, voltmeter, battery gage and altimeter.

This car will be furnished as a sport model, limousine sedan and racing runabout. The standard models sell at up to $17,000, and special models at up to $25,000. All bodies will be custom built in the Heine-Velox plant.



The Heine-Velox twelve with sporting type body

Muck-Raking in Demand

IT appears that the Danish Government has had the military flying service investigated by a committee appointed for the purpose, and that the latter is about to issue its report, concerning which some information has leaked out in advance. According to *Swensk Motortidning* the report will unequivocally condemn the whole service, which is declared to be uunworthy of any consideration. One of the first steps taken was to forbid the use of all military aeronautic material, comprising about twenty planes, and the Commission announced that all the equipment would be destroyed, notwithstanding the fact that much of it has never been used. Severe criticism is also passed upon the construction of a flying field and the training of military fliers, which is regarded as quite inadequate.

What Place Has Individual Personality in Industrial Relationships?

It is often said of plants where excellent industrial relations have been obtained, "It all depends upon the personality of Mr. Smith; if he were to die, they would have as much trouble as anybody." This article discusses the various sides of the question, and presents helpful conclusions.

By Norman G. Shidle

THE industrial relations story of many plants has been written. Very often a successful achievement along this line seems to revolve almost entirely about the personality of a single individual. In such cases a study of the particular story may yield but meager material for adaptation in other plants. Remove that individual and nothing may be left to the industrial relations policy of that firm.

In the Endicott-Johnson shoe factory, for instance, if consensus of journalistic opinion is to be believed, the success of the industrial relations policy revolves chiefly about the lovable personality of Mr. Johnson. Remove that personality, and there is but little story to write. Saying that if the individual is removed in such a case nothing is left of the industrial relations policy, is not to say, however, that the policy would necessarily fall to the ground immediately he was removed. It might—but it might not. It is this question that calls for further discussion.

Because personality has played such an important part in the success or failure of a number of plant labor relationships, a thorough analysis of that factor will be of value. It must be recognized, and it might as well be analyzed and estimated at its true value.

Various plans for employees' representation and industrial democracy have been formulated and advocated for use in any plant. Such plans, however, must be administered; a personal contact must occur somewhere along the line between employer and employee, whether such a plan is in effect or not—and again enters personality.

Even where mechanical means for organizing a labor policy have gone the farthest, the success of the plan rests largely upon how the administration is carried out, which in turn depends upon the composite or individual personality of the particular management.

The Greenfield Tap & Die Company, for instance, has had an industrial democracy plan in use for more than a year. It is working successfully. During that time the management has never yet exercised its power of veto on any recommendation made by the employees' representatives. Only three times has the management returned to the employees' representatives recommendations, asking that those representatives reconsider the recommendation. In each case the management has sent along with the request for reconsideration a full statement of its reasons for asking that the matter be discussed again. Each time that this has happened the employees' representatives have discussed the statement of the management and withdrawn the recommendation.

Note, however, that the management has the power of final veto; it could have simply vetoed these measures and that would have been the end of it. The method which it did use implies one sort of personality; the method that it could have used but did not, implies another sort. Had "the other sort" been in control the whole representation plan would probably have broken down before this. Personality, attitude of mind, habit of thought—whatever you may call it—plays a large part in industrial relationships whether in the person of a single individual or in that composite individual known to the workman as the management.

The constant and direct contact between management and employees, however, usually revolves to a large extent about one person; often the personnel manager. And it is through that man's personality that the management is reflected to the workmen. In the case of the Endicott-Johnson plant, it is through Mr. Johnson, according to reports. In the case of the White Motor Company, it is chiefly through one of the vice-presidents; in the case of the Filene store, through one of the vice-presidents; in the case of other companies through other individuals. The cases mentioned all involve companies which have been conspicuously successful in conducting the human relationships of their organizations.

The criticism of the policy of a plant which revolves so strongly around the personality of one man is that stated in the beginning of the article; if that man should die or be lost to the firm, the whole structure would topple over; it rests chiefly upon a personal adherence of the majority of employees to that one man. They love him, they respect him, they trust him, and admire him. If he goes, what becomes of the industrial relations policy?

The answer is fairly clear. It varies with different cases and may be divided in this way:

1. In some cases, the criticism given above is perfectly valid. The structure will fall to the ground when the particular personality leaves, because it has not only grown up around that personal adherence to an individual, but it is carried on upon the same basis.
2. In other cases, the man with this personality was necessary to start the work in the beginning. Perhaps the confidence and trust of the men has been built up on that basis. When that has been done, however, this man has been able to instil the same spirit throughout the management and executive organization until finally the composite "management" becomes an attractive and trustworthy personality to the employees. In such cases the work can be carried on without any diminution of success after the individual leaves.

(Continued on page 179)

Distributing Overhead Expense by the Machine Hour Rate Method

After describing briefly the four other methods of distributing overhead expense, Mr. Haigh shows in detail the advantages of the machine hour rate method. He believes that more knowledge of the expense element of manufacturing cost is obtained by this method than any other.

By Christopher Haigh*

An interesting discussion of the methods of distributing overhead expense, with particular reference to the advantages of the machine hour rate method, is contained in the following paper presented before the American Gear Manufacturers' Association by Christopher Haigh, Supervisor of Costs, General Electric Co.:

There are five methods in general use for distributing overhead expenses. These are:

Man Rate
Man hour
Sold hour
Material and Labor
Machine Hour Rate

The man rate method is the one in most general use, because of its simplicity. To use this method, it is only necessary to find the ratio of total expenses to total labor for a given business and to apply this ratio to the labor cost of each job. For a factory making one kind of product, this method of distributing overhead is quite satisfactory, but where the product itself is varied and the tools used in getting out the product are different for each of the various units produced, it is incorrect and misleading as to final results. There is no more justification for considering that one dollar's worth of labor actually applied to the product should always take the same percentage of expense than there is for the assumption that a lathe and a boring mill, which cost the same, are operated for the same amount and occupy the same floor space, or, further, that the overhead cost of maintaining benches and assembly floors is the same as the overhead cost of maintaining and operating machinery.

Defects in New Rate System

This method of applying overhead also assumes that the highest paid workman requires the most overhead expense, when actually the lowest paid man often requires the most supervision, and frequently the machine tools used by the low priced man are more expensive and require greater expenditures for operation and maintenance than those used by the skilled mechanic, because we incorporate in the machine which enables us to use lower grade labor the skill which the high grade man has in himself. Thus, if we design a semi-automatic machine for making any part, we can use a man who is not an expert mechanic to run this machine, or even several of these machines, but if we did not have this special equipment, we would require a skilled man in constant attendance on a more simple machine. It is obvious in this case that the overhead expense which is incurred in running the automatic machines is much greater in proportion to the wages paid the operator of these automatic machines than is the overhead incurred in running the mechanical equipment required by the skilled mechanic.

It is also true that even if the same wages were paid all men in a manufacturing establishment, it would still be wrong to apply the overhead to each job on the basis of a percentage to labor, for we would still have the condition of one man running more machines than another and of the difference in cost of the machines operated; also, that some men would be occupied on jobs such as cleaning castings, checking finished product, painting, etc., which require little mechanical equipment, and therefore do not increase the overhead expense at the same rate as their wages increase the direct labor payroll.

From the foregoing remarks, it would appear that the man-hour rate method of distributing expenses is a very dangerous one and that all manufacturers who use this method are certain of losing money. Therefore, it seems to be necessary for me to say a few words showing where this method may give results which will be satisfactory from a standpoint of profit.

When Equipment Is Standardized

In a manufacturing establishment where the mechanical equipment is fairly well standardized, where the products, while varied as to different types, still have the same average types of output, and where these types all require substantially the same machining operations; it will be found that the ratio of profit to total output will come up to expectations when the man rate method of distributing overhead is used. There is also a factor which must not be overlooked when considering any business, and that is, the amount of information which the man or men at the head of it have of that business independent of records, as I have frequently found that when estimating cost of new work, allowances are made by the owner of the business for a higher expected cost of the new work due to special facilities which will be necessary and to the expectations that the bigger machines in the plant will be used on the work. By making such allowances, the final price submitted includes some of the factors of expense cost which are not actually subject to proof from any records of overhead expense which would be available if the man rate of distributing overhead were in use, but which nevertheless result in the inclusion of these extra items of expense in the selling price.

There is, however, a question in my mind, and I think in yours, as to how many men who manufacture a wide variety of gears can give the necessary weight to all the expense factors which will increase or decrease the cost of

* Paper read before American Gear Manufacturers' Association.

a particular kind of gear, and it is undoubtedly true that many of the manufacturers who are making good profits on their total business are losing money on some particular type gear because of their lack of knowledge of the operating cost of their machines. Also that they turn down business on which there may be good profit because their selling price is figured on the basis of the average overhead which brings the price up higher than the buyer will pay.

The Man-Hour Method

The man-hour method of distributing overhead has for its base the number of hours spent on a job instead of the amount of wages paid. This method is subject to the same criticism as the man-rate method in that the assumption is made that the overhead expenses have a fixed ratio to the number of hours of time spent on a job. The advocates of this method point out that certain items of expense do bear a direct relation to the number of hours worked, and include under this head the expenses of the payroll and welfare departments, toilet articles, compensation, insurance and supervision, and we can agree that to a certain extent these items bear a closer relation to hours worked than to wages paid, but as these items are a small part of the total expense, and as it would be erroneous to distribute the major part of the overhead on this basis, I see no advantage in this method over the man-hour basis. Moreover, it can be pointed out that we do not reduce our payroll and supervisory force every time business falls off to such a point that we lay off some of the men, and therefore, the cost per man-hour of operating these departments would fluctuate sufficiently to nullify any advantage gained over the man-rate method, particularly where this advantage consists mostly in compensating for the difference in labor rates by substituting hours worked for wages paid.

Material and Labor (Prime Cost) Basis

The application of overhead on the basis of prime cost (material and labor) is not in very general use so far as I am aware. This method requires that the total expenses of a business be divided by the sum of the direct labor and direct material, and that the ratio or percentage so obtained be applied to the direct material and labor cost of each job turned out. It is manifestly wrong to apply this method to the product of a business which uses various kinds of material, but, where the product is all made from iron or steel, this method has some good points, as, by taking the material into consideration as well as the labor, we apply more accurately the expense of handling the material in the shop which, of course, varies with the size of the piece handled. In a shop using both copper and iron castings, this method would be worse than the two previous ones, as by adding the value of a copper casting to the labor of machining it, we would get a total figure which would carry a very high amount of expense which, when compared with the expense cost applied to an iron casting of identical size requiring about the same amount of labor, would indicate that the expense cost of machining the copper casting was as much higher than that of the iron casting as the difference in the price per pound of copper and iron.

This method has many of the same kind of inherent defects as the man-rate and man-hour methods, as we would still be applying an average expense to jobs instead of an actual cost, the difference between this and the other two systems being only that the material is added to the labor before determining the expense to be applied.

Even were this method the correct method for some businesses, the places where it could be applied are limited in number, and this method can never be applied generally. It is mentioned here, however, as it has been pointed out to me that the steel gear business is one of the very few where this system could be applied, and while I do not advocate its use, as I see very little, if any, advantage over the man-rate method, nevertheless, I think it well worth while to mention the system in connection with other methods of overhead distribution.

The Sold Hour Plan

The sold hour plan of distributing expenses provides that we take the total direct labor wages in a department and divide this total by the number of hours worked in the same period to get a flat average cost per hour for labor.

The time in hours consumed on any job is valued at this flat rate per hour, and the result is called the direct labor cost.

The expense is applied on the man-hour method previously mentioned.

This method is not in very general use and little can be said in its favor. The man-hour method of distributing expenses has been criticized before and much need be said regarding the determination of labor costs under this plan unless the rates paid workmen were practically uniform, we would include still another error in our final cost by using an average rate per hour for labor.

There are still other methods of distributing overhead for special businesses, but because of their limited application, no mention is made here. I have written about the four methods covered so far in this paper to enable me to show the contrast between the results obtained under these methods and the results obtained by using the machine hour method, which follows:

The Machine Hour Rate Method

This method consists of distributing all the manufacturing expenses of an establishment by a charge of each job of the overhead cost of operating the machines and other facilities used on that job. This overhead charge is not an average charge for the whole plant or department, but is, as nearly as possible, the actual overhead cost of maintaining and operating each of the machines, group of machines, benches, etc., which are found in the plant. By the proper use of this method it is possible to show the difference between the expense cost of a boring still and a lathe, a gear cutter and a splining machine, etc.

The advantages of this system are well covered in several books written by A. Hamilton Church, and I think it would be of benefit to those of you who have not seen these books if you would obtain a copy, as in this paper I cannot go into all the details of the system, nor do I think you would want to listen to an explanation of details even if the time permitted, and yet, to thoroughly appreciate the advantages of the system or to realize its disadvantages, a fairly complete knowledge is necessary.

Method of Determining Rate

To install a Machine Rate Method, we would first find the number of feet of productive floor space available for manufacture, eliminating the space used for foremen's offices, stairways, wash rooms, etc. We would use the number of square feet so obtained as a divisor for determining the cost per square foot per year for maintenance, depreciation, taxes, insurance and other kindred charges applying against the land and building. We would not include any expenses in this group which were incident to the actual operation of the machines, but only those charges which applied against the empty buildings ready for manufacture. We would include, however, the expense of lighting and heating and building and charges of a similar character. In this way we get a charge per square foot which is practically the same charge which the owner of

the building would make if he rented it to us and furnished the light, heat and water used in the building, except that he would require a profit on his investment which we would forego in the expectation of making this profit on the gears which we manufactured.

Factory Divided Into Production Centers

We would next divide the factory into production centers, including in each center machines of similar character located together, or individual machines where there were no convenient groups. We would never include different kinds of machines in one production center, as this would defeat the object of this system. After the division into production centers has been made, we would determine the number of square feet occupied by each center, including in this area the space required for the material waiting to go on the machines, the space required for the workman, etc., and would charge each center with a part of the rental of the whole building based upon the area occupied. This division would give us the rent per year for each production center, and in this way we would allocate the total charges of the building which we have called rental charges to various production centers. We have now got one part of our expenses divided in such a way that we can include them as one factor in the machine hour rate.

We would next determine the actual cost of the expense items incident to the operation and maintenance of each of the production centers. These expenses consist of depreciation of the machinery and equipment, taxes, repairs, small tools, cutting oils and other charges which can be definitely allocated to the one or more machines which have been included in one production center. If a small group of machines, all included in one center, require the entire time of one foreman, the wages paid this foreman would be included with the other expenses in arriving at the total cost of operating the center.

The distribution of the power charge can best be made on the basis of the horsepower required by each production center. In this power charge we would include the expense of running the power plant as well as the shafting, belting, etc.

The expenses which we are dividing should cover a period long enough to insure correct results, and should cover a period of normal operations so that our results will represent the hourly cost of operating our production centers in normal times and under normal conditions. The best results are obtained if the expenses for a whole year are used as a basis for the machine hour rate, and if these expenses are carefully analyzed and allocated to the various production centers, the hourly rates first determined will not require much adjustment. In fact, the success or failure of the system depends on the amount of attention given to the division of the expenses at the start, as, unless the first rates are approximately correct, the first results obtained from the system will be so disappointing and misleading as to cause a manufacturer to condemn it and to insist for all time that the plan is no good.

A Detailed Analysis

For the purposes of this paper, we will assume that the expenses analyzed cover a period of one year.

We have now divided two groups of the annual expense among the various production centers, and by adding the rental charges and the charges for operating and maintaining the machines, we have the basis for determining the hourly cost of expense applicable to work on the Machine Hour basis. To determine the hourly charge, we must estimate the total normal hours which each production center will work per year; we then divide the amount of the expenses allocated to each production center by the normal hours this center should operate, and the result is an expense cost per hour.

There still remain a few items of expense which have not been distributed, such as supervision, clerical and general administrative expenses. These expenses should be totaled, and this total divided by the sum of the normal hours of all the production centers. The result of this is another hourly expense cost which is to be added to each machine rate as a supplementary charge.

It must be brought to your attention that the machine hour rate is based entirely on the assumption that the production centers will work a certain number of hours in a certain time—a year having been used as the basis of this discussion. It is obvious to all of us that no man can predetermine accurately the number of hours any machine in his plant will be occupied, and many people reject the idea of installing this system for that reason alone. I think you will agree, however, that either by keeping records, or examining records already available, a close approximation of the normal working time of any machine can be found, and if the expenses of operating the machine are based on an approximately correct operating time, we have, by the machine hour rate method, a means of showing immediately the financial effect of any variation of the operating time of the machines from the predetermined normal or standard operating time.

In making up the hourly rates, we assumed that we had a certain amount of expenses, say $1200, to absorb in a certain period, say one year, over one production center. Let us say that we estimated that the normal hours that this center would be used in the year were 2400, or 200 per month. On this basis, the hourly expense cost operating this production center is fifty cents. By adding fifty cents for each hour that a job required the facilities of this production center, we would expect to absorb all the expenses connected with it. Now, if the jobs passing through this center in a month required the use of the facilities for only 180 hours, we would see at the end of the month that on this particular center we had failed to absorb $10 of our expenses. We would have the same information for all other centers and, therefore, for the whole shop, and would know at the end of the month how much of the manufacturing facilities had not been used or had been used more than we expected, this information being available both in terms of hours and money.

Supplementary Rates

It is not, of course, expected that any manufacturer would absorb all of the differences between the amount of expense actually absorbed and the amount which he expected to absorb, and to insure that all expenses are included in cost, a supplementary charge is made to each job to liquidate the amount of expenses which has not actually been absorbed through the machine rate in use.

This supplementary rate is a part of this system of expense distribution and is, in fact, a valuable factor because we know from the amount which we add to cost to absorb these supplemental charges, how far from normal the plant is running. In fact, one of the great benefits of this system is that the supplementary rate soon shows if machines are idle because the expenses which would be absorbed by machines which had work to do become, when these machines are not in use, a part of the supplementary charges, and the fluctuations in the monthly amounts liquidated by means of this charge show to a great extent the efficiency with which the facilities of the plant are being used.

It will be evident to you, if I have been successful in showing you how the manufacturing expenses of a business are distributed by means of the machine hour rate,

that this method allows of a very close knowledge and control of overhead expenses, and that by this system we can obtain actual costs of each job.

When comparing the way in which expenses are distributed through the use of machine rate costs with the distribution by means of any other method, it will be seen that, as far as accuracy is concerned, everything is in favor of the machine rate method. In fact, I think the claims of its advocates, that this method is the only safe and scientific way of expense distribution, must be allowed. All other methods of absorbing manufacturing expenses depend in one way or another on averages, and yet there is no more reason for averaging the expenses over costs of all the work produced than there is for averaging the material items.

I mentioned at the beginning of this paper that I was opposed to the application of any system to a manufacturing business which did not result in an increased knowledge of that business, and, through this increased knowledge, to a certainty of profits. I think that no one can, or desires, to refute the statement that more knowledge is obtained of the expense element of the manufacturing cost through the machine hour rate method than can possibly be obtained through any of the other methods used in business.

I am sure you will also agree that any of you who has this knowledge would use it to determine what business to take and what to refuse. If you were given the opportunity to bid on an inquiry for gears which would require your biggest machines, you would certainly make your price such that your expected profit would actually be profit on that particular job, and would include in the cost on which this profit was based the actual overhead expense of the mechanical equipment to be used. If your price, assuming that your profit was reasonable, was such that you lost the order to some one who was quoting a price based on an average overhead, you would feel perfectly sure that this other concern was taking business at a loss and would be willing to let them have the order. Conversely, there are many jobs which require less machinery and cheaper equipment, and your method of arriving at costs would allow you to take this kind of business at a price lower than the concern whose costs were not accurately determined.

I believe that the reason this machine rate method is not in more general use is because of the amount of work which is required in getting the system working, and the extra bookkeeping involved in keeping the records which must be available if this plan is followed. Most manufacturers have an objection to increasing the administrative expense of their business and would rather spend money for new machinery than for a system of records. This attitude is certainly correct if there is no doubt that the business as run without these records brings satisfactory profits and will continue to do so, and if the new machinery earns its keep, but in any business which is to any large extent competitive, the need for accurate records will sooner or later be felt, and I am firmly convinced that those concerns which have the best system of cost records will be in existence long after the manufacturer who figures his cost on the hit or miss method has gone out of business.

Sufficient Spare Parts a Necessary Feature of Proper Tractor Service

(Utilitor Service System)

"A TRIP through a prosperous Eastern agricultural section shows that tractors are being bought. There is little indication, however, that they are being *sold*," writes Donald Blanchard in a recent issue of *Motor World*. And again, "Service sells satisfaction and satisfaction sells tractors." The vast importance of proper service as an adjunct to sound tractor merchandising is becoming more widely recognized among tractor manufacturers every day.

In the case of any particular tractor there is, within certain limits, a comparatively fixed number of parts which it is highly desirable for the dealer to carry in proportion to the number of tractors to be serviced in his territory, in order to render rapid and efficient service, while still investing in parts the minimum amount of money.

The dealer is not always willing or able to take the trouble necessary to determine in a scientific way just what his approximate inventory should be. Because it is to the manufacturer's advantage that the dealer should have such an efficient inventory, however, many tractor manufacturers have studied the matter carefully and are giving their dealers the benefit of their investigations; in some cases even requiring that a certain fixed supply of parts be sold to the dealer with each tractor that he orders.

The Midwest Engine Company, manufacturers of a very small tractor, the Utilitor, is paying particular attention to the service features of its merchandising policy, and has developed some excellent practice along this line.

When a new distributer is signed, a letter is immediately written to him by the service director for the purpose of making his acquaintance, outlining to him the service ideals of the company, and welcoming him to the organization. Particular care is used to impress upon the distributer the necessity for carefully inspecting the tractor before he ships it to a dealer.

The number of each of the various spare parts necessary to properly service any given number of machines has been carefully worked out. Every distributer and dealer is required to accept a certain quota of spare parts with each machine.

The quota is so worked out that when a distributer or dealer has received three carloads—or 90 machines—he has on hand a small stock of each part which goes with the machine. With the first group of machines go those parts which are likely to need replacement soonest. When 90 machines have been received by the distributer or dealer, however, he has a sufficient variety of parts to build an entirely new tractor.

The allotments for these quotas have been made up by the factory service department on the basis of field data and a long series of careful experiments. The manufacturer requires that the stated quota of parts goes forward with each order of machines, and distributers are required to make a like demand on the dealers.

In this way the factory is certain that from the standpoint of spare parts, at least, adequate service can be rendered to every user of its product.

What Has the Manufacturer Done to Disturb Dealers?

History is of value only as it supplies a background for the making or unmaking of precedents. This article deals with two closed incidents—the allotments of cars and "drive-aways." These incidents are important only as they indicate whether the manufacturer profited in the long run.

By Clyde Jennings

THIS article must be read as a sequel to the article printed in Automotive Industries for Jan. 6. In that article it was established, by testimony of dealers themselves, that discontent exists. In this article we set forth some of the reasons for this discontent. Of course there are other reasons, some of them being much more serious. Later we will have something to say about the always interesting and important factor of contracts.

WE believe that it was fairly well established in a previous article that there is some existing discontent in the ranks of the dealers. In fact, we do not believe that any one will contend very strongly to-day that the automobile sales family is entirely harmonious.

It would be interesting, no doubt, to know just why this state of affairs exists. Perhaps you will recall that in the statements from dealers which were printed in the previous article that one dealer—No. 11—mentioned the fact that there was a charge of $15 a car for national advertising that the dealer was compelled to pass on to the buyer. That is one indication as to the direction of the wind that blows on the coals of discontent.

But last spring we were hearing much about the allotment of cars. We don't hear so much about this now, but how do the dealers feel about it? This was one of the questions put to a list of dealers by a man who is on the closest terms of friendship with them. Thirteen dealers answered and—

> **Not a single one of the thirteen defended the factory, without reservation.**

Do you get that? Not a single YES to the question:

> **Have the factories played square in the allotment of cars?**

We are passing on to you some of the answers. Not all of them will be printed, for they get just a bit monotonous. Some of each shading will do. The first three are especially severe (on the manufacturer). If I was a manufacturer and one of my big distributers would say these things about me, I would be inclined to worry somewhat. Read them and see what you think:

—

1—No, they have not. A good many factories have men high up who have stock in distributing agencies and they have furnished these agencies cars first. Then distributers on the ground got next preference. We distributers without a pull who stayed at home got only what was left.

—

2—Our factory, I know, has not played square in the allotment of cars. Some of the larger distributers have received freight shipments when other distributers have had to drive their cars all last winter and this spring.

—

3—The factories have not played square in the allotment of cars.

—

Here are several of the moderate answers. The details of these answers are so much alike that some have been shortened somewhat, but the wording of the part passed along has not been changed. These answers are interesting:

—

4—Factories have played square only so far as they got full payment for their goods at factory door or could readily obtain equipment for shipping.

—

5—As far as I can find out, our factory has given as cars pro rata to the number they manufacture, but we have always been very suspicious. I know of numerous dealers and distributers who have got very rotten deals along this line.

—

6—Our factory has played square with us and the dealer on the ground with the money has not been shown preference. I have reason to believe, though, that some distributers have not been so well favored and that preference has been shown in some instances.

—

7—The live-wire distributers who have had drive-away crews at the factories with instructions to take the cars as they came out of the doors and drive them away naturally have been favored.

—

8—I do not believe that all of the factories have played quite fairly in the allotment of cars. It is a fact that some of these factories have shown a decided preference to the dealer who was on the ground with sufficient money to take the cars and drive them away.

—

The previous article said that the dealers quoted are among the very best. Here is the proof of that statement. These dealers come in the class of "live wire"

business men, and, of course, they were the men who had men at the factory doors with money. In the following replies it is interesting to see how they justify this distribution.

—

9—Factories have not done in all instances what they should have done. We assume that they have done what most of us do—have taken the line of least resistance. There is no question in my mind but what a great majority of the factories have given preference to the man who has camped on the factory doorstep with the cash in his pocket when deliveries were bad.

—

10—As a general rule, it is my belief that the factories have endeavored to play fairly with the distributers and dealers. In answering this question it is, of course, necessary to take into consideration that we are all human and the factories, undoubtedly, to some extent like ourselves, the distributers, have given some consideration to the man who has been persistent to the point where we have, in some cases, given him automobiles to relieve his pressure. No doubt, the factories have in some cases done likewise.

—

11—Generally speaking, our factory has been very fair with us on monthly schedules, our increase this year being at a greater proportion than past showing would entitle us to. As to the day-by-day deliveries, however, I have known of some instances, personally, where dealers and distributers got cars to which they were not entitled. Also, nearly every time that Mr. Blank has gone to the factory he has succeeded in getting cars, whereas it was impossible to get them by correspondence.

—

12—I believe on the whole that the factories have been square in allotting cars to their dealers. The trouble with that lies in the fact that some of the largest distributers such as New York, Cleveland, Chicago and so forth, have been allotted larger proportionate contract allotments than the smaller points.

—

There is just one more reply that will be quoted. This man is very careful to speak for his factory only. It is the only real defense of a factory noted in the correspondence that is being quoted:

> **In so far as our company is concerned, I can truthfully say that in my opinion the factories have been absolutely square with us in relation to allotment and I do not believe that any other distributer with ever so much more money than we may have and by virtue of being on the factory doorstep can get any more cars than we can. Our factories have sold me on the fact that they are treating us all right.**

If I was an automotive manufacturer I would insist that this dealer remain in my organization.

—

We all know that one swallow does not make a summer, and that one point of discontent would not make for a seriously discontented dealer world. Last winter and spring we were hearing a good deal about freight charges and drive-aways. As this is to a large extent a closed incident, we thought it would be interesting to sound out the dealers and hear how they felt about it. If one can judge by the general tenor of the following replies, some of the dealers are inclined to be a bit sore on this question. Some of the dealers are located so far from the factories that drive-aways did not enter into their operations, but nearly all replied to the question directly. The question was:

In view of drive-aways, factories were not put to the expense of loading, blocking, etc. Was there any dealer credit allowance made as a consequence thereof?

—

1—Some of the factories have more than offset this by putting the cars in proper condition and filling the tanks with gasoline. This has been true with the Blank people, for instance. Other factories have made a common practice of doing nothing and putting in a small amount of gasoline, probably five gallons, and letting the dealers shift for themselves. These factories, therefore, have saved a great deal of money for themselves by so doing which, of course, is an injustice.

—

2—Factories have never made any credit allowance for drive-aways.

—

3—Factories have made no allowances on drive-aways. Have grabbed the money and paid no part of shipping expense away from factory—supplied no blocking and made no allowance.

—

4—The manufacturer has been giving the dealer enough gasoline to take him to the first filling station and it would insult him if you asked him for any credit allowance because he had to do no loading or blocking.

—

5—No factory has, so far as I know, made any allowance or credit for the money they saved in loading or blocking cars.

—

6—So far as my knowledge extends, no factory has made any allowance to distributers for driving, loading or blocking.

—

7—The factories have not made allowances to the dealer wherein they saved the expense of bolting, blocking and so forth on drive-aways.

—

8—No allowances have been made in the case of drive-aways, so far as I know.

—

9—Our factory has not made an allowance of five cents for drive-aways although it has saved thousands of dollars in blocking material and labor charges. They have made in return a fixed charge of so much per car for getting cars ready for drive-away. In other words, they have added on an additional profit for themselves.

—

10—We are charged for decking for each car as shipped at a fixed rate. No charge of this kind is made on drive-aways. Of course, no allowance is made but none would be coming if the charge is actual cost.

—

11—We have never received any credits from our factories in lieu of loading expense on drive-aways. Two of our factories furnish a liberal supply of gasoline and have the motors completely filled with oil. The third factory makes a small drive-away charge. I believe that cars made ready for drive-aways have to be a little more completely equipped and inspected than for shipping, and it has been my thought that the cost of loading saved in drive-aways was pretty well absorbed by the additional work necessary to get cars ready to drive them away.

—

There is one fine thing about the answers to this question. That is the unanimity of opinion, and the short, sharp method of expression. Some of these answers fairly cut. The manufacturer can hardly be in doubt as to the impression left on the distributers' minds by this incident.

Bureau of Standards Annual Report Shows Extent of Automotive Research

Growing importance of the Bureau's activities to the automotive industry made apparent. Work includes research on carbureter and vaporization problems, materials of construction, storage batteries, spark plugs, etc. Much progress made in improving methods for testing lubricants.

IN the annual report of the Bureau of Standards, recently issed there is given an outline of the research work on problems connected with the design and operation of internal combustion engines which the Bureau has completed or has in contemplation. The variety of work done of an automotive character shows the growing importance of this Government bureau to the automotive industry.

According to Dr. Stratton, specifications for starting and lighting batteries have been prepared, at the request of the Motor Transport Corps. The effects of various factors on the voltage required to produce a spark at the terminals of various types of spark plugs under operating conditions have been determined. The results of this work are of special importance in providing for reliable ignition on engines operating at high altitudes with a supercharger.

A special research was undertaken to determine definitely the cause of occasional failures of ignition in aircraft engines apparently due to faulty spark plugs. The results were to demonstrate conclusively that early ignition of the cylinder charge due to overheated spark plug terminal was the cause. Types of construction which tend to aggravate or to prevent this effect were determined. The cylinder pressures resulting from such preignition were also shown to be some three times normal pressures and to constitute an enormous accidental overload on the engine parts.

The Bureau of Standards makes it clear that its researches into antifreeze solutions for automobile radiators are necessarily incomplete, but so far none of the materials submitted warrants the recommendation of solutions other than alcohol and water.

The laboratory for research on carbureter problems has been used for tests of a number of carbureters, including the following: White Co., Browne, Mitler, German Zenith (from German motor truck) U. & J.

A mathematical analysis of the laws of flow involved in one method of compensating for the effects of change in air density at altitude has been completed. Similar analyses of other methods are required.

The fuel economy and power of an internal combustion engine depend upon the condition of the mixture as regards temperature, vaporization of fuel, degree of mixing, etc. An investigation of this problem has been in progress.

Essential to this investigation is a knowledge of the vapor pressures and vapor volumes of the customary fuels. Apparatus for measuring these quantities has been in use for some time and results have been obtained on a number of fuels.

The carburetion research has been undertaken mainly at the instance of the Air Service and of the National Advisory Committee for Aeronautics, but some features of it are of equal interest to the manufacturers and users of all types of automotive appliances.

The Motor Transport Corps has requested the Bureau to study the quality of the materials used in the construction of a large number of German motor trucks.

At the request of a maker of 6-throw automobile crank shafts the process of manufacture was studied with the idea of eliminating certain difficulties which had been encountered.

During the year physicial tests were made on 1,193 samples of oils and greases. This very large increase in work, as compared with previous years, was principally, if not entirely, due to the great number of samples received from the War Department.

The development of a lubrication laboratory with special reference to study of lubrication problems in automotive engines was begun in 1918, hence much of the time has been devoted so far to the development of apparatus and methods.

A series of tests were run in a typical aeronautic engine to determine, if possible, any difference in lubricating value of oils from different classes of crudes. The results showed no significant differences between properly refined oils from different sources, provided the oils are chosen with equal care to meet the conditions of operation.

A series of routine laboratory tests was run on samples of all trade-marked oils sold on the market and which could be secured by the Bureau. The results will serve as a guide to purchasers of oil and it is hoped will be of much value when published in the near future.

A new method of distillation has been perfected for the analysis of lubrication oils, which has proved to be of great value. By the use of superheated steam at very low pressures, in a special still, it is possible to fractionate ordinary lubricating oils and determine their composition with, in most cases, a negligible amount of decomposition. This process gives promise of important applications in the refining of oils.

Other problems which have been undertaken are (*a*) the relative effects on different classes of oils of dilution by fuels escaping into the crankcases of engines, (*b*) the extent to which fuel vapors are dissolved in different classes of oils. No significant differences between oils in these respects were found.

The tendency of oils to form so-called carbon deposits in engine cylinders has been investigated to some extent during the year. Further investigation of the oxidation test and the demulsibility test developed by the Bureau has been made in this connection.

Tests of 25 commercial brands of automobile oils were carried out in co-operation with one of the large automobile manufacturers. A number of special types of automobile oils were also tested for the inventions section of the War Department.

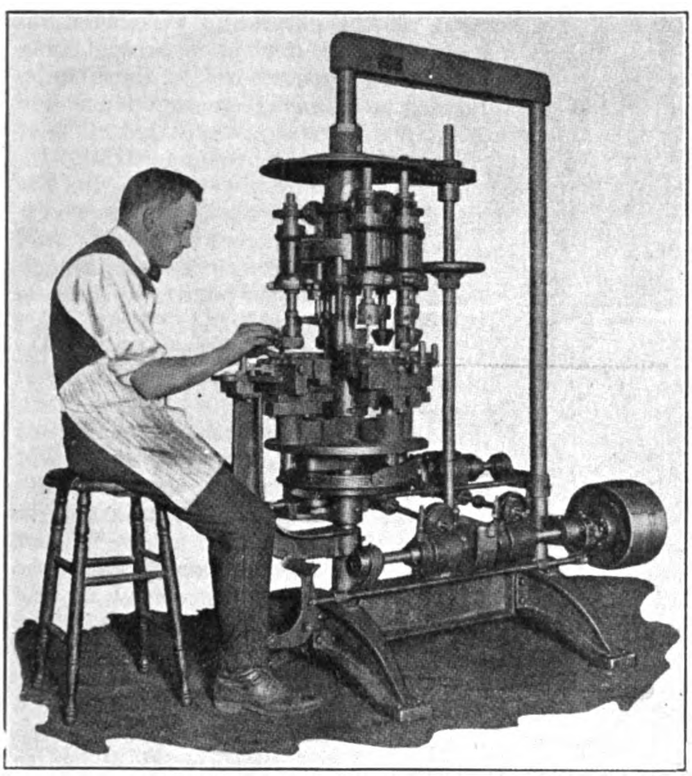
Owing to an unavoidable delay in the delivery of dynamometer equipment no progress was made in the investigation of power losses in tires. The apparatus which is now available will be used in a series of tests to be made in co-operation with the Motor Transport Corps and the Society of Automotive Engineers. A study will be made of different types of tires and of tire fillers under definite conditions of speed, load on tire, and power transmitted. The results of this research will be of particular interest to tire manufacturers in view of the necessity for reducing to a minimum the energy dissipated in tires, which often causes a rise of temperature sufficient to produce serious injury.

The Bureau has co-operated with the American Metric Association in recommending and promoting an international standardization of tire sizes. The importance of such standardization was brought out very clearly during the war, when it was found necessary to change the wheels on some of our motor cars in order to permit the use of tires manufactured abroad.

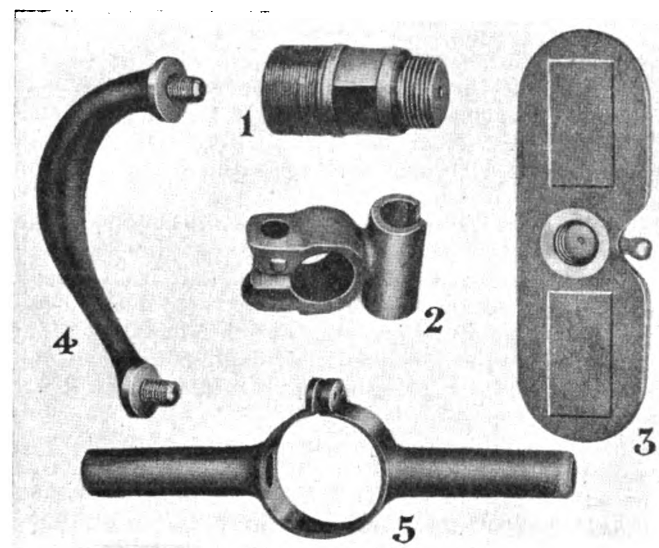
The Bureau has co-operated with the Air Service of the War Department in the development of specifications for leak-proof gasoline tanks and rubber shock absorbers, and in the production of a satisfactory rubberized silk fabric for diaphrams used in connection with autographic instruments.

A Vertical Automatic Chucking Machine

A VERTICAL automatic chucking machine with four duplex automatic chucking vises and three pairs of working spindles is being built by the Long Henkel Mfg. Co. The machine, known as Type B, is best adapted to work requiring (*a*) turning to size, (*b*) drilling or boring, (*c*) threading or tapping. It is claimed for this machine that it produces more work than other machines suitable for similar operations. The chucking vises automatically



Long Henkel vertical automatic chucking machine



Samples of work done by the chucking machine. Operations include turning, facing, drilling, threading and tapping. 1—Pump nipple. 2—Battery terminal. 3—Pump base. 4—Door handle. 5—Pump handle

eject the finished article, and after the operator puts the unfinished article in place, the vises again close automatically, thus relieving the operator of everything but the mere handling of the castings and observation of the work. The machine has positive drive and is equipped with ball bearings. All work is in full view of the operator.

The machine is not limited to simple operations. Multiple operations can in many cases be performed with the same setting, as, for instance, drilling different sized holes, tapping with different sized taps and various other operations limited only by the number of spindles that can be used. A magazine feed can be applied when the machine is used for threading or tapping bolts or nuts.

Individual Personality in Industrial Relationships

(*Continued from page* 171)

3. In still other cases, the whole structure of industrial relationships is built up from the beginning simply on a basis of fairness, honesty, and ordinary business goodwill between management and men. In such cases individual personality plays a small part.

Under any circumstances, however, the personality of the man who is to be the connecting link between management and men must have a personality that is attractive to the majority of the workmen. He must be able to sell himself to them. If he is not able to do this, he is not the man for the job, regardless of his other qualifications.

Personality may as well be recognized at the outset as a potent factor in the success or failure of an industrial relations policy. It does not do to discount it. On the other hand, it must not be depended upon to do the entire work. Other practical factors must be back of it.

And above all, sincere pleasing personality must never be confused with the "glad-hand." The former is a real diamond; the latter paste—and not even a very good imitation.

It Costs Less to Hold a Customer Than to Get a New One

Here is an unusual analysis which shows the importance to the manufacturer of the factory service manager and his policy. The general manager of a motor car factory asserts in this article that the service department has obligations and can be of great value to the factory.

By George C. Hubbs*

IF it were true in the early days of the horseless carriage that service men were obliged to think in terms of mechanics, it is equally true to-day that the highest grade service men are those who think in terms of personality.

This change of thought has been made possible by the tremendous strides which motor car engineers have made in car design and construction, and it has been made necessary by the fact that to-day, with over 8,000,000 cars in the hands of owners, there are probably from ten to twelve million drivers to be dealt with, each one presenting a more or less different and difficult problem in personality.

Perhaps it would not be putting it too strongly to say that the handling and repairing of the temperaments of owners or drivers has become quite as much of an art, and quite as necessary a part of a service man's equipment, as is the skill required to repair their cars.

If this is true, then a service manager of a motor car manufacturer finds himself occupying the new and exacting rôle of service educator to the trade with respect to matters of conduct, diplomacy and honorable dealing.

Inasmuch as the owner-clientele of most dealers is very much larger than the number of new purchasers in any one year, it is perfectly obvious that upon the service manager rests the major responsibility for re-orders, for no fact is better known in this business than this: That the probability that a motor car owner will rebuy the same make of car is almost exactly proportionate to the character of service received from the dealers' service departments.

No manufacturer can dodge the responsibility for doing this educational work—nor should he want to. Certainly if he is going to fix the general sales policies for his dealers (and every manufacturer properly considers this his prerogative), then he should also participate in the larger and more difficult task of establishing a uniform standard of service conduct in the service departments of his dealers.

It has always seemed to me that sales and service policies should have their source with the manufacturer, and that the manufacturer is in reality responsible for the satisfactory or unsatisfactory experience which the individual owner may have with the manufacturer's dealers wherever the owner may have occasion to need sales or service help.

I am disposed to go so far as to say that in my opinion the manufacturer's service manager is responsible for both the efficiency and the behavior of every service employee in a dealer's establishment.

Such supervision is distinctly a protecting measure in the interest of the manufacturer's future business, and as such is well worth all the effort and expense it involves. Entirely aside from its effect upon current business, no manufacturer can hope to create those indefinable, but invaluable, assets known as confidence and prestige, unless he fortifies himself against that class of service men who seem to think that brusqueness and incivility are evidences of super-competency. In the hands of such men, a manufacturer's good name—established through great pains—is in real jeopardy. And if so, then it is his clear obligation to forestall such danger by giving his service manager the utmost latitude in prosecuting his educational campaigns.

I have spent a good many hours talking with service men about the necessity of being gentlemen (and amiable ones) before they were mechanics.

This, I am fully aware, requires an immense amount of work, inasmuch as many mechanics are more competent to deal with the weaknesses of machines than with the weaknesses of men. Machines are at least amenable to reasonable treatment, which is more than can be said of some humans. **Nevertheless, these humans are the manufacturer's customers and it is the duty of the manufacturer to guarantee to them at least fair and courteous treatment.**

It should also be borne in mind that, in addition to the fact that the manufacturer receives ample compensation in reorders and prestige from well-cared-for owners, the information which properly organized service brings to the engineering department would, of itself, more than pay for the cost of intensive service supervision, which introduces the service manager in two additional rôles—that of assistant sales manager and of assistant chief engineer. (And it takes a broad-minded sales manager and an open-minded chief engineer to fully appreciate the possible value to both of them of a highly efficient service manager.)

The real fact is, the service manager is the only executive of a motor car company whose value to the organization increases in almost exact ratio to the number of cars in the field, but this usefulness can be measurably added to by maximum co-operation on the part of the sales and engineering staffs. The service department is (or should be) emphatically **the best business insurance policy any manufacturer can have.**

*General Manager Grant Motor Car Co. Paper read at meeting of Factory Service Managers' Division of N. A. C. C.

Whether the repeat orders for a car run to 25 or 75 per cent of any year's output is a matter of distinctly major importance; and it must be undeniable that the service manager, by his thoroughness, or lack of it—by his vision of himself as a mere "trouble-shooter" or as an educator—is in a position to determine this percentage more certainly than can the combined efforts of the sales and advertising departments.

Furthermore (and it is not unimportant), it costs less to hold a customer than it does to get one. Also, the influence of a friendly owner is more helpful than the comments of a dissatisfied ex-owner.

The future of the motor car industry now lies largely with those who already own cars, so that the competition of the future will more and more concern itself with comparative service, that is, until such a time as faulty human beings can build cars without incorporating in them their own frailties, and thereby make service managers unnecessary. If the truth must be told, cars are good in proportion to their ability to keep away from service departments, but so long as they are neither fault-proof nor fool-proof, the character of service their owners receive will continue to determine how generously any particular make will be purchased.

It seems to me that inasmuch as the value one receives for any given expenditure is, to the buyer, more important than the expenditure itself, it is very certain that the really efficient, educator type of service manager is going to play an increasingly important part in the motor car business of the future.

Relation of Size and Power to Airplane Speed

By A. Ludlow Clayden

THE results of the Pulitzer Trophy air contest at Mitchel Field teach a lesson which was learned long ago in automobile engineering that enormous engine power is not the main factor in obtaining speed.

The Verville Packard, which covered the course of about 132 miles in 44 min. 29 sec., has an engine of 2225 cu. in. and at the speed it was revolving must have developed not less than 550 hp. Yet the Thomas-Morse was only 2 min. 38 sec. slower though its Wright engine is of but 1125 cu. in. and developed not more than 330 hp.

Apart from the engine powers it should also be remembered that the Verville plane was designed with speed as the main object, while the Thomas-Morse is a standard army plane fixed up for maximum speed.

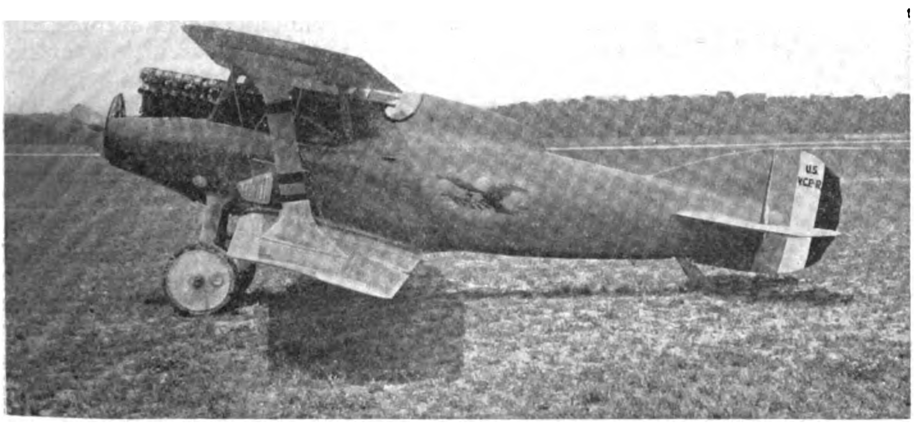
Even more interesting comparatively is the showing of the little Vought with only 718 cu. in. developing not more than 200 hp. in its Hispano-Suiza power plant. Its time was 11 min. 11 sec. longer than that of the winner or 25 per cent slower, with an engine less than one-third the size. Also the Vought ship is even less suitable for high speed than the Thomas-Morse.

Therefore, it seems reasonable to expect that by building as good a speed ship as the Verville Packard on a smaller scale, the performance of this plane might easily be equalled; just as automobile engineers found it actually easier to get high racing speeds from the 183 cu. in. engines than from the earlier 450 cu. in. engines.

In 1918 there was a prevalent opinion in France that the maximum speed combined with controlability would be found to require from 250 to 300 hp. That a larger engine, requiring a heavier, larger plane, would be less lively and so little faster that the extra speed would only count in running away. Hence the French concentration upon the 300 hp. Hispano and the British anxiety to develop the A. B. C.

So far aviation engineering has shown that there is a great lack of co-operation between engine and plane designers. For instance, when it is a case of using maximum power for speed or climb, nearly all planes are shown to have inadequate water and oil radiators.

For utter speed we have as the limiting load the weight and bulk of one man. Since there is only one resistance to consider, that of the atmosphere, it seems reasonable to expect that the most compact plane with the least bulky engine would be the easiest ideal for which to strive. And when we have it the small fast plane will be much more useful than the big fellow.



The Verville Packard biplane which won the Pulitzer trophy

Nickel Plating Aluminum

A PROCESS for nickelling aluminum is described in *Annales de Chimie Analytique* as follows: The aluminum is immersed for two minutes in a cold solution of ammonia and potassium cyanide. The metal is then well washed and brushed with milk of lime until the surface acquires an even, brilliant white tint. Then the washing and brushing are repeated with water, so as to get rid of all traces of lime, and the metal is immersed in an acid bath of manganese and iron chloride. A metallic coating of iron or manganese, which serves as the "mordant," as it were, to fix the nickel to the aluminum, forms upon the aluminum. After two to three minutes' immersion in the acid bath, the metal is rinsed with water and put in the nickelling bath, which consists of nickel sulphate. The anodes are plates of laminated nickel. The electric pressure used should lie between 2.5 and 3 volts, otherwise a non-adherent deposit would be obtained. The current density should be from 0.065 to 0.1 amp. per square inch (9.3-14 amperes per square foot). The treatment for moderate-sized objects lasts 1 to 1½ hr., and is followed by washing in boiling water and drying by compressed air.

A Review of the Present Labor Situation

The open shop movement is gaining momentum, the fear of unemployment has increased individual efficiency, and Americanization work has diminished. Interest in labor problems has diminished, visibility of discord governs attention to the matter. No permanent advance can be expected as long as this attitude toward the problems continues.

By Harry Tipper

AN examination of the conditions which prevailed in industry during 1920 indicates great changes in the visible symptoms of labor unrest, great changes in the economic position in various fields and a slowing down in the demand for increased wages, shorter hours and other matters which have been included always in the consideration of the labor union whenever opportunity afforded it a chance.

In the United States, the year has witnessed a decrease in the power of the American Federation of Labor, due to the differences existing within its own ranks as to the policies which should be pursued, and at the same time a decrease in the solidarity of other labor organizations very largely due to the economic condition and the amount of unemployment.

The latter part of the year also witnessed a very definite movement for the extension of the open shop, a movement which is apparently gaining strength in various industries and which may have some significance in connection with the whole industrial question as time goes on. Wages have been reduced in many industries, and in most cases where these reductions have occurred they have been more drastic than the reduction in the cost of living to the same workers.

Workers in the manufacturing industries have been obliged to take reduction on the position and the price which the manufacturer could secure, whereas the reduction in their cost of living represents only those reductions which the retailer has been obliged to make, and there has not been established as yet a parity between the reduction made by the manufacturers and the prices to the consumer.

With the increased efficiency and the increased unemployment, there has been a very considerable reduction in the labor turnover which in the early part of the year was very high.

For the moment in this country, the visible labor troubles are less in number and materially less in importance. Where the organizations of labor are very strong and complete in their control of the labor employed by an industry, the difference is not so marked. In some of these cases, in fact, wages are still being slightly increased and efficiency has not been increased materially. The situation, however, indicates that the advantage is once more on the side of the manufacturer in most lines of industry and that the fear of losing the job, which is always in the background, is playing an important part in the attitude of the worker of to-day.

The depression which exists in Europe has not had the same effect, at any rate to the same extent, because the political and economic problems are so involved that while there is a great deal of unemployment and suffering, the labor organizations are still intimately concerned with the political programs and their attitude is governed to a large extent by the political necessities with which they are concerned. There is no indication that the unrest in Europe has diminished materially, and there is no present evidence which should justify an expectation of this kind in the near future.

This country is placed in a so much more advantageous position economically, that the severe unemployment is not sufficient to cause the unrest which obtains in Europe, and the political situation does not enter into the industrial question to the same degree because there are no affiliations between industrial organizations and political parties.

From the manufacturers' standpoint the present condition offers at least a relief from the constant problem which he was facing in connection with labor matters until the early part of last year, and it offers also an interval of relief of which he can take advantage in building his organization along lines which will make it possible for him to evade some of the labor trouble in the future.

There is a tendency in some quarters to over emphasize the change in the situation and imagine that it has a permanent significance, just as there was a tendency to explain the previous condition by reference to the war. The reasons which are at the bottom of the lack of organization in this country among the workers are important elements in the consideration of any plans for the establishment of prominent bases of operating efficiency. The number of races involved in the working population of this country and the difference in their traditional, political and social inheritance and their understanding, makes it difficult for them to come together in any well-ordered organization and makes it just as difficult for the employer to bring them together in any well-determined unity.

The infusion of further new labor by immigration will not solve this problem, although it may provide a larger supply, and therefore, retain the advantage on the side of the manufacturer for some time. In effect, however, it will add to the complexity of the situation and increase the difficulties which already exist in arriving at any well-ordered plan of operating efficiency based upon some unity of progress.

While we are considerably removed from the European situation and our conditions are very different from those obtaining in Europe, we will not be able to escape the influence exerted by the political movements and economic developments over there, and in respect of some of our working races, these influences will be quite definite and important.

The Americanization work which was developed with great vigor by many industries during the war and after the Armistice, has suffered in interest during the last six months, and is not the subject of discussion to anything like the same extent. This is somewhat unfortunate as the development of a reasonable understanding of our political and social structure is of primary importance in arriving at some unity, with so many different races involved.

> **It is apparent that the attention which was being given to the whole question of human relations in industry has diminished considerably in the last few months. It is now confined largely to those who have made a conscious study of the matter and are interested in it as a primary necessity, and these number only a small proportion of the people who were interested some time ago.**
>
> **So long as the manufacturers proceed with their study of the matter and their attempts to provide a reasonable basis for its future consideration, the amount of public interest is not very important. It is referred to only because it is an indication of the interest taken in industrial circles and because it shows a general lessening of interest and not merely a decrease in the public attention to it.**

The lessened interests of the manufacturers is also shown by the diminution in new experiments to the point where they are hardly worth recording and the lessened interest in some of the experiments already started even in the establishments where the work has begun.

This whole situation in 1920 is an example of the way in which the visibility of discord governs our attention to the matter itself. In the early part of the year there was great activity in the discussion of human relations, a great deal of attention was paid to the experiments being conducted, the discussions which occurred and to the plans which were being developed.

> **In the latter part of the year this interest died down because the visible symptoms of the problem decreased until they were practically out of sight. No great permanent advance can be made so long as the interest in the question is governed by these visible considerations.**
>
> **Experiments are undertaken too lightly in times of labor stress and dropped too willingly when the visible difficulty has passed away for the moment.**

They are not based upon a sufficient examination in the first place, and they are not based upon sufficient conviction of their value to put them through the second period.

Fortunately, this is not true in all cases. Leaders in various industrial fields are still engaged in working this problem out by the gradual development of reasonable plans. The value of these plans will be more definitely established when they have survived the period of business depression and labor surplus in the same way that many of them survived the period of business activity and labor scarcity.

Office Manuals

AMONG the many minor factors which go toward making office personnel work effective the office manual serves a distinct purpose. Its value is chiefly as a means of immediate and systematic information for the incoming employee, but its effect is widely beneficial. Such a manual is often more effective in the office than in the shop, because the type of employee to which it goes in the former case is more likely to be really interested in the material it presents.

The object of publishing an office manual is practically the same everywhere. One firm states it in this way: "The purpose of this manual is to acquaint employees with the rules, regulations and policies of the company, and to serve as a practical working guide for new employees as well as a reference, to which experienced employees can turn when in doubt."

The longer a new employee takes to become familiar with the routine and workings of a new office, the more his hiring and breaking in is costing the firm. A well-made office manual will probably do more to make new employees feel at home quickly—especially in a large organization—than any other single factor. Such a publication will pay.

To be effective, however, it should be carefully written and edited. The preparation of such a manual is a job that need be done only once, and care should be taken in its preparation for it is worth doing well.

It should contain (1) office rules and regulations; (2) information about the equipment and facilities of the organization that every employee should know; (3) a brief sketch of the history of the company, and (4), possibly an organization chart followed by a brief explanation of how the various departments function in relation to one another.

The New York office of the New Jersey Zinc Company issues an office manual which illustrates many points of good practice. This manual is published in pamphlet form and contains eight pages, including the cover. It explains briefly the facts concerning lost and found articles, cleanliness about the building, the profit sharing plan of the company, the pension plan, the library, the house organ, the cafeteria, the girls' rest room, the first aid room, the regular holidays granted, vacations, the system of periodic revision of individual salary rates, the promotion-from-within policy, the bulletin boards, personal telephone calls, methods of obtaining supplies from the stock room, fire drills and fire regulations.

It also states briefly the general office rules which apply to all employees. These include office hours, time record, absences, overtime compensation, etc.

Many of the best manuals include, beside such facts as those mentioned, a short history of the company. This is an excellent thing to include. It should be a recital of pertinent facts, rather than a glorification of achievements. It is desirable, however, to point out through the history any consistent ideals which really have characterized the growth of the organization. It is never advisable, however, to manufacture such ideals for the purpose of the history.

Of the many ways devised by personnel men for tying up the new employee to the organization, probably no method involving so little effort and expense is so effective as the orderly and interesting facts contained in a well-edited and constructive office manual.

Important Factors in Fuel Economy

IF any engineer is disposed to question the practical effect of compression ratio, gear ratio, valve timing or fuel vaporizing means, on fuel economy, we recommend that he give careful study to the paper by A. L. Nelson presented at the annual S. A. E. meeting, which we print in this issue. In fact, we think there must be something wrong with any automotive engineer who can't find food for thought in this article. Perhaps it is true that there is little that is startlingly new in the paper, but the evidence produced proves that engineers in general are either ignorant as to the improvements in economy which have been demonstrated to be possible or have failed to apply their knowledge of the subject in such manner as to produce the desired result. More power to Mr. Nelson in his effort to get engineers to take a broader view of the fuel problem! May they also apply the lessons he has taught—be they new or old—and not forget that there are also other simple means of materially improving fuel economy which are not new but which have yet to see any extensive practical application.

We predict that support of engineering research into possible methods of bettering fuel economy of modern automobiles will pay handsomely in future and believe the intelligent and progressive manufacturer should and will support it. He should give the engineer a freer hand in this matter than he has been allowed in the past.

Double Piston in Automotive Diesel Engines

IT is a noteworthy fact that in nearly all attempts abroad to adapt the Diesel engine to automotive purposes the double piston type of engine is selected. This type of construction was also used to some extent in the early years of automobile manufacture for engines working on the Otto cycle. The one make that comes to mind most readily is the Gobron-Brillie, which was manufactured in France for a great many years. But two other French pioneers, Koch and Krebs, also built engines on this principle. The object aimed at in these early engines was improved balance. With two pistons moving in opposite directions at the same speed, in the same cylinder the tendency of the reciprocating parts to cause vibration is eliminated.

Since the time when these early French motors were in vogue the double piston engine has received scant consideration from automobile engineers; it is naturally of somewhat complicated and unwieldy design, and in automobile practice balance of the reciprocating parts has been accomplished by increasing the number of cylinders to six or more. But when the Diesel cycle is to be used it is not practical to increase the number of cylinders in this way, for the reason that the smaller the cylinders the greater the difficulty of injecting fuel in the exact proportion needed. Indications now are that if the Diesel engine is ever used for automotive purposes it will be in the single cylinder form, and this being so, the use of the double piston design goes a long way in solving the balancing problem that comes up with every automotive engine.

Improved balance and reduced difficulty of fuel injection are, however, not the only advantages of the double piston design. The form of the combustion chamber during the early part of the power stroke is much more favorable than in the ordinary single piston type. This is especially important in a Diesel engine, where, on account of the high compression used, the compression space is exceedingly flat and has a large surface area relative to its volume. This means great loss to the cooling water through the cylinder jacket. The gain can easily be visualized by imagining the double-piston cylinder cut into two, the piston in each cylinder having the same stroke as the individual piston in the double piston cylinder. The flame-swept surface will then be increased by the area of the two cylinder heads. That this results in much greater cooling loss is clear.

Can We Double Mileage Per Gallon of Fuel?

IF we are to conserve our petroleum resources it is not only necessary to use the fuel in engines which are inherently efficient, but to see that the fuel furnished to the engine is mixed with the requisite proportion of air and so vaporized that complete combustion can take place in the extremely short time interval allowed. Extensive tests made by the Bureau of Mines show that **over 25 per cent of the fuel fed to the engine goes out with the exhaust in the average case.** To get better economy by preventing in some way the use of over-rich mixtures is indeed a great service problem worthy of study by the very best engineering talent, but this is only a part of the fuel problem.

By far the most important part is to use an engine which is itself inherently efficient. The constant volume or so-called Otto engine now in common use on all automotive vehicles is a highly efficient type, **providing it is designed with a sufficiently high compression pressure and is used most of the time at or near full load or in such manner that the compression is not lowered by throttling.** Unfortunately these two conditions are not complied with in average practice, but they are not impossible of realization. They have not been realized because it has proved easier to date to sacrifice them and waste fuel than to remedy them with consequent increase in economy.

This then is the problem which every engineer should study if he would make the automotive vehicle of the future truly efficient in fuel utilization. Efforts to eliminate the knock and thus make possible the use of higher compression with consequent increase in efficiency are commendable. But this alone will not suffice so long as we persist in using the throttle to limit the compression, for with other factors remaining the same, it is the compression pressure that actually obtains during the greater proportion of the time of operation that determines the efficiency.

How then can throttling be avoided in an engine which must quickly meet wide variations in load? It is possible to accomplish this in several ways. **One of these, which appears to be very promising and does not involve any very extensive change in the design of engines now used, has been tried by at lea t one prominent manufacturer in this country, and has resulted in more than doubling the mileage obtained from a given quantity of fuel.** It consists in providing two inlet valves per cylinder. Through one of these only pure air is admitted, and this supply is never throttled. In consequence the full compression pressure is maintained regardless of load. The air entering the other valve is drawn through a carbureter arranged to furnish a rich mixture containing fuel in sufficient quantity to carry the load. This mixture is diluted in the cylinder by admixture with the air which entered through the first valve, but at least a portion of it is retained in a pocket which forms a part of the clearance space. The spark plug is located in this pocket and is consequently always in contact with a readily combustible mixture at the time of ignition. At full load the quantity of fuel admitted is sufficient to unite with all the oxygen taken in through both valves, but at all lighter loads there is present an excess of oxygen which tends to promote complete combustion. The charge is, however, never too lean to burn, due perhaps to a partial stratification. Similar results have been obtained by using but one inlet valve per cylinder and carbureting only part of the air; also by the use of a properly designed fuel injection system.

Accomplishing the desired result will present difficulties which only persistent effort will overcome, but success will more than justify the means employed. **It is certainly worth while to make a real effort in the direction indicated when tests already made have shown that more than double the mileage attained with a car and engine of conventional design can be attained by the simple change outlined.**

Improvement in manifolds, vaporizing devices and carbureters should continue, **but the time has come when some more radical improvement is necessary.** We have pointed out one way in which a long step forward can be made. There are, no doubt, many other ways in which similar results are attainable. **The progressive engineer will welcome an opportunity to tackle the problem. He should receive whole-hearted support from the manufacturer.**

Buying Move Starts in New York

Many Sales Reported in After-Show Week

Entire December Business Exceeded in Some Instances—Used Cars in Demand

NEW YORK, Jan. 24—The week following the New York Show has brought an inspiring revival in automobile sales, wholesale and retail. A canvass of a majority of the distributers and factory branches shows that cars have been moving in much better volume than in November and December and in a number of places retail sales of the past week, nearly all traceable to the show, have exceeded in volume deliveries for the entire month of December.

Distributers and factory branch managers generally are agreed that dealers in the territory have a new lease of life. There were a good many show visitors from the territory, particularly from the suburban towns of New York, New Jersey and Connecticut, and the names of "foreign" prospects, promptly delivered to dealers in the outside towns, have already yielded an encouraging number of sales. Outside dealers who have been into New York or have written in since the show say that the ice has been broken and their towns are showing unmistakable signs of a steady, though gradual return of buying.

In the retail end there has been a noticeable revival in the metropolis itself. There are more people in the salesrooms than at any time since October, some have bought during the week and others are definitely in the market for March or April delivery. Sales this week have naturally been in most cases for February delivery to save the owner from obtaining a 1920 license, which expires at the end of this month.

Reports Six Sales in Week

As an instance of the "pick-up" in sales, one car in the $2500-$3000 class had six sales this week, more than in all of December, and one in the low-priced class had six a day the first four days following the show. All along the lines there have been some sales and both in personal contacts of salesmen and through mail efforts there has been an encouraging response to work on prospects listed at the show.

All along the row, in addition to actual sales and perhaps more important, there is a better feeling among dealers and salesmen. Nobody is looking for business equalling the 1920 volume but everybody is confident that a reasonable business is attainable and everybody is cheerfully working to get his share.

Truck sales have picked up slowly ever since the first of January. Business is far from normal but it is surely improving.

There are more used car inquiries than there were before the holidays and dealers have been able to take in used cars at more favorable prices than prevailed the last of last year. This is always the case as spring approaches and the hankering for a new car becomes stronger and dealers are finding encouragement in the reappearance of this condition.

The New York Show, never a big selling show, has done a lot for the trade this year and even the most conservative distributers are paying it a tribute.

Shows Curing Slump, Reeves Tells Dealers

MILWAUKEE, Jan. 22—Speaking before the Wisconsin automotive dealers at their dinner here, Alfred Reeves, general manager of the National Automobile Chamber of Commerce, announced that the New York automobile show moved the industry off dead center and sent it forward on its way toward a normal spring sales season.

Reeves said the trade could not expect to soon duplicate the extraordinary business of last spring, but with the increasing need for transportation, the motor car and truck business should be almost normal during the spring, following which sales would depend largely on the general business situation.

An industry that does more than two billion dollars wholesale and is the second largest manufacturing industry in the country naturally had to take time to slow down and will take some little time to get into its stride again, Reeves said. Some of the biggest banking houses in the country, just getting into the automobile business, declare it is now on a settled basis, declared Reeves. This includes J. P. Morgan & Co., and the Du Ponts.

Flint Raises $5,000,000 to Back Durant Motors

FLINT, MICH., Jan. 24—Citizens of Flint have subscribed an amount aggregating $5,000,000 for investment in Durant Motors, Inc., which will locate its first plant in this city. Flint regards W. C. Durant as its "favorite son" and is willing to back his new enterprise with cash. An offer has also been made to Durant of 40 acres of land.

MURRAY SUCCEEDS CURRAN

DETROIT, Jan. 24—W. J. Murray has been elected president of the Curran-Detroit Radiator Co., to succeed E. T. Curran. C. S. Reid is now vice-president; H. H. Rowe, treasurer and general manager, and H. F. Lacey, secretary. J. A. Kring and H. I. Phillips have been elected directors.

Chicago Prepared for Greatest Show

Thousands of Dealers Booked to Attend Big Convention and Exhibit

CHICAGO, Jan. 24—Chicago is ready for the twenty-first annual automobile show which will be held from Jan. 29 to Feb. 5 and which will play as important a role in the revival of business in the automobile industry as that held at New York several weeks before. Enthusiasm is being manifested outside strictly dealer circles and beyond the confines of automobile row for local merchants, theaters and restaurants have not escaped hearing of the effect of the New York show on conditions in that city.

Dealers will flock here just as they flocked to New York though perhaps in greater numbers for Chicago is more centrally located and more easily accessible to the Middle and Far West and Easterners, as a rule, rather like the idea of coming here. At any rate, reservations at the hotels in the city, large and small, indicate that nearly every inch of space available has been taken.

There will be plenty going on all the time from the afternoon the doors of the show at the Coliseum, First Regiment Armory and the New Drake Hotel, where the salon will be held, are thrown open. The truth of the matter is that business in connection with the show will start the preceding night, Jan. 28, with a dinner given at the New Drake by the Chicago Automobile Trade Association.

Graham and Kroh to Speak

Distributer members of the association have invited their Chicago sub-dealers and also their dealers from the Chicago territory together with salesmen and factory executives. George M. Graham, vice-president of the Pierce-Arrow Motor Car Co., and A. R. Kroh, who has become known in automotive circles not only through his previous active participation but through his country wide talks on the motorization of the farm, will be principal speakers. Louis A. Peil, president of the association, will be toastmaster and there will be a prominent New York banker to discuss the financial end of the industry.

From Jan. 31 to Feb. 1 the fourth annual convention of the National Automobile Dealers Association will be held at the Hotel La Salle, the third annual trade frolic to be held in connection with it.

On Feb. 1 the annual dinner and election of officers of the Old Timers Club

(Continued on page 191)

Ford and Banks Spar on Financing

Both Sides Veil Progress of Deal

Manufacturer May Offer Securities Direct to Public—Size of Loan Sought Unknown

NEW YORK, Jan. 25—Wall Street and the financial circles adjacent thereto have been greatly excited for the past few days about the financing of Henry Ford. They admit he needs to be financed and they have evolved a dozen or fifteen ways of doing it. According to Wall Street negotiations are closed every afternoon only to be opened the next morning. It is stated to-day that various banks admit that the deal is virtually completed only to have the banks deny it to-morrow. Meanwhile the person who naturally would be most interested is standing pat and saying nothing.

So much has been heard in the past week about the dire need of Ford for funds and about his frantic appeals to the banks for assistance that the impression is gaining ground that the barrage of reports and rumors has been sent up more or less as a smoke screen.

One solitary fact stands out. That is, that Ford undoubtedly will find it necessary to do some financing in the near future. His representatives do not deny that he is short of cash and that large sums must be raised to meet taxes, trade acceptances, and other obligations falling due soon.

There is very good reason to doubt, however, that Ford will play "Daniel in the Lion's Den" for the banks. He never has had any love for bankers, and bankers have reciprocated his feeling for them. It can be regarded as certain that if he negotiates a large loan it will be on his own terms rather than theirs. If he cannot make arrangements reasonably satisfactory to himself, the chances are that he will attempt to sell securities direct to the public, and it is known he believes such an offering would be successful. Some banks are inclined to agree with him. If Ford does ask the public for funds it is now considered likely that he will offer bonds rather than stock. These bonds would offer an attractive return.

Estimates Range to $100,000,000

Wall Street estimates of Ford's needs, range all the way from $25,000,000 to $100,000,000. It is not probable that even Ford himself knows what the figure will be. It is understood that his current obligations, aside from merchandise accounts and Federal taxes, are less than $25,000,000 and represent trade acceptances due in March. In addition to this a large sum will be needed to put his factory into operation again. His Federal taxes are estimated at from $30,000,000 to $40,000,000.

Ford has neither confirmed nor denied reports that he was negotiating with New York bankers, and it is probable there have been discussions in regard to a large loan. It is equally probable, and in fact practically certain, that Ford has declined to agree to the demands of the banks, which are understood to have insisted on an arrangement which would have given them practical control of the company's finances and left Ford in control only of the manufacturing end.

Seeks "Friendly" Institutions

It can be said positively that if Ford does arrange a large bank loan, it will be with institutions which are relatively friendly to him and not with those which are eager to get him into their power. One of the banks friendly to Ford, and with which he has done much business, is the Liberty National of New York, classed as a Morgan institution. Joseph A. Bower, a vice-president of the Liberty National and formerly a banker in Detroit, spent virtually all of last week in Detroit and is understood to have been offered the position of treasurer of the Ford company. He declined to accept, however. Bower refused to-day to discuss the Ford situation beyond stating that the Detroit manufacturer might not find it necessary to borrow any money at all.

The reports that Ford was in the market for funds have been made the texts of sermons on finance preached to him by financial papers. It is probable that these editorial discussions have been inspired by powerful financial groups. The substance of them has been that Ford should have stuck to the manufacture of automobiles and not purchased railroads, coal mines, iron mines and timber lands. He also has been taken severely to task for the attacks upon the Jews made by the Dearborn *Independent*, owned by him!

FORDSON TRACTOR CUT

DETROIT, Jan. 26—The price of the Fordson tractor was reduced to-day to $625, the new price to be effective at once. This is a reduction of $165.

Dr. Samuel S. Marquis, head of the sociological department of the Ford Motor Co., has offered his resignation. It has been mutually agreed, he said, that no action was to be taken on it for the present. He declined to discuss his reasons.

Wills Distribution to Start in March

Final Work on First Production Starts—Molybdenum Steel Features Construction

MARYSVILLE, MICH., Jan. 22—The first cars from the production line of C. H. Wills & Co., will be completed within a few days. The car is to be known as the Wills Sainte Claire.

While the actual price has not been announced, it is known that it will sell for approximately $3,000, or about $1 a pound. Complete technical details on the car will not be available until it is in the hands of the dealers, which is expected to be sometime in March. It incorporates, however, an eight-cylinder, 60 deg. V type engine mounted on a chassis of 121 in. wheelbase, and equipped with 32 x 4½ in. cord tires. Probably the most outstanding feature of the car is the extensive use of molybdenum steel which is employed in all parts of wear and stress. It is stated that by the use of this alloying substance it has been possible to produce steel of 185,000 lb. per sq. in. tensile strength. This has been affected by the use of chrome-nickel molybdenum alloys. The highly stressed motor parts such as the crankshaft, connecting rods, etc., are all of molybdenum steel, as well as the chassis wearing parts, even to the springs.

Engine Wills Product Throughout

The eight-cylinder engine has a bore and stroke of 3¼ by 4 in. It develops approximately 70 hp. and gives the car a speed range on high gear of from 2 to 70 miles per hr., or better. The engine is a Wills product throughout being the only overhead camshaft, eight-cylinder engine in use on this side of the water. The camshafts which are mounted above the blocks on each side of the engine are driven by spiral bevel gear shafts from the crankshaft, the drive being taken up the front end of the block by the spiral bevel gears and then to the camshaft, which extends overhead with the cams integral, driving the valves which open downward into the cylinders direct. The use of the eight-cylinder engine with a short, sturdy crankshaft and with a 60 deg. angle, permits an exceptionally fine opportunity for balance, and the result is that no period is discernible in driving the car.

The Detroit representative of AUTOMOTIVE INDUSTRIES had the privilege of driving the car over the roads around Marysville and found it to have exceptional accelerative ability throughout the entire speed range. The light weight of

Bay State Factories on Low Schedules

Return to General Operation Progresses Slowly — Wage Scales Revised Slightly

SPRINGFIELD, MASS., Jan. 24—Automotive trade conditions in Worcester and Springfield show several encouraging signs, although there is no marked change for the better.

The Norton company has announced a 10 per cent cut in salaries, effective Feb. 1. Wages have not been cut up to the present time, but working hours have been reduced considerably. Every effort is being made to hold experienced workmen, and something like 50 per cent of the normal number of workmen is still employed.

The Worcester Pressed Steel Co. is operating at 20 per cent normal. Wages have not been cut, but readjustments are being made in the case of certain classes of unskilled workmen.

The open shop movement is being vigorously supported by employers in this section and several union strikes outside of the automotive industry are now in progress as a result of wage reductions.

Gilbert & Barker in Springfield furnish an encouraging variation from the general depression in most manufacturing plants. This firm, which normally employs about 1600 workers, has laid off only a few hundred men. It is continuing manufacture at nearly 85 per cent of normal. Neither day rates nor piece rates have been cut and there is no immediate intention of such action.

The new Westinghouse Electric & Mfg. Co. plant at East Springfield, is in operation on a greatly curtailed schedule and no additional men are being hired at this time.

A slight cut in piece-work rates has been made at the Hendee Mfg. Co., makers of the Indian motorcycle. Operations are continuing at about 40 per cent of normal both on the heavy machines and on the scott model. This is a union shop, but no serious difficulties were experienced when it was found necessary to make wage reductions in view of present conditions.

Throughout this section a general opinion prevails that business has started very slowly on the up-grade, and that a gradual return to normal will be experienced from now on. There is no indication, however, of any sudden increase in manufacturing activity.

Motorcycle Schedule Set at 55,000 for 1921

SPRINGFIELD, MASS., Jan. 24—Motorcycle production for 1921 will probably drop slightly below the 1920 level, according to the best estimate now available. The Hendee Mfg. Co. schedule at present calls for some 15,000 to 18,000 machines this year, while the Harley-Davidson schedule has been reduced to about 18,000. During 1920 both of these concerns made over 20,000 machines, and their plans for the coming year give an excellent indication of the trend of production, since these two, together with the Excelsior organization, produce the vast majority of motorcycles now made in this country.

In 1920 about 70,000 motorcycles were prduced in the United States, while present indications point to a production of about 55,000 for the present year. Brightening of general business, conditions, of course, would serve to raise this estimate again.

Goodrich Creates Fund for Contingent Losses

NEW YORK, Jan. 24—Directors of the B. F. Goodrich Co. have voted to set aside out of the surplus a reserve of $10,000,000 to provide for all possible contingent losses on raw material commitments for future delivery. A dividend of 3½ per cent has been declared on the preferred stock, half of which is payable April 1 and the other half July 1. Action in regard to the May dividend on common stock will be taken at a meeting in April. A statement by the directors says:

"Audit of the accounts for the calendar year 1920 has not been completed, but the general result indicates that earnings for the year will be very largely consumed in writing down the inventory of raw materials on hand at a fair market value. Net sales for the year amounted to approximately $150,000,000."

ReVere Motors Solvent Assets Triple Debts

INDIANAPOLIS, Jan. 22—A finding of solvency in the bankruptcy proceedings instituted against the ReVere Motor Car Corp., of Logansport, three weeks ago, has been made in Federal Court by Harry C. Sheridan of Frankfort, special master. The decision has been expected ever since the hearing last week, when Sheridan indicated he was convinced of the solvency of the concern. The finding points out that expert accountants had testified that the assets of the company on Nov. 30, 1920, were $1,157,328.59 and liabilities only $354,659.90, and that no attempt to question or contradict the figures had been made. The proceedings were brought by three Chicago concerns.

DUPLEX ADDS TWO DIRECTORS

LANSING, MICH., Jan. 21—The Duplex Truck Co. has increased the number of its directors and the new members elected are Bert S. Gier and Charles W. Nichols. President H. M. Lee stated that the sales department has received more inquiries and orders since Jan. 1 than during the entire period of the slump in the automobile business.

AIR FIELD APPROPRIATION ASKED

HARTFORD, CONN., Jan. 24—The Hartford Municipal Aviation Commission has asked the city for an appropriation of $12,500 to provide a landing field for aviators who wish to stop in the city.

Garages Continue High Wage Scales

Concerted Reductions Thought Delayed by Unusual Amount of Repair Work

NEW YORK, Jan. 24—Though there has been no concerted action on the part of garage men to reduce wages of mechanics to a rate approximately that existent before the war, or any specified rate, there is a widespread movement throughout the industry to cut down on wages boosted to unnatural scales by the exigencies of the war-time situation.

New rates of compensation are based entirely upon the conditions existing in the individual communities in which they are applied. In many cases only scattered shop owners in cities like Boston, Philadelphia, New York and others, which number hundreds of garages, have cut wages, but they have suffered no dearth of mechanics, and their work apparently has not been less efficient.

Detroit is perhaps the only city in which concerted action has been taken by an association of owners, the Detroit Automobile Dealers Association having promulgated an entirely new scale of wages in which all concur, and the mechanics have seen the advisability of accepting. Where higher rates have been sought by mechanics in the past few months, owners have acted in concert in opposing them and have been successful. Unions were principally responsible for this activity, notably in New York, Kansas City, and several cities in the West.

Cities which report no concerted wage reduction activity are Boston, Philadelphia, New Orleans, Cincinnati, Sacramento, Cal., New London, Conn., Rock Island, Ill., and Cedar Rapids, Iowa. In all of these there have been individual instances of reductions and general cuts are believed to be, as in Philadelphia, only a matter of time.

A notable reason, perhaps, for the failure of a concerted reduction move to materialize to this time is the unusual amount of repair work being offered to garages, ascribed to open weather conditions, and also to the belief that many owners will make their old cars carry them over for another season or two.

FOUNDRY DIRECTORS RE-ELECTED

BELDING, MICH., Jan. 22—The Belding Foundry Co. has re-elected the present board of directors which consists of Henry J. Hartman of Grand Rapids, J. C. Jenkins of Big Rapids, A. B. Johnson, Albin Johnson and William F. Sandell of Belding. It was announced to the stockholders that the business during the past year had been very satisfactory and that the outlook for this year is good. There is no doubt that with the gradual improvement of general conditions throughout the country that the company will get more business and perhaps make this its biggest year, officials said.

Canada Plans Split on Excise Refund

Manufacturers to Share Dealer Burden on Unsold Cars—General Business Better

OTTAWA, ONT., Jan. 22—The buyers' strike, so far as the Canadian motor trade is concerned, is rapidly breaking down. Many dealers and distributers report more actual sales during the past three weeks than during the preceding three or four months. The feeling is general that the corner has been turned and pessimism has been deposed by optimism.

A week ago Friday, a joint committee of Canadian dealers and manufacturers conferred at Ottawa with Sir Henry Drayton, Minister of Finance, in support of the request made by the deputation of dealers from all over the Dominion, which had urged him to use his good offices to induce the Government to rebate to the dealers the excise tax (15 per cent ad valorem on cars retailing under $3000 and 20 per cent on cars retailing at $3000 and over paid on unsold cars in stock at the time of the repeal of the excise tax.

The Minister made clear his sympathy for the Trade but pointed out difficulties with which he was faced. No precedent for the requested refund would make it necessary to have an Act of Parliament passed during the forthcoming session of the Legislature to sanction it. Lack of funds would make the reimposition of the tax in part necessary to raise the moneys wherewith to make the refund. Other trades and industries similarly circumstanced would also demand refunds and so forth.

The manufacturers' representatives then tentatively agreed that provided the Minister of Finance would agree not to impose further taxes on motor vehicles they would rebate the dealers and set prices that over a period of a year would extinguish the refunds. Owing to the sales resistance factor, it was later agreed at a meeting of the manufacturers in Toronto that an increase in car prices would be very ill advised at this time, particularly as the public, in all probability, would learn of the reason for the increase and would therefore, to a considerable extent, continue the sales siege until the absorption of the loss in question permitted price reductions. A continuance of sales resistance would be extremely harmful, it was agreed.

Would Maintain Present Prices

The proposal was then made that the manufacturers meet the dealers half-way by absorbing fifty per cent of the loss with which they (the dealers) were faced, without increasing the price on their cars. It was hoped originally that all the Canadian manufacturers would concertedly adopt this expedient. Possibly all will but certainly not concertedly for to-day the General Motors of Canada, Ltd., McLaughlin, Chevrolet and Oldsmobile, and the Willys-Overland, Ltd., have advised their dealers that they have decided on the 50-50 plan.

It is believed the other car manufacturers will soon follow suit or possibly announce independent plans. The Ford Co. of Canada, Ltd., in a telegram to the Toronto Automobile Trade Association, stated that action, if any, would be deferred till the end of the month, at which time the Ford dealers' convention will be held.

Former Navy Planes Find Canadian Buyers

NEW YORK, Jan. 24—The Aeromarine Engineering & Sales Co. which recently acquired surplus aircraft and engines from the Navy Department, announces that the Canadian Government recently purchased ten Navy flying boats which are to be utilized in forest patrol and in connection with the Canadian northwest mounted police. It also announces that negotiations are pending which will result in the establishment by next July of an aerial transportation and freight line between Edmonton and Great Slave Lake and Fort Norman in the McKenzie River basin.

This is the region in which there has recently been such activity in connection with the discovery of oil and the plan is to transport prospectors over the 800 or 900 mile route by air. The aerial transsportation line which is to utilize the Aeromarine navy flying boats, following the course of the McKenzie River and nearby lakes, will carry passengers over this route in twenty-four hours, whereas by pack and canoe, the time required is from six weeks to two months.

Under its arrangement with the Navy, the Aeromarine company will be able to sell flying boats on the installment plan instead of for spot cash. The purpose of this plan is to encourage civilian flying and thereby facilitate the training of an aeronautical reserve. The price of these boats has been fixed at $6,160.

SEEK $500,000 FOR IMMEL

COLUMBUS, Jan. 22—At a meeting of the stockholders of the Immel Co., manufacturers of automobile bodies, which is in the hands of Robert H. Schryver, receiver, a committee was named to solicit funds to raise the receivership. H. S. Gilmore was named chairman of the committee. It is planned to raise $500,000 of which $400,000 will be necessary to raise the receivership leaving $100,000 for working capital. In the meantime work at the plant is practically ended although there are about 40 closed bodies to be completed before the plant is entirely closed down.

SPARTON TANKS ENJOINED

NEW YORK, Jan. 24—The United States Court of Appeals his upheld the decision that the manufacture of Sparton vacuum tanks by the Sparks-Withington Co. is an infringement of the Stewart-Warner patents and has enjoined the further manufacture of Sparton vacuum tanks.

Protests Unheeded, Truck Sales Go On

Coast Dealers Aroused Over Failure to Prevent Dumping of War Vehicles

LOS ANGELES, Jan. 22—Motor truck dealers here are feeling keenly the effect on business of the arrival and sale of seventy-five trucks brought from Europe. Protest has been made against this sort of competition to the National Automobile Chamber of Commerce, National Automobile Dealers Association, congressional representatives and others but there has been no suggestion of relief. "It's too bad" and "It ought not to be allowed," are expressions received but further than that nothing has developed at this time.

A meeting of the truck dealers of the city has been called for Thursday night at which time some plan of action may be decided upon. It is understood that the seventy-five trucks already received will be followed by more and that is the thorn that is sticking the hardest, as representatives of all but one truck line are wondering when the end will be. The one exception is the Transport truck dealer who is acting as sales agent for the imported trucks. This dealer has issued the advertising over his signature and is advocating the sale of the trucks at "about one-half the list price."

Speaking for the other truck dealers as well as himself, one dealer said to-day: "It would seem there is some way to control a proposition of this kind but the way is undiscovered. Where is our so-called protective tariff? These trucks originally were American-made but they are not American property now and are being sold in direct competition with our trucks that have to pay no end of special taxes? Handled as they are, it is not even necessary that the owner have a dealer's license. We understand additional shipments now are en route.

"There are enough American-made trucks now in Europe to become a serious menace to the entire market in this country if all are brought over here. What sense was there in American manufacturers insisting that the war trucks and automobiles originally shipped to Europe be left there and sold away below their real value, if now they are to be brought back here as privately owned and be put on the market? The truck business to-day is bad enough without having such a situation to deal with."

TO BUILD PETROLEUM ENGINE

CHICAGO, Jan. 21—The Petroleum Motors Corp., organized about eighteen months ago to develop an opposed piston type, heavy duty truck and tractor engine to operate on low grade fuels, has completed its experimental work and has reorganized for $1,250,000 par value $10 per share to go into the manufacturing of these engines, and will soon start production on a small scale.

Wilson Advocates Air Mail Operation

President Concurs in Report of National Advisory Committee —Bill Before Senate

WASHINGTON, Jan. 24—Concurrence of President Wilson was appended to the report of the National Advisory Committee for Aeronautics, recommending continuance of the air mail service, which was transmitted to Congress today. The report declared that the air mail service was a necessary means for the development of the civil aircraft activities of the nation.

The practicability of heavier-than-air planes for civil as well as military uses has been demonstrated by the air mail service, the report asserted, and adds that though the value might not be apparent in terms of dollars and cents it would be easily seen should the nation be called upon again to mobilize its air forces.

The report was signed by Joseph S. Ames, chairman of the executive committee of the National Advisory Committee, which is composed of representatives of the Army and Navy and several prominent civilians.

The Post Office Appropriation bill, from which the House cut $1,250,000 intended for the air mail service, is now before the Senate Post Office Committee. Unless the Senate makes provision for the service, no funds will be available for it after June 30.

Madden to Push Probe of Larsen Purchases

WASHINGTON, Jan. 24—Congressman Madden of Illinois, announced today that he intended to press for action on his resolution introduced in Congress last week requiring the Post Office, War and Navy Departments to report details regarding the purchase of German airplanes. It is claimed that the purchases were unauthorized and a violation of treaty obligations. The destruction of three metal planes and the loss of life is said to have inspired the inquiry.

According to the Congressman, the planes used by the Post Office Department were purchased through an agency controlled by John Larsen. These eight machines cost the Government $12,500 each, while the War Department purchased three at a cost of $100,000. The War Department planes had additional equipment. The Navy Department paid out the same amount for three monoplanes.

Zeppelin Branch Here Declared Possibility

NEW YORK, Jan. 24—Since the visit to America last summer of representatives of the Zeppelin interests, there have appeared from time to time in the public press many contradictory reports as to the future plans of this company. Apropos of this an item which appeared in the German "Flug-Welt" of Nov. 24, 1920, will be of interest.

According to this report, certain commercial steps were discussed and negotiations initiated with regard to the delivery of a ship. However, no contract was made and nothing conclusive resulted from these preliminaries. In point of fact, according to "Flug-Welt," the Zeppelin plant is still inoperative by reason of treaty regulations, and the use of the company's commercial ships has also been forbidden awaiting certain discussions of the Air Commission. Meanwhile, of course, the company is cut off from international competition.

"The transfer of the Zeppelin plant to the United States is clearly impossible," says "Flug-Welt," "it is, however, not impossible that a branch may be started in that country in the future."

Harvester Price Probe Urged Upon Congress

WASHINGTON, Jan. 24—A resolution asking for investigation of complaints that the International Harvester Co. has announced its intention of increasing the price of some of its farm machinery products was introduced in the House to-day by Representative Jones, Democrat, of Texas. The House Interstate Commerce Committee is directed by the resolution to make an inquiry and if prices have been raised to find out why.

Company Welcomes Inquiry

CHICAGO, Jan. 24—The following statement was made by officials of the International Harvester Co.:

"While we have no detailed information about the resolution, we will welcome any inquiry along the lines, being satisfied that the only result will be to convince the public of the fairness of our prices.

"Our prices are now and always have been based solely on the cost of production. Our current prices are practically the same as for the last ten months. There have been some slight increases on some machines and reductions on others, with the result that, considering our line as a whole, the price level for 1921 is substantially the same as for 1920."

WOULD CHANGE TRUCK DESIGN

WASHINGTON, Jan. 24—Suggestions have been advanced to automotive engineers by Earl B. Smith, senior assistant testing engineer, Bureau of Public Roads, for changes in the design of motor trucks which would distribute the load more nearly equally between the front and rear axles so that the load on the rear wheels would be lessened. This recommendation is made in an effort to reduce the cost of highway repairs.

MAXWELL-CHALMERS ADDS MEN

DETROIT, Jan. 24—Maxwell-Chalmers Corp. has added 450 workers to the operating staff during the past week and will make further additions this week.

Depression Defers Standard Parts Plan

Committee Votes to Continue Receivership When Stock Subscription Falls Short

CLEVELAND, Jan. 24—The receivership of the Standard Parts Co. will be continued for the present owing to the failure of stockholders to raise sufficient funds through the subscription of new stock, to place the company back upon firm financial footing. This decision was made unanimously at a meeting of the reorganization committee Friday at the Cleveland Trust Co.

Failure of the re-establishment of the company to go through as planned is ascribed to the financial depression which made it impossible for many of the stockholders to take their portions of the new stock.

The report to the creditors of the reorganization committee, consisting of F. H. Goff, chairman; George A. Coulton, John Sherwin, E. E. Walker, H. C. Robinson, Cyrus H. Eaton, Leon F. Payne, H. W. Chapin and H. L. Thompson, follows:

"On Oct. 26 your committee advised you that the committees representing the preferred and common stockholders of the Standard Parts Co. had agreed upon a plan whereby reorganization of the company would be effected through the sale of new issues of preferred stock in the amount of approximately $6,000,000, arrangements to be made with certain banks for lines of credit of $4,000,000.

"At that time your committee believed that stockholders would be able to take new issues of preferred stock.

"Owing to the financial depression and the difficulty of securing money, many of the stockholders were unable to take the pro rata share of stock which it was contemplated they should take of the new issues, and the reorganization committee has been unable to secure sufficient subscriptions or to complete the plan.

"For the above reasons it is the opinion of your committee that the company should continue under the receivership under closer co-operation with your committee.

"From time to time this committee will report the progress made by the receivership, and if times become more propitious and a new plan for reorganization is submitted by the reorganization committee, this committee will consider the same and advise you concerning it."

STAR TIRE ALLEGED BANKRUPT

AKRON, Jan. 22—A petition in involuntary bankruptcy has been filed against the Star Tire & Battery Co., Steubenville, O., on the petition of three creditors whose claims aggregate $4,161.90. The creditors are the Goodyear Tire & Rubber Co., Kokomo Rubber Co., and the Gulf Refining Co.

Chicago Prepared for Greatest Show

National Tire Dealers' Association to Be Organized—N. A. C. C. and S. A. E. to Meet

(*Continued from page* 186)

will be held in the Florentine room of the Congress Hotel. This organization, composed exclusively of veterans in the automobile industry was initiated at the New York show a year ago by one of the old timers. The organization will be perfected at the meeting next month. The nominating committee has selected for president, Albert Champion, president of the Champion Ignition Co. of Flint.

Show week, Jan. 31, to be precise, will see the inauguration of a national tire dealers and vulcanizers association which will bring together all the individual tire dealers organizations throughout the country. The meeting will be held in the Morrison Hotel under the auspices of the Chicago Tire Dealers Association, and will continue over Feb. 1 and 2 and Feb. 3, if necessary.

The directors of the National Automobile Chamber of Commerce will hold a meeting on Feb. 2 and on the same evening the annual dinner of the Society of Automotive Engineers will be held at the Morrison.

On Feb. 1, at the Congress, the Motor Truck Manufacturers Association will hold their annual meeting and on the following day at the Morrison will be held a meeting and dinner of the Chicago Truck and Tractor Association.

For three days, Feb. 2 to 4, the Automotive Electric Service Association will meet at the La Salle.

Cleveland Exhibit Gets Flying Start

CLEVELAND, Jan. 23—Saturday's attendance in spite of rain was 20 per cent above the opening last year and a Sunday crowd which exceeded all Sunday records, gave the Cleveland Automobile Show a flying start. The management and the dealers were frankly surprised at the outpouring with the admission raised from 50 to 75 cents, and accepted it as an indication that volume buying is about to return.

The show opened in a heavy downpour which only partly cleared away in the evening, but people came just the same. Actual paid admissions at the gate were 2076, as compared with 1954 last year, and the grand total of attendance, including complimentary and reduced price tickets sold to dealers for distribution was 6000, as against 5000 in 1920. Sunday was clear and cold, and the crowds thronged the aisles until 11 p. m., numbering about 50 per cent above that of Sunday last year.

There were a number of sales Saturday. Then the big rally this noon, attended by dealers from all over Ohio, put additional inspiration into the trade to make this one of the best shows of this city of successful dealer expositions.

All of the Cleveland manufacturers are represented by complete exhibits of their products. Factory representatives are paying close attention to buying indications with a view to forming a production policy for the first part of the year. There are few cars stocked at the factories and manufacturers are desirous of meeting demands with immediate deliveries.

Exhibit Seven Vehicles at Electrical Show

NEW YORK, Jan. 24—Manufacturers of five electric commercial trucks and two electric passenger cars will exhibit at the electric automobile show which opens Saturday at the showroom of the New York Edison Co., this city. In addition there will be exhibits by manufacturers of batteries, charging apparatus and accessories.

Trucks assigned space are Commercial, Lansden, Oneida, Walker and Ward. The passenger cars are Berg and Rauch & Lang. Battery makers exhibiting are Edison, Electric, General Lead and Philadelphia. Apparatus and accessories, Anderson Mfg. Co., Auto Electric Devices Corp., Allen Bradley Co., Cutler-Hammer Mfg. Co., General Electric Co. and Westinghouse Electric & Mfg. Co.

There will be no admission charge to the show and the space to exhibitors has been granted without charge. In the week starting Feb. 7 there will be an exhibit of industrial trucks.

Automotive Stocks Show Market Gains

CLEVELAND, Jan. 25—Transactions on the Cleveland Stock Exchange indicate that the automobile industry in this district is picking up. Shares of practically all automobile manufacturing establishments in this city have sold up from one to five points in the last week. Grant Motor common has come up from 1¾ to 3¾ points. Peerless has risen three points; Standard Parts three points, and other stocks have shown strength.

Recent strength in automobile shares was brought about by the belief that the automobile shows in New York, Chicago, Cleveland and in other cities would show the trend of automobile demands. No one expects a mad scramble of buying, but there is a strong belief the next month or two will bring about steadily increasing orders. Foreign demand for cars also is expected to be above normal.

PHELPS IN RECEIVERSHIP

COLUMBUS, Jan. 24—Upon the application of Louis N. Reif, a holder of a note for $3000 against the company, Judge Duncan has named J. H. Weisenback and Thomas W. Pickard receivers for the Phelps Mfg. Co., a manufacturer of wire wheels for automobiles. The company had a capacity of about 100 sets of wire wheels daily. Pickard reports that operations are being continued under orders of the court.

Dealer Sues Davis for Contract Breach

Damages of $4,357.88 Asked As Extra Commission Due On Sales for Year

INDIANAPOLIS, Jan. 22—Suit for $9,357.88 for alleged breach of contract was filed against the George W. Davis Motor Car Co. of Richmond by Spencer G. Kuhn of Cincinnati, in Federal Court, here.

The complaint charges that Kuhn and Amos E. Chevraux, comprising the A. & K. Automobile Co. of Cincinnati, held a contract for the exclusive sale of the Davis car in Hamilton County. By the contract they were to be allowed a discount of 27½ per cent from the list price of the cars, with an additional allowance of 2½ per cent in the event fifty cars were purchased during the life of the contract.

On June 23, 1920, one week before the expiration of the contract, the A. & K. Co. is said to have ordered seven Davis cars, which would have completed the quota of fifty; but the Davis company refused to ship the automobiles, and to pay the extra commission of 2½ per cent, amounting to $4,334.75 on the forty-three cars already purchased.

It is also charged that the Davis company violated the contract by increasing prices without the notice required and by shipping defective cars.

Court Issues Order to Sell Van Briggle

INDIANAPOLIS, Jan. 22—Upon the report of Mahlon Bash, representing the reorganized directors of the Van Briggle Motor Device Co. of this city that the directors were unable to raise sufficient funds to continue the business in operation, Judge Harry O. Chamberlain of the Marion Circuit Court has issued an order directing that the plant and all assets of the company be sold for the benefit of creditors.

The report showed that the reorganization of the company on a sound basis was impossible and that the directors could see no reason for attempting to carry on the business further.

William R. Hirst, receiver of the company, was ordered to remove his office from the plant to cheaper quarters in the downtown district. Creditors of the company will be given six weeks in which to file claims.

Several weeks ago the receiver filed suit against L. H. Van Briggle, president of the company, alleging that he had obtained more than $240,000 from the company through fraudulent means.

DUESENBERG SUES ON WAR WORK

NEW YORK, Jan. 24—The Duesenberg Motors Corp., one of the Willys subsidiaries, has sued the Government to recover $1,201,851 on contracts for the manufacture of Liberty motors.

British Companies on Firmer Standing

Balance Sheets of Older Concerns Indicate General Weathering of Depression Period

LONDON, Jan. 5 (*Special Correspondence*)—It is both reassuring and significant amid the undeniably adverse state of the trade that the older British companies look like weathering the financial storm. Now that the balance sheets of some of these businesses are coming through, the reports show both a profit earned in a notably disappointing and vexatious year—vexatious because of the hold up of output at the beginning caused by labor troubles, and the sudden cessation of demand and increasing financial tightness which occurred toward the close.

The Rovers Co.'s profit is a good average, so, also, is the first report of the S. T. D. group—the fusion of the Sunbeam, Darracq and Talbot companies—which group also owns the chief motor trade leaf-spring business, that of Jones, Woodhead & Co. of Leeds, and also the truck and other products business of the W. & G. du Cros Co. The net profits of the S. T. D. group are given as £325,000 (nom. $1,625,000 pre-war rate) and the cash assets as £560,000 (nom. $2,800,000 pre-war rate), this item representing 15 per cent of the total assets.

Both the Sunbeam and Darracq outputs were approaching normal, but the Talbot was much below normal, and a new light "four" Talbot model, prepared for the 1920 season, is still in abeyance, though the first samples had been well tested before the 1919 Olympia show. This model has not been dealt with in the press, and here it need only be noted that it seems to be just the sort of chassis for a mass production job likely to sell well here. Probably the fact that the times are inauspicious for such a model explains its being held back. On a 10,000 output yearly the selling value—in normal times, but allowing a continuance of the present wage rates—should be £200 ($1,000) or with a standard body and full equipment at not exceeding £300 ($1,500).

Government Work Still on Hand

Napier and Rolls-Royce have done well financially, but as both had Government work on hand it would be difficult to appraise the worth of their general trading.

The Humber company, one of the oldest and most popular British companies, has declared a net profit on the year of £104,218 (nom. $521,090 pre-war rate), though the net balance, including the sum brought forward from 1919, is a net profit of £215,793 (nom. $1,078,965 pre-war rate). This company, besides labor troubles, had the further set-back of a big fire which burnt the larger portion of the body-shop, and as much of the hold-up of motor output in general was due to the shortage of bodies, it can be understood what this loss meant to the company.

The Humber company, like Sunbeam, Rover and Talbot, and one or two others, resumed manufacture *of their pre-war models, making detail improvements where economically based and justifiable, so that the lesson of their common prosperity is not far to seek.* As regards the Humber result, it should be noted that it includes profits from the company's cycle and motorcycle departments, in both of which it holds a great name and has the advantage of a splendid tradition.

As regards some other established British motor companies, their returns can only be conjectured, and in some cases the accounts are involved with Government orders.

It should also be noted that the present price of the scrip and stocks of some, if not most, British motor companies does not reflect the accepted asset value of the businesses, as can be easily seen by noting the yield as from recent dividends.

Metropolitan Securities Forms Canadian Branch

MONTREAL, Jan. 21—Canada-Metropolitan Securities Corp. has been organized with a capital stock of $1,250,000, divided into $500,000 of 8 per cent cumulative shares and $750,000 common shares, both of the par value of $10. The special function of the new organization is automobile financing, and it is a link in the chain of the "Metropolitan plan" in the United States. The Confederation Investment Corp., Ltd., is the fiscal agent of the new company. The officers and directors are William F. O'Connor, Ottawa, president; Alexander Michaud, Montreal, vice-president; Major Daniel Owen, Ottawa, secretary-treasurer; R. S. Weir, K. C. Frank, W. Knowlton, T. H. L. Saunderson, Montreal, and H. W. Ritter, Cleveland, directors. The Ritter Commercial Trust of Cleveland, guarantees the preferred dividend for ten years and undertakes direction of the management for the same period, and at the end of the period offer to repurchase any preferred stock which may be offered at par.

FULTON BUYS WELLAND PLANT

WELLAND, ONT., Jan. 22—Instead of St. Catherines as was at first planned, the location of Fulton Motors, Ltd., is Welland and the company will establish a plant here having recently closed an option for the purchase of the land, building and plant of the Canadian Automatic Transportation Co.

AUSTRALIA BARS ALL "BOSCH"

NEW YORK, Jan. 21—Mark Sheldon commissioner of the commonwealth of Australia, announces that a proclamation gazetted Dec. 30 prohibits the importation into Australia of all goods bearing the word "Bosch."

England Shows Gain in Tire Shipments

Imports of Cars, Chassis and Parts to November 30 Reach $110,092,775

LONDON, Jan. 5 (*Special Correspondence*)—Britain imported in November 1350 cars and 561 chassis, as against 704 and 238 respectively in November, 1919. The total number of imported cars and chassis for the eleven months of the year was 31,916 *cars and* 11,838 *chassis, as compared with* 3064 *and* 1379 *respectively for the eleven months of* 1919.

The value of the month's imported chassis parts was $3,204,595, against $462,935 in November, 1919. For the eleven months the combined value was $38,603,520, as compared with $13,377,845 for the like period in 1919. The combined value for the eleven months of the cars, chassis and parts imports was *the enormous sum of* $110,092,775, *as against* $19,912,780 *for the like period and combined totals in* 1919.

November's import value of tires was $2,111,405, as compared with $1,108,935 for November, 1919; the eleven months' totals being respectively, in 1920, $25,789,925, and in 1919, $9,063,135.

These figures, though taken at the pre-war rates of exchange—a fact, of course, responsible for a difference in the gross value calculated at the present unfavorable state of the British pound sterling—very sufficiently show the enormous volume and value of the motor and tire import trade with Britain. Of this combined trade the United States has about eight-tenths, if not more, and the total is increasing.

British exports of cars in November were 814 and of chassis 296, as compared with 198 and 84 respectively in November, 1919. *The eleven months totals were* 4720 *cars and* 2835 *chassis, as compared with* 1296 *and* 569 *respectively for the like period in* 1919. The month's value of exported parts was $920,735, as compared with $644,850 in November, 1919. The eleven months' total value of parts exported was $9,029,230, as against $4,861,095 for 1919. For the eleven months the combined total values of exported cars, chassis and parts were $37,177,560, as compared with $11,548,745 for the like period of 1919.

$400,000 Gain Over November, '19

The value of the British tire exports in November was $2,409,680, as compared with $2,083,420 in November, 1919, the respective eleven months' totals being $30,415,610 in 1920, and $19,307,990 in 1919.

Britains most notable export advance, it will be seen, is in tires, the value of which for the eleven months is as 30 to 19, whilst the increased value of exported vehicle chassis and parts is as 37 to 11.3.

War Truck Surplus Requested for Roads

Congress Gets Bill Endorsed by National Association of State Highway Officials

WASHINGTON, Jan. 25—Congressman Frank Reavis of Nebraska has drafted a bill which, if passed, would force the War Department to turn over to the Bureau of Public Roads all surplus motor trucks, tractors, and mobile shop units. The proposed legislation has the support of the National Association of State Highway Officials who feared that the proposal of Congressman Anthony of Kansas to sell on the open market thousands of army trucks and other automotive equipment would be carried out.

Figures have been placed on file with the Chairman of the Select Investigating Committee of the House, purporting to show that $108,000,000 worth of tractors, trucks and automotive equipment is in possession of the War Department. A large part of this equipment, it is claimed, is surplus and should be transferred to the Bureau of Public Roads where it is urgently needed. Congressman Reavis is advised that there are many tractors and trucks at camps along the Mexican border which are serviceable but not in use.

According to the Select Investigating Committee of the House, the War Department has informed the Bureau of Public Roads that this equipment is not available for their use. It is asserted that the War Department further claimed that manufacturers had protective clauses in contracts which prevented the transfer for other than war purposes.

The Reavis measure would require the States taking this surplus material to pay 20 per cent of the original contract price. With allowances for mileage and other items the cost would be comparatively low. The highway officials intend to push this bill at this session though it is doubtful whether they will obtain any action.

ARMLEDER SUED FOR ROYALTY

CINCINNATI, Jan. 25—Charles Flederman, of Cincinnati, is suing in Common Pleas Court for a judgment of $14,000 against the Otto Armleder Co., motor truck manufacturer. Flederman says that in 1913 he contracted with the company for its use of an automobile patent issued to him and that he was to receive $7 for each car manufactured during the life of the patent, as a royalty. He says the company discontinued the royalty when he left its employ in 1915, and that it has used 2000 of the appliances since that time, for which he demands a judgment of $14,000. The company denies all charges.

TO REVIVE BRIARCLIFF RACE

NEW YORK, Jan. 26—The Briarcliff Race will be revived this year and while no actual date has been set, it is understood that the event will take place in May. The race is under the sanction of the Motor Club which has been absorbed by the Automobile Dealers Association and E. S. Partridge has been appointed Chairman of the Race Committee. The race will be open to stock cars only and it is expected that this revival of a classic will stir up a good deal of interest as racing has practically come to a standstill in the East since the abandonment of Sheepshead Bay Speedway.

Committee Endorses $100,000,000 for Roads

WASHINGTON, Jan. 24—A bill authorizing the appropriation of $100,000,000 for Federal aid in the construction of post roads and other highways was reported out to-day by the House Committee on Good Roads. It further provides for an additional sum of $3,000,000 for national forest roads and trails.

The proposed legislation would allow reduction in the ratio of States where the percentage of total public land area exceeds 10 per cent of the total area of all the lands in the State. This proviso is especially used in Western States.

Would Build D. A. R. Highway

WASHINGTON, Jan. 25—Congressman Zihlman of Maryland introduced a bill to-day providing for a national ocean-to-ocean highway over the pioneer trails to be known as the Daughters of the American Revolution Old Trails Act. It provides that the Government should pay half the cost of constructing and repairing the roads and that no tolls can be levied.

Texas Car Association Is Alleged Bankrupt

FORT WORTH, TEX., Jan. 26—Involuntary petitions in bankruptcy were filed here to-day against the Texas Motor Car Association by Reed & Glasser, consulting engineers of Indianapolis; Maremount Mfg. Co., and Cluley Automobile Supply Co. of Chicago, alleging an indebtedness of $4,251.06.

The petition says the Motor Car Association, which went into the hands of receivers last October, committed an act of bankruptcy in making such application.

Willys-Overland Cuts Surplus Cars to 7000

TOLEDO, Jan. 24—Surplus car stocks of the Willys-Overland company have been reduced from 12,000 to 7000 in the past six weeks, factory officials declare. It is expected that the remaining 7000 cars will be practically cleared out by Feb. 1.

President John N. Willys looks to a substantial buying movement about March 1. With this realized and the factory operating on a near normal scale, the present inventories of raw material will be worked off in three or four months, it is declared.

Goodyear Financing Nears Final Stage

Negotiators Report Satisfactory Progress Toward Working Plan —Seiberling Not Resigned

NEW YORK, Jan. 27—Negotiations for the reorganization and refinancing of the Goodyear Tire & Rubber Co. are continuing without interruption, but no official statement is obtainable concerning them except that "satisfactory progress" is being made. Something definite may be evolved by the last of this week. Bankers interested assert that a receivership now is improbable. It seems likely a plan will be worked out for mortgage bonds to take care of the secured creditors, which means the banks.

Merchandise creditors are not satisfied with the proposition made to them which calls for a certain amount of their claims in cash and the remainder in bonds or stock. They want cash and notes, on the theory that notes can be discounted. The merchandise claims amount to approximately $70,000,000. It is understood, however, that the various interests involved are getting closer together and that an ultimate agreement is considerably more likely than it was a week ago.

F. A. Seiberling, president of the company, has been in New York for several days, sitting in at the conferences, and he emphatically denies that he has resigned or contemplates doing so. He insists that the story of his retirement, either forced or voluntary, has been inspired by a banking house which is disgruntled because he would not meet its terms, which were tantamount to giving it complete control of the company. It is probable, however, that if the refinancing plan goes through, a representative of the bankers will be placed in charge of the company's finances.

May Limit Fund to $25,000,000

Plans which the bankers are working on are said to contemplate the raising of not more than $25,000,000 new money, and possibly not more than $20,000,000. in place of the $30,000,000 previously mentioned. The distribution of this fund has not been settled upon, but it was said yesterday that it was not likely any of it would go to merchandise creditors.

The latter are being grouped into two classes. Those who have claims against the Goodyear Tire and Rubber Company for goods delivered, and those whose claims rest on contracts. It was understood that the former would be asked to accept new securities for their claims, and that the latter would be able to liquidate the goods they have on hand for delivery and receive new securities for whatever readjustment is necessary. These securities. it was hoped, would be available for collateral purposes, so that creditors may be able to borrow on them.

Wills Distribution to Start in March

Five Body Models in First of Line—Production for Year Estimated at 6500

(*Continued from page* 187)
the car which, with body and all accessories, barely exceeds 3000 lb., coupled with the high torque engine, gives a very creditable performance.

The car is being made at present in five body models, these being the five passenger touring, roadster, coupé, sedan and town car. The touring and roadster models will be put through first, the roadster being ivory with Sainte Claire blue fenders. The color is named after the blue of the fresh water lakes, which is also incorporated in the symbolic nameplate or trade mark on the car. This is a wild northern goose winging its way over the pine clad shores of the lake region. The touring car is dark blue throughout, the fenders and running gear having the same color as the body. All of the cars are equipped with disk wheels of a special design as standard equipment and no options are being offered on this. The wheels are special design with a convex rather than a concave disk. The wheels and bodies are at the present being made by the Budd company and the trimming is done at the Marysville factory.

In lines, the car presents a rather low appearance, the front view being rather square due to the rectangular radiator, with a very slightly raised center. Mechanically the car presents a number of very unusual features. For instance, the three-bladed, cast aluminum fan is designed to cut-out at high speed so as not to absorb an undue amount of engine power. The headlights, which are unusually powerful, are small and are equipped with magnetic tilting control from the steering column, the tilt is affected by rotating a hard rubber milled piece just below the horn button. The tail lights are double, one being a bright light which is automatically thrown in when the car is put in reverse to give a brilliant back light for driving backwards at night. There is also a lamp on the side of the car which illuminates a circle to the left of the car, making it possible to kill the glare of the headlights or to provide an illuminated area for working on tires, etc., at night.

Leading Distributers Named

The merchandising plan for the product, which has been worked out for the present, embraces a production of between 6000 and 6500 for 1921. Dealers have already been appointed for the New England, New York, Philadelphia, California and Chicago territories. A dealer for the Detroit territory will be appointed within the next 90 days. Deliveries to the dealers will be made during the last half of February. The New England dealer is the Fay-Allen Co.; the New York dealer E. B. Jackson, who recently resigned as sales executive for the Willys-Overland Co. The Philadelphia dealer is F. W. Foss; the Chicago dealer, Dayton Keith, and the California dealer, the Western Motors Co.

C. H. Wills & Co. was incorporated July 6, 1920, as a Delaware corporation. The officers of the company are C. Harold Wills, president; John R. Lee, vice-president; Kirkland B. Alexander, vice-president; Charles Morgana, vice-president; Frank P. Book, treasurer; Ferris D. Stone, secretary; George S. Anderson, assistant secretary and assistant treasurer. The financial matters of the company have been handled through the National Shawmut bank, Kidder, Peabody & Co., and F. S. Mosley & Co., all of Boston, Mass.

To Keep Stock From Market

No stock has been placed on the market or is it anticipated that any will be. The first unit of the factory has been completed and the heat treating plant is under erection at the present time. These two have a combined floor space of 221,400 sq. ft. The concrete foundations for the second factory unit have been laid and it will be completed after production has reached more than 75 per day, which is the capacity of the first plant. Production will start during February at the rate of 10 per day.

Maxwell Suit Filed to Aid Merger Plan

NEW YORK, Jan. 24—The creditors' suit recently begun in Federal district court in Detroit by the Jenks & Muirs Mfg. Co. against the Maxwell Motor Co. Inc., was filed for the purpose of carrying out the reorganization plan for the Maxwell and Chalmers companies through the transfer of the assets of the present company to the new corporation, it is learned from Maxwell attorneys.

The court is asked for an injunction restraining creditors from interfering during the pendency of the suit for the establishment of claims of creditors and assets. If the petition is granted, as it is confidently expected it will be, there will be no necessity for equity receivership proceedings preliminary to the reorganization and consolidation of the new companies which now are backed by ample working capital.

BOWSER OFFICERS CHANGE

FORT WAYNE, IND., Jan. 22—S. B. Bechtel, vice-president and general manager of S. F. Bowser & Co., Inc., manufacturers of gasoline and oil storage systems of this city, has announced several important changes in the executive positions of the company.

W. G. Zahrt, who has been treasurer and assistant general manager, has been named as vice-president and assistant general manager. The treasurership thus vacated has been filled by the appointment of D. G. Milligan, assistant treasurer. J. R. Matlack, who has been executive assistant, has been advanced to the position of assistant to the general manager. R. L. Heaton has been named as assistant to the general manager.

Turcat-Méry Goes Into Liquidation

Failure Surprises French Industry—Ballot to Make Special Sporting Car

PARIS, Jan. 15 (*Special Correspondence*)—One of the oldest of the French automobile companies, for it was established in 1899, the Turcat-Méry of Marseilles, has gone into judicial liquidation. The original capital of the company was 525,000 francs. At the beginning of 1920 the capital stood at 1,050,000 francs, but during the year it was increased to 2,100,000 francs. In June of last year new stock was issued and the capital increased to 3,000,000 francs. At the same time 2,000,000 francs worth of 6 per cent bonds were issued, and three months later another 1,000,000 francs worth of similar bonds were put out.

This failure comes as a surprise, for Turcat-Méry was looked upon as a very sound organization. The volume of business was not big, the output never exceeding 800 cars per year, but the firm enjoyed a good reputation. Leon Turcat, managing director of the company, is treasurer of the Paris automobile show committee.

The Ballot company is involved in the failure of the Turcat-Méry concern, for the cars of the latter company were all fitted with Ballot engines, and big quantities had been delivered before the liquidation went into effect. Ballot is also affected by the liquidation of Sizaire-Naudin, another old established automobile company, and by the financial difficulties of the Sigma company. This latter concern, which made use of Ballot engines and transmissions, has not gone into liquidation, but is in such financial difficulties that practically all production is stopped. Ballot has reduced his normal staff of 1200 to 100 men. It is stated on good authority that Ballot will shortly produce a special sporting, semi-racing type car of 122 cu. in. piston displacement. This firm being one of the biggest producers of engines for car assemblers, there is no intention of producing complete cars on a big scale, but activities will be confined to the special semi-racing type.

Berliet to Make Rail Truck

Berliet is negotiating with the French Government for the delivery of important quantities of narrow track locomotives fitted with gasoline motors. The truck motor will be used. This firm is trying to relieve its present financial position by the sale of all surplus stocks of raw material.

The Zenith Carbureter Co., after having cut down its staff at Lyons factory from 1200 to 900 men, announces that it expects to be at work with a full force within three or four weeks. The firm has produced a new carbureter, a small number of which have been delivered for experimental purposes.

Cuban Ports Tied Up, Exporters Warned

Mexico Best Latin-American Field Now for Cars, Says Southern Shipper

NEW ORLEANS, Jan. 21—Warning to manufacturers and exporters of automotive vehicles of all kinds, as well as to all American exporters of other manufactured products, to "go slow" on shipments to Cuba; to get payment for their shipments while the shipments are still in the United States, and to ship only by established steamer lines, rather than by "tramps," was issued today by L. J. Folse, Jr., of New Orleans, president of the Marine Forwarding and Shipping Co., a leading factor in Latin-American trade from all the Gulf ports, and a prominent official of the New Orleans Association of Commerce.

"Latin-America, with the unusual development of good roads as transportation aids now being done by many of the governments there, is becoming one of the best fields for the automobile, truck and tractor manufacturer and exporter, but if that manufacturer and exporter is not to meet with loss and often failure in those fields, he must study them carefully," said Folse.

"At the present time, Mexico is the best field for American exports of all kinds, including passenger cars, trucks and tractors, while only a few hundred miles to the east lies Cuba, probably the most dangerous and the worst field for all kinds of exports.

"Shipments of automobiles, trucks and tractors, along with other exports from the United States and other countries, are being refused by Cuban consignees and allowed to lie unprotected in lighters or on unroofed wharves, since the congestion in all the ports precludes movement of shipments to warehouses or to other protected places. This congestion is true of the outside ports as well as of Havana, and the Cuban importers, refusing to take out their consignments, naturally are not helping in this freight movement.

Should Avoid Tramp Lines

"Automobile exporters especially should be extremely careful, in making shipments to Cuba, to ship only by established steamer lines, which have terminal and warehouse facilities at Cuban ports, in which such shipments can be left in safety from thieves, and protection from the elements, until received by the consignee.

"Conditions in Porto Rico, on the other hand, are excellent. Money is more plentiful than it has been for some time, and there is no port congestion.

"It is in Mexico, however, that conditions, both financial and commercial, are the best for the automobile exporter of all the Latin-American countries. The paper money issued by the various revolutionary government has been virtually all absorbed, and gold and silver coins are in circulation, putting the country on what is practically a metallic basis, with the coinage intrinsically worth more than its nominal value. There is no congestion at the ports and labor troubles, which threatened for a while, have been eliminated. An unusually extensive policy of good-road building has just been inaugurated by the federal government."

S. A. E. Tractor Meeting Set for February 10

NEW YORK, Jan. 27—The annual tractor meeting of the S. A. E. will be held Feb. 10 in Columbus, Ohio, during the week of the National Tractor Show there. The program of the convention is as follows:

Technical Sessions, Hotel New Southern, 10 A. M. and 2 P. M.
E. A. Johnston, Chairman
John Mainland—Report of Committee on Pulley Widths and Speeds.
O. W. Sjognen—Nebraska State University, Tractor Test Results.
E. A. Johnston—Trend of Tractor Design.
D. L. Arnold—Report on Investigation of Plowing Speeds.
Columbus Dinner, Hotel Deshler, 7 P. M.
Fred Glover, Toastmaster.
SPEAKERS
W. H. Stackhouse, President, National Implement & Vehicle Association.
L. J. Taber, Master of Ohio State Grange.
J. B. Davidson, Secretary American Society of Agricultural Engineers.

Iowa Car Maintenance Exceeds Corn Value

DAVENPORT, IOWA, Jan. 22—Value of Iowa's 1920 corn crop, the greatest in the State's history, was $20,000,000 less than the cost of Iowa's automobiles for the same period, according to estimate prepared by L. A. Andrews of Ottumwa, president of the State Bankers' Association. Automobile registry fees alone, he pointed out, will amount to more than receipts from 270,000 acres of timothy seed and 134,000 acres of clover seed, and the total of spring wheat standing on 400,000 acres will lack $1,500,000 of registering State automobiles.

Last year 437,265 cars paid the State $7,414,548.98 in registry fees and dealers paid an additional $92,653.10 for their numbers. Upkeep of these cars ran to $260,000,000. The corn crop was valued at $222,686,000.

HOLT EMPLOYEES AGREE TO CUT

PEORIA, ILL., Jan. 22—Employees of the Holt Mfg. Co., after conference with officials, have agreed to accept a cut of 15 per cent in wages in thirty days. Wage scales at the time of closing the plant will continue during the month.

Manager M. M. Baker in announcing results of the conference said: "The men promise a 25 per cent increase in productivity and on our part we agree not to suggest any further wage reductions for a period of six months."

Big Future Trade Likely in Siberia

Promoter Would Have American Interests Send Representative to Study Territory

SEATTLE, Jan. 21—While there is to-day no possibility of doing any business because of the almost worthless level to which the ruble has descended and on account of the unsettled political conditions, American manufacturers of automobiles and tractors should join in sending a representative to Siberia at this time if they are to share in the tremendous trade that will develop when the big "opening up" occurs. This was the declaration of Waldemar Toritch, former president of the once powerful Timbermen's Association of Siberia and now connected with several enterprises in Siberia, who is on a brief visit to this country. Toritch left Vladivostok about six weeks ago.

British, French and other European manufacturers have trade investigators of a high caliber on the ground, and have had for some time, said Toritch. These representatives are laying the foundation for obtaining a generous share of the orders when it is possible to accept them. On the other hand, the visitor declared that American manufacturers appear to be entirely overlooking the urgency of being represented in Siberia now, despite the fact that no business is immediately forthcoming.

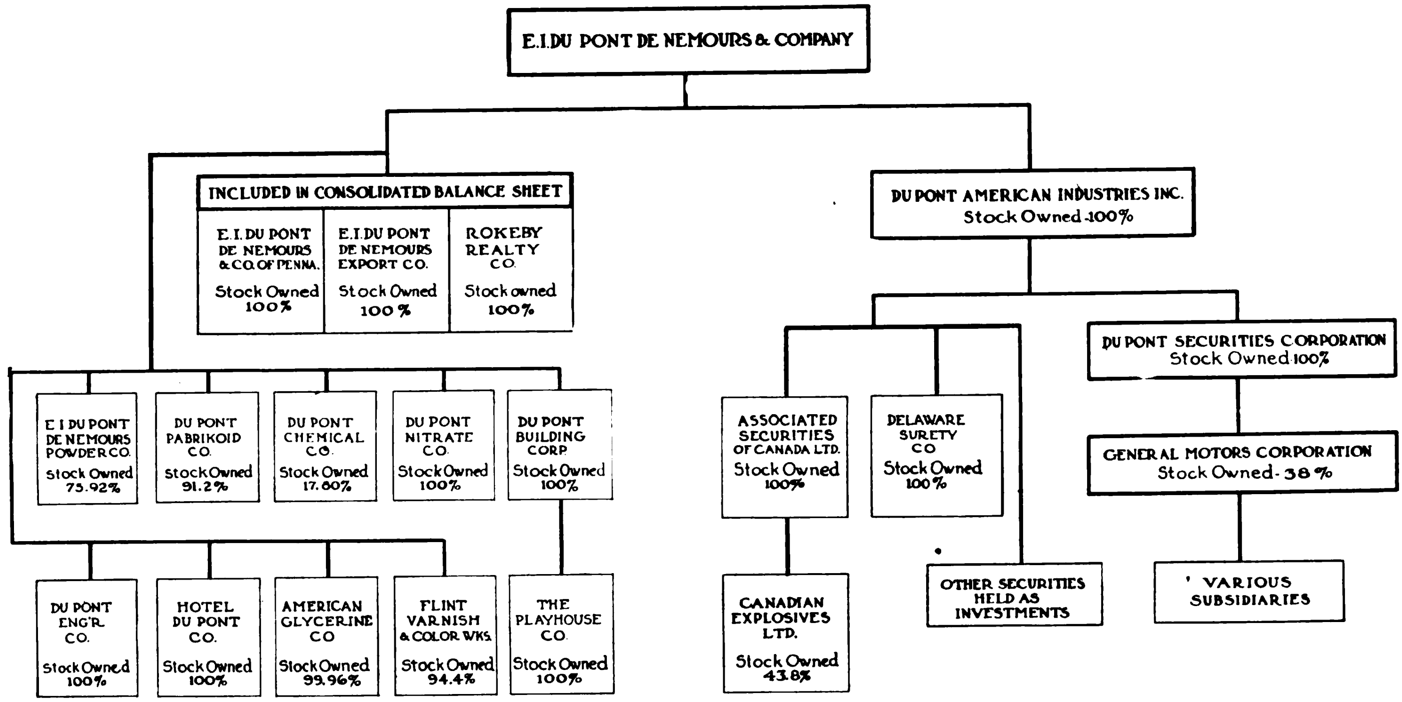
Because of the deteriorated state in which the railroads are in, there will be an enormous demand for automobiles of all classes in Siberia when trade can be resumed, said Toritch, and the Europeans are actively preparing to act as the suppliers.

Toritch has witnessed with marked interest the increasing use to which tractors are being put in the great lumbering industry of the western part of the United States, and believes that when the development of the timbering industry of Siberia is undertaken tractors will be in great demand. Toritch declared that the forest stands in four of the leading provinces in eastern Siberia covers 156,377,725 acres. At the present time Siberia is not consuming 1 per cent of its standing timber. There is not now a single mile of logging railroad in Siberia, said Toritch, so that forests situated over sixteen or seventeen miles from the water are absolutely untouched.

WOULD BUY CHILLICOTHE PLANT

CHILLICOTHE, OHIO, Jan. 24—Stockholders of the Chillicothe Rubber Co. have been asked to consider a proposition made by the Ultimate Tire & Rubber Co., Cleveland to take over the plant here. The Cleveland company, capitalized at $2,000,000, has sold a large part of its stock but has no plant of its own at present. Another meeting of the Chillicothe stockholders will be held late this month to vote on the question.

Main Holdings of E. I. du Pont de Nemours & Co.



This chart shows the main ramifications of the DuPont interests where the various members of the family have banded together but it does not indicate in any way the investments of the various members of the family as individuals. These investments run far into the millions and make the men who now control the General Motors Corp. one of the strongest groups of financiers in the world

Eisemann Consolidation With Recording Pends

DAYTON, OHIO, Jan. 24—Negotiations for the consolidation of the Recording & Computing Co. of this city and the Eisemann Magneto Corp. of Brooklyn under the name of the Ohmer Corp. have not yet been completed according to Will I. Ohmer, president of the Recording Co. The plants of the company here were used for war work and when hostilities ceased, they decided to go into the production of automotive parts. One of the most important of these will be magnetos. Other devices will be a combination magneto and generator for trucks, a starting motor and a generator. Considerable difficulty has been experienced in obtaining castings and machinery.

The Eisemann magneto is used as standard equipment by more than 125 automotive companies. It also manufactures other devices for motor vehicles. The company has no factory of its own but occupies under lease 100,000 sq. ft. in one of the Bush Terminal buildings in Brooklyn. It has service stations all over the United States, Cuba, South America, the Philippines and Hawaii.

SINGER LIABILITIES $103,998

NEW YORK, Jan. 21—Schedules in bankruptcy filed by the Singer Motor Co. of Mount Vernon disclose liabilities of $103,998, of which $42,066 are secured claims. The assets are listed as $114,460, book value. The assets are divided as follows:

Stock, $42,621; chassis held as security for loans, $11,973; apparatus, $17,596; furniture and fixtures $2,184; stocks, at par, $2,600; deposits, $35,284, and accounts, $2,199. Among secured creditors are Columbia Trust Co., $20,000, and Clinch Valley Coal & Iron Co., $19,556. Among those unsecured are Mount Vernon Trust Co., $8,000; Pacific Bank, $6,926, and Westinghouse Electric & Mfg. Co., $4,871.

Continental Motors Shows Higher Earnings

DETROIT, Jan. 21—The net profits of the Continental Motors Corp. during the fiscal year ending Oct. 31, 1920, were $3,567,504 compared with $3,425,725 in 1919. Including the surplus, the balance was $7,395,202 compared with $4,981,335 the year before. After deducting dividends, the net surplus was $6,345,309 as against $3,827,698 the year before. The total sales were 15½ per cent in excess of the previous year. The orders on the book at close of the fiscal year totalled $53,584,220 or 64 per cent more that at the end of the previous year.

SAGINAW PRODUCTS PICK UP

SAGINAW, MICH., Jan. 22—The various plants which make up the Saginaw Products Co. and are a part of the General Motors Corp., are gradually although slowly resuming operations. In a statement by General Manager George H. Hannum, he said there are about 400 men, 25 per cent of the normal number, now working at the motor plant; 100 or about 20 per cent, at the malleable plant; about 10 per cent of normal force at the foundry, while the Jacox or steering gear plant is likely not to reopen until Feb. 1, or even the middle of the month.

To Show New Renault at New York Branch

NEW YORK, Jan. 25—G. Baldenweck, general manager for Renault automobiles in America, announces that he will have on exhibition at New York showrooms next week a 10 hp. Renault car.

This car was recently referred to in a cable from Paris to AUTOMOTIVE INDUSTRIES as containing some features of the American Ford. Baldenweck says that this is not correct, also that the statement that the model has been withdrawn and a 12 hp. substituted, was an error. In this connection, Baldenweck writes:

"Referring to your article which was published Nov. 4 on the subject of Renault cars, I am directed by our factory in Billancourt, France, to advise you that our 10 hp. car is not, by any means or design, either a copy of the Ford automobile or a copy of any other car. It was completed and delivered in France a short while ago and there are now over 5000 of these cars in circulation, not only in France but in foreign countries, and this is our best proof that the car in question is giving all the satisfaction expected to motorists.

"Further, instead of upholding the manufacture and production of this car, we are proceeding normally to its construction and we have the approval of our customers, who have sent us numerous orders, not only direct to our plant, but through our various agencies."

It may be interesting to know that there is on exhibition at the New York show rooms the first Renault model built by the company.

No Barrier Found to Tire Sale Here

A. E. F. Stocks Now Offered to American Dealers—Surplus Totals 360,000

NEW YORK, Jan. 26.—The lack of legal provisions forbidding the re-importation into this country of surplus army tire stocks in France, probably means, according to General Manager Viles of the Rubber Association of America, that all of these tires intended for army use abroad soon will be landed in America and offered for sale to American buyers.

Cable despatches have indicated that there were approximately 200,000 pneumatic tires and 160,000 solids, and a presumably large supply of inner tubes. Of this number, Viles said, all but about 55,000 pneumatics and 80,000 solids had been bought by representatives of American jobbing syndicates to a recent date and the remainder have probably been purchased by now.

Thousands have been sold already to American tire dealers by the jobbing syndicate, operating in New York and Newark, N. J. The tires are of five standard American makes. Though they are unused, they are not new in the sense that they have been manufactured several years and consequently have suffered deterioration through aging. Manufacturers have declared their intention to deny the usual adjustment privileges.

Manufacturers do not anticipate any particular slump in the market owing to the absorption of this supply, but there has been considerable annoyance expressed that there has been no legal barriers to prevent this surplus being sold here.

INLAND ACQUIRES SHURNUFF

ST. LOUIS, Jan. 22—The Inland Machine Works has absorbed the Shurnuff Mfg. Co. and will continue the manufacture of its products which include a spark plug, combination manifold, grease retainer, runningboard support and a heater. Former prices will be continued. Sales are made only through bona fide jobbers.

Stockholders of the Shurnuff company are now stockholders in the Inland works, and two directors of the former company are now directors on the Inland. One of these is John F. Shuford, well known to the jobbing trade.

AMERICAN METAL TO BUILD

MILWAUKEE, Jan. 24—In view of substantial improvement in the demand for its products, and more favorable conditions in building construction and equipment markets, the American Metal Products Co. has decided to proceed immediately with the erection of a new foundry and machine shop in West Milwaukee. The work was projected about six months ago but held in obeyance until now. The main shop will be 80 x 225 ft., and equipped with new electric furnaces for manufacturing Ampco bronze bars, rounds, castings, etc., under patented processes. Officers of the company are: President, George F. Staal, city engineer of Milwaukee; vice-president, W. J. Eberle; secretary-treasurer and general manager, Carl J. Zaiser.

Blekre in Production on High Grade Tire

ST. PAUL, MINN., Jan. 26—Production has been started in the new plant here of the Blekre Tire & Rubber Co., organized with a capitalization of $4,500,000 to manufacture high grade cord and fabric tires and tubes. The plant has a capacity of 2000 tires a day and will employ 250 operatives. The company will devote itself entirely to high grade product and will not enter the medium grade field.

The formation of the company is the outcome of the growth of a small tire jobbing business started by E. O. Blekre, three years ago in Sioux City, Iowa. Through the expansion of this business the Blekre Tire & Rubber Co. was formed to manufacture and market its own product and St. Paul was selected as the manufacturing site.

Officers of the company are E. O. Blekre, president; S. E. Blekre, vice-president and treasurer; G. W. Wells, secretary; S. A. Rheinstrom, vice-president and general sales manager; G. O. Ludcke, advertising manager, and W. E. Greer, superintendent.

ERDMAN-GUIDER GETS GOING

SAGINAW, MICH., Jan. 22—Erdman-Guider Co., which operates a large body making plant here and another in Detroit, is preparing to increase its production, due to the satisfactory business transacted at the show by some of its customers. The company employs normally about 350 men, the local plant giving employment to more than half. The company specializes on closed bodies and its total production capacity is about 5000 for its two plants.

COTTON STATES RUBBER FORMED

ATLANTA, Jan. 24—With a capitalization of $500,000 and authority to increase to $2,000,000, the Cotton States Rubber Mfg. Co. has been incorporated here by J. B. Anchors, R. W. Ragin and G. J. Reuter. The company states in its petition for a charter that it will manufacture automobile tires and tubes.

WILSON FOUNDRY TO RE-OPEN

PONTIAC, MICH., Jan. 24—The Wilson Foundry & Machine Co. expects to resume operations not later than the first week in February, according to the statement of the vice-president and general manager D. R. Wilson. Inasmuch as this concern is one of the units of the Willys-Overland Co., it probably means an early increase in activities at the Willys-Overland in Toledo.

METAL MARKETS

SOME of the smaller interests among the independent steel producers are sounding consumers with a view to ascertaining whether price concessions would lead to the placing of orders without delay. Steel men, large and small, are unwilling to cut prices if their doing so results merely in lowered quotations without increasing buying activity. Sales managers are, therefore, exhausting their resources of diplomacy to make certain that tonnages are actually ready to be ordered before they compete actively for the business and, in a market condition like the present one, competition revolves almost solely around the price. A cut of $3 a ton under the general market was secured in this way on a tonnage of sheets bought by the Standard Oil Co. a few days ago. In the case of the smaller steel finishing plants the human element enters strongly into their anxiety for sufficient orders to keep their plants at a fair rate of operation. In a large plant it is relatively easy, even in a period of quasi-idleness, to keep the vital parts of the organization intact, whereas the burden of "overhead," in keeping skilled overseers, superintendents and foremen on the payroll, when the wheels are not turning, is considerable in the case of small plants. Some of the automobile sheet mills in the Ohio valley, however, are "sitting tight" in the matter of prices for another reason. These are the sheet makers who depend upon others for their supply of bar stock. They contend that, if they have to pay $47 for sheet bars, they must get twice as much for finished sheets, or a base price of 4.75c. instead of the prevailing quotation of 4.35c. So they are seeking to bring all possible pressure to bear on sheet bar mills to lower their prices. Odd lots of furnace coke are reported to have been sold in the last few days at as low as $4.50, which marks another recession of 50c. This should serve to expedite further re-adjustment in the pig iron market, which remains in much the same position as last week, offers of No. 2 foundry at $30, valley, continuing with occasional reports of odd tonnage sales at below that level.

Pig Iron—Automotive plants continue to operate largely on old reserves, and furnaces have been asked to hold off a few weeks more before resuming shipments on suspended tonnages.

Steel—Cold-rolled strip steel plants operate largely on old orders on which suspensions had been requested. No marked quickening in activity is looked for until automotive consumption increases. Although reductions on structural and boiler rivets have been announced, quotations on rivets used in the automotive industries remain nominally unaltered, but the market for rivets, as well as bolts and nuts, may be characterized as very easy.

Aluminum—The sole American producer's spot quotation for 50-ton lots of 98 to 99 per cent virgin ingots is now 28c., and for No. 12 alloy 27.30c. These prices denote an average reduction of ¼c. a lb. There are reports in the "outside" market that some automotive interests, apprehensive of an advance in import duties, have taken on some of the imported metal that was offered at 22½c.

Copper—In spite of curtailed production and some hand to mouth buying, the heavy surplus is being added to daily. In other words, there is still more copper produced than consumed. Hence the market's weakness.

Brass—The leading interest has reduced, effective January 20, its extras on a number of products 25 per cent. The War Department will re-offer 47,751,838 lb. of cartridge case brass, having canceled an award of this material recently made.

FINANCIAL NOTES

Martin-Parry Corp. has declared the regular quarterly dividend of 50 cents a share, payable March 1. Net income of the company for the ten months ended Oct. 31, 1920, was $378,000 after all charges, including Federal taxes. The company has current assets of $1,672,000, of which about $126,000 is cash in bank. Current liabilities are about $10,000. There are no outstanding notes and all inventories have been written down to present market values.

McCord Mfg. Co., Inc., reports 1920 sales as $15,257,672 and net earnings before Federal taxes, but after inventory adjustments, above $802,000. The great bulk of the inventory stands as sold material, therefore writing down will be very small. Operations were two-thirds of normal in November, but only 40 per cent in December.

Standard Die Casting Co. of Milwaukee has been incorporated with a capital stock of $100,000 to engage in the manufacture of dies, die castings and similar articles. The owners are the principal stockholders and officers of the Charles Jurack Pattern Works.

Lumen Bearing Co. will increase its capitalization from $200,000 to $500,000, of which $100,000 will be issued to stockholders as a stock dividend of 50 per cent. The balance of the new issue is to be used to take care of expanding business.

Lee Rubber & Tire Co. reports earnings for 1920 before deducting $225,000 dividends were about $510,000, without taking into account inventory write-off. On Dec. 31 the company owed banks $400,000 and had over $300,000 cash in banks.

Sterling Motor Truck Co. of Milwaukee, manufacturer of Sterling trucks, has increased its authorized capitalization from $250,000 to $1,000,000. Arthur C. Wollensak is chief engineer.

Charleston Steam Tractor & Truck Mfg. Co. has filed notice of an application to change its name to the Automoto Mfg Co., and to increase its capitalization from $1,000,000 to $2,000,000.

King Motor Car Co. has about $1,500,000 net assets with no bonded indebtedness, no notes out, and only a few small bills unpaid, according to General Manager Weber.

Kelly-Springfield Tire Co. has declared a quarterly dividend of $2 a share on the 8 per cent preferred stock of the company, payable Feb. 15.

Miller Rubber Co. gross sales in 1920 were $32,891,670.22; an increase of $5,775,081.89 over 1919, or 21 per cent.

Federal Motor Truck Co. has passed its monthly dividend.

Hamilton Motors Add Two New Truck Models

GRAND HAVEN, MICH., Jan. 22—Two new models are announced by the Hamilton Motors Co., a 1-ton speed truck and a 3½-ton truck. The 3½-ton model is very similar in design to the 1½ and 2½-ton Apex trucks, the only difference being in the dimensions of parts. It comprises a Buda 4½ x 6-in. engine, a Fuller 4-speed transmission amidships, a Torbensen rear axle with external service and internal emergency brake, a Shuler front axle, Blood Bros. universal joints and propeller shaft, G. & O. radiator, Stromberg carbureter, Eisemann magneto, Auto-Lite generator and Lavine steering gear.

The frame is of 7-in. rolled channel steel, ¼ in. thick and with 2¾-in. flange, and is suspended on half-elliptic springs. The wheelbase is 160 in., the front tread 65 in. and the rear tread 67 in. Wheels are of the wood artillery type, 36 x 5 in. front and 36 x 10 in. rear. The loading space is 168 x 72 in. The standard equipment includes a driver's seat, electric generator, electric head lamp, front fenders, tool box, tools, jack and Alemite grease outfit. The truck will develop a speed of 22 m.p.h., it is claimed.

On the 1-ton speed model, a Lycoming 3½ x 5 .in. engine is used, together with a Borg & Beck clutch, Muncey transmission, Torbensen axles, Lavine steering gear, G. & O. radiator, Stewart vacuum feed, Stromberg carbureter and Auto-Lite starting and lighting equipment. The frame of this model consists of 4-in. rolled channels, and is supported by half-elliptic springs both front and rear. The wheelbase is 130 in. and the tread the standard 56 in.

The 3½-ton model lists at $3,975 and the speed model at $1,695, both for chassis with seat.

Commonwealth Directors Re-elected to Positions

NEW YORK, Jan. 24—Directors of the Commonwealth Finance Corp. were reelected by large majorities at the annual meeting of stockholders. This is regarded as a vindication of the management of the company in the face of an attempt by one faction of the stockholders to have the present management ousted. It is considered probable that the temporary receivership, against which the company was granted a stay, soon will be lifted. After their election the directors elected the following officers: President, Henry D. Tudor; vice-presidents, Charles C. Dickson, Charles W. Thomas and Theodore L. Weed; secretary and treasurer, N. A. Merritt. The directors include the officers and Harry L. Burrage, George McAneny and Karl Goldsmith. The board is the same except that Weed takes the place formerly held by Ormsby McHarg, who instituted the legal proceedings resulting in the receivership and who preferred charges of malfeasance against the present management.

POWELSOHN DEBTS REDUCED

ROCHESTER, Jan. 24—Stockholders of the Powelsohn Foundry & Machine Co., Inc., manufacturers of automobile valves, pistons and wrist pins are apprised of the financial condition of the firm in a report just filed by the committee appointed at a meeting of creditors. According to figures submitted, the accounts payable on Oct. 1 were $38,953.29, and notes payable totaled $36,006.71. On Nov. 1 the accounts payable totaled $17,813.67 and the notes payable, $18,857.57.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Jan. 27—The stock market last week was irregular, with a downward tendency the latter part of the week after withdrawal of professional support. The bond market, on the other hand, gave indications of continued strength. There was a general advance, with some high grade bonds gaining as much as four or five points. Liberties and tractions were the most active issues. The new $30,000,000 8 per cent Belgian Loan was quoted last week on a "when issued" basis at a full point above par. Continued improvement in bond prices, which is generally expected to result from easier money, may be checked by further flotation of high-coupon-rate foreign issues, of which there are said to be a number in prospect. The foreign exchange market was the most prominent of the speculative markets.

The removal in Canada last week of the embargo on the importation of foreign held securities is significant, in that foreign held Canadian securities may form the medium of payment for Canadian exports, thus serving in a measure to divert Canadian trade from the United States to Great Britain, where Canadian securities are extensively held.

The recall of funds by interior banks and the continued withdrawal of Government funds were probably responsible to a great degree for the hardening of money rates last week. This is reflected in the large rediscounts and the decline in reserves of the New York Federal Reserve Bank. Call money, which had ruled at 6 per cent earlier in the week, rose to 7 per cent for renewals on Thursday and has since continued at that figure. The time money market was quiet with a 6 per cent rate quoted for all maturities up to six months. This rate compared with 6 per cent for maturities up to five months and 5½ to 6 per cent for six months' paper the week before.

A decline in the reserve position of the New York Federal Reserve Bank was partly a result of an increase in reserves held for private banks and of withdrawals by interior institutions. Gold reserves declined $37,495,000, and total cash reserves declined $36,001,000. Total bills on hand increased $50,372,000, and total earning assets increased $37,734,000. Federal Reserve notes in circulation declined $7,096,000.

The Federal Reserve banks as a whole continued the recent marked improvement in reserve position. Federal Reserve notes in circulation declined $44,181,000. The actual circulation at $3,115,310,000 was $289,600,000 less than it was only four weeks ago. Total gold reserves increased $10,315,000. As a result, the ratio of gold reserves to Federal Reserve notes in circulation, after allocating 35 per cent against net deposits, increased from 54.8 per cent to 55.6 per cent. While total earning assets declined $27,016,000, net deposits increased $33,061,000.

MEN OF THE INDUSTRY

Fred L. Good has assumed new duties as general sales manager of the Ogren Motor Car Co., Milwaukee, manufacturing the Ogren. Good retires as sales manager of the Wisconsin Automobile Sales Co., state distributer of the Jordan, after two years' service. He has been connected with the automotive industries for twenty years, having been associated in engineering capacities with Ford and Cadillac.

W. D. Crouch, formerly in charge of sales for Robertshaw temperature controllers in industrial plants, has been made general sales manager of both the domestic and industrial departments. The headquarters of the sales manager of the industrial department have been moved from New York to Youngwood and consolidated with those of the domestic department. John A. Robertshaw has been appointed New York representative and will have charge of Eastern interests.

C. C. Clay, for the past year sales manager of the Samson Tractor Co., Janesville, Wis., has retired to resume his previous connections with the Chevrolet Motor Co. of Atlanta. He is succeeded at Janesville by Hugh M. Craig, with the title of acting general sales manager, pending a permanent appointment. Craig has been assistant to Clay, and he is a nephew of J. A. Craig, president and general manager of the Samson company.

David Rosenbach, formerly president of the Motor Equipment Co., which recently discontinued business, has been appointed general field secretary of the Automotive Equipment Association. He was a jobber for five years, sales manager for the Rayfield carbureter for many years, and for four years was president of the Overland Sales Co.

C. R. Lester has resigned as general service manager of the Packard Motor Car Co., taking effect Jan. 17. Lester has occupied this important position for a number of years and has been largely instrumental in building up the system and personnel of the Packard service organization. He is one of the pioneers in the automobile business.

Hiram Walker has been appointed chief engineer of the Chandler Motor Car Co. Walker has been with Chandler for several years and his many friends will be pleased to learn of his promotion. He succeeds J. V. Whitbeck, who will now devote all his time to the Cleveland Automobile Co., he being president of that company.

Edmund T. Boland, formerly works manager of the Kissel Motor Car Co., Hartford, Wis., and more recently in charge of operations of the Clintonville (Wis.) Tractor Co., has become associated in a similar capacity with the Theodore Armleder Co., Cincinnati, manufacturer of Armleder motor trucks.

John N. Mowery has been made general manager of the Worcester Pressed Steel Co. He has had a wide manufacturing experience, having formerly been plant engineer with the Chester Shipbuilding Corp. and more lately connected with the McDougall-Duluth organization.

F. W. Fenn, secretary of the motor truck committee of the National Automobile Chamber of Commerce, delivered two lectures this week to the seniors of the University of Michigan, who are taking the course in transport engineering.

Hugh R. Corse has been made sales engineer of the Lumen Bearing Co. For the past six years he has been general sales manager of the Titanium Bronze Co., and previous to that had been manager of the Lumen office in Detroit.

Robert M. Eames has been appointed general sales manager of the Bryant Electric Co. to fill the vacancy caused by the resignation of Frank V. Burton. Eames has been active in the sales organization of the Bryant company for fifteen years.

Ernest N. Culver, who during the last three years has been division manager of the Willys-Overland Co. in charge of the southern division with headquarters at Atlanta, has been promoted assistant sales manager.

J. G. Meibrod, during the past four years foreman in direct charge of the Titanium Bronze Co. foundry, has made connections with the Hills-McCanna Co., Chicago, and assumed charge of its foundry Jan. 24.

H. M. Daniels, who has just returned from eighteen months abroad in the interest of the Four Wheel Drive Automobile Co., Clintonville, Wis., has been appointed manager of the New York branch of the company.

A. S. Hetzell has been appointed general sales manager of the Knox Tire & Rubber Co., Mt. Vernon, Ohio. Hetzell was formerly connected with the Diamond Rubber Co. and latterly with the Republic Rubber Co.

R. I. Pierce has resigned as supervisor of production and materials of the Gramm-Bernstein Motor Truck Co., effective Feb. 1. Pierce will join the sales organization of the Holland Furnace Co., Lima, Ohio.

S. Y. Tidd has been elected president of the New Tread Tire Co. of Columbiana, Ohio; C. R. Calvin, secretary and treasurer, and Eric P. Altenburg, vice-president and general manager.

Charles Froesch has resigned as chief engineer of the S. W. Merritt Co., New York, to become associated with William E. Kemp, New York, carburetion specialist.

Paul Fitzpatrick, vice-president of the General Motors Acceptance Corp., has returned from a trip abroad.

E. B. McKay has been elected vice-president and general manager of the Inland Rubber Co., Chicago.

W. C. Anderson Resigns as Ford Representative

DETROIT, Jan. 26—Warren C. Anderson, director of the five Ford Motor Co. corporations in Europe and chief representative of the American company, with offices in London and Paris, resigned to-day. Both Edsel Ford and Henry Ford were in conference with Eastern bankers, so the resignation was not tendered personally but laid on the desk of Edsel Ford, president. No reason was given for the resignation.

Huron Truck Prepares for Improved Business

BAD AXE, MICH., Jan. 22—The annual meeting of the directors of the Huron Truck Co. resulted in the re-election of the present officers and directors. The officers are: President, F. W. Kinde; vice-president, W. R. Lyons; secretary, C. C. Henny; treasurer, Fred M. Cross. The board of directors consists of these officers and former Governor A. E. Sleeper, George L. Whitney, John G. Clark, Fred M. Cross and John Ryan.

INDUSTRIAL NOTES

Arrow Pump Co. has been organized with headquarters at 1438 Washington Boulevard, Detroit, to manufacture a full line of small pumps for automobile, marine and tractor engines. The company is headed by F. M. Cobb, for several years president and general manager of the Fulflo Pump Co. Other officers of the same company are associated with him in the new enterprise. The capacities of the pumps to be made at present range from 4 quarts to 25 gallons a minute.

Detroit Consolidated Sales Co., Inc., has been formed in Detroit to handle the sale of Universal Tool Co. products to the wholesale trade in Minnesota, Iowa, Missouri, Arkansas, Louisiana and all states east. Officers of the company, most of whom were formerly connected with sales end of the Universal company, are E. H. Herman, president; C. H. Hinckley, vice-president; J. F. Nebrick, treasurer, and C. C. Weisblum, secretary.

General Electric Co. has bought the lamp and wire plants of the Independent Lamp & Wire Co., and it is thought the latter company will go out of business. One-third of the Independent company stock was owned by the General Motors Corp., which took about 10 per cent of its lamp output.

General Motors Corp. has bought an entire city block in Saginaw almost adjacent to the Jacox plant, which is a General Motors unit and which makes steering gears. While for the time being it is not expected that anything will be done to the new property, the site will eventually be used for the erection of a large addition to the Jacox plant.

Roller-Smith Co. has appointed the J. E. Dilworth Co., Memphis, as its representative in western Tennessee, eastern Arkansas and northern Mississippi. The electrical department of the Dilworth company is in charge of E. M. Greeson, formerly associated with Fairbanks, Morse and Sanborn Electric Co.

Seymour Laboratories Units, Inc., has been adopted as the new corporate style of the W. E. Seymour Mfg. Co. of Milwaukee. Walter E. Seymour is head of the company which is incorporated with a capital of $250,000 to manufacture piston rings and other automotive parts and specialties.

Service Motor Truck Co. of Wabash, Ind., has notified the Commercial Intelligence Branch of the Department of Trade and Commerce that it has purchased fifty acres of ground in London, Ont., and expects to build workshops for the manufacture of motor trucks in the spring.

Universal Tool Co., Inc., has moved its sales, service and executive offices from Detroit to the new factory at Garwood, N. J.

Ward La France Truck Corp. has established a direct factory branch in Chicago in charge of former Sales Manager G. E. De Long.

Four Drive Tractor Co., Big Rapids, Mich., has passed into the control of Dr. G. H. Lynch and John E. Bergelin.

MILES BUYS NEW BUILDINGS

CHICAGO, Jan. 21—The Miles Piston Ring Co., manufacturer of piston rings for about fifteen automobile companies, has acquired property on the South side of this city improved with a one and two story building. The Gill Piston Ring Co. has recently completed an addition to its plant here and has plans for further additions next year.

Calendar

SHOWS

Jan. 29-Feb. 4 — **Chicago, National Passenger Car Show, Coliseum, Auspices of N.A.C.C.**

Jan. 31-Feb. 5—London, Ont., National Automobile Show of Western Canada, London Chamber of Commerce, Armories, T. C. Kirby, Mgr.

Feb. 5-12—**Minneapolis, Annual Automobile Show, Minneapolis Automobile Trade Ass'n.**

Feb. 7-12—Columbus, National Tractor Show, Columbus Tractor & Implement Club, Ohio State Fair Grounds.

Feb. 7-12—St. Louis, Annual Automobile Show, St. Louis Automobile M'f'rs & Dealers' Ass'n, Robt. E. Lee, Mgr.

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n, Armory, Arthur Fifoot, Mgr.

Feb. 12-19—Kansas City, Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, Secy'.

Feb. 21-26—Salt Lake City, Annual Automobile Show, Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatzky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Feb. 7—**Delhi, India, Delhi Motor Show.**

Mar. 23-28—**Witwatersrand Agricultural Show including machinery and motors sections.**

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

October—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

CONVENTIONS

Feb. 2-4—**Chicago, First Annual Meeting, Automotive Electric Service Assn. Hotel La Salle.**

May 4-7 — **Cleveland, National Foreign Trade Council.**

Oct. 12-14, 1921—**Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.**

Roads Bureau to Show Practicability of Tests

WASHINGTON, Jan. 24—For the second time in its history, the Federal Bureau of Public Roads will make an elaborate exhibit outside the National capital when it stages a demonstration of its work at the American Good Roads Congress to be held at the Coliseum in Chicago, Feb. 9 to 12 next. The bureau is preparing to ship considerable equipment to Chicago and several of the bureau officials will occupy prominent places on the program.

Features of the government exhibit will be actual demonstrations by the Division of Tests in the conduct of the impact tests that the bureau is using to determine the ability of different soils to sustain roads and to measure the amount of wear on road surfaces caused by heavy traffic. Owing to the fact that moisture in the underlying soil is the principal cause of road failures, the actual subgrade tests and investigations which will also be conducted by the bureau at Chicago, showing how the movement of water in different soils can be controlled and road failures reduced, will be a big feature. The bureau will also conduct tests of road-building materials.

OHIO DISMISSES HIGHWAY HEAD

COLUMBUS, Jan. 24—Major General George W. Goethals, builder of the Panama Canal and formerly Quartermaster-General of the Army, spent a day in Columbus conferring over the reorganization of the Ohio Highway Commission. Considerable attention is being given to the reorganization of the Ohio Highway Commission and the first step in that direction was the dismissal of A. R. Taylor, highway commissioner and the naming of T. S. Brindle, chief engineer in the department, acting commissioner until the reorganization plan is decided upon.

Credit Men's Bureau Aids Car Financing

NEW YORK, Jan. 22—The Auto Financing Credit Men's Association, Inc., organized in New York a year ago to protect members and to assist dealers in improving the quality of their time payments risks, now has twenty-five members in the New York territory and seventeen in Chicago, who did $256,597,891 of business in 1920. The association has been working quietly for the past year, maintaining a paid secretary and exchanging information regarding accounts to prevent duplication of loans on a single security. At the same time it has been sending out periodic letters to dealers who are clients of its members, giving general information about credit risks. The membership includes some of the largest acceptance corporations, including two controlled by automobile interests.

WINDSHIELD PATENT UPHELD

NEW YORK, Jan. 24—Federal Judge Hand has granted to Theodore B. Nisbet, John O. Hofbauer and Anton Valerius a perpetual injunction restraining the Perkins Tonneau Windshield Co., Inc., from the manufacture or sale of windshields embracing the claims in a patent granted to Hofbauer in 1912. The court has appointed a commissioner to assess the damages due the plaintiffs under the infringement which the court recognizes.

Congress Drops Fund for Horsepower Study

WASHINGTON, Jan. 22—Engineering research into the problems of standardization of horsepower of motor trucks and tractors, as contemplated by the Bureau of Roads in co-operation with automotive manufacturers, will be abandoned unless the Senate Appropriations Committee restores the item for $100,000 which the House Committee struck from the Agricultural Appropriation Bill. Other reductions in the appropriations for this Federal agency will undoubtedly force them to revise their extensive plans for scientific inquiries into motive power and highways.

Truck and tractor manufacturers had requested the Bureau of Roads to undertake these investigations among farmers and other users of automotive farm equipment. The inquiry was intended to cover the construction, capacity, use and operation of farm implements, farm machinery, motor trucks, tractors and motive power for farm purposes. Only a portion of this fund would have been devoted exclusively for inquiries in this field as the research was to have been extended to other phases of rural engineering problems.

NEW YORK GETS DEVICE BILL

ALBANY, Jan. 24—Asemblyman Martin has introduced in the Legislature a bill which would require every motor vehicle to be equipped with automatic lights showing by color or other means whether it is moving or stationary. The bill would require use of words or lettering by day to show whether or not the car is in motion. It is significant the requirements fit a patented device.

VOL. XLIV NEW YORK—THURSDAY, FEBRUARY 3, 1921 No. 5

Optimism and Returning Business in Evidence at Chicago

Many car manufacturers give releases to parts makers. Forecast of 1921 production is 60 per cent. of 1920 figure. Early attendance at show exceeds previous records. Manufacturers and dealers discuss policies. Sales and prospects very encouraging.

By J. Edward Schipper

CHICAGO, Feb. 1.

IT would be impossible for even a conservative observer to leave the Chicago Automobile Show, which is being held at the Coliseum this week, without becoming imbued with the spirit of sane optimism which prevails among the attending manufacturers, parts and material makers and dealers. These men came here with the hope of getting business and practically all are reporting more than they expected. This spirit is reflected throughout the entire gamut of show incidents. The attendance is larger than at any previous Chicago show, running, as this is written, fully 10 per cent ahead of that of a year ago.

The sales on the floor have exceeded the most optimistic predictions and while, during the early part of the week, the larger part of the sales are the result of campaign work, conducted before the show opened, there are a considerable number of new sales. One assembled car maker in the $2500 class reports eight sales on the floor during the first three days, three being to persons not on the prospect lists.

To properly appreciate the satisfaction with which the business being done at the show is regarded through the trade, it is necessary to realize what it was hoped to accomplish at this show. Never has the difference between the New York and Chicago shows in this regard been brought out as strikingly as this year. Most manufacturers and others left the New York show no wiser than they went. Parts makers, as a rule, were unable to get schedules from the manufacturers and very few of the car manufacturers were able to get sufficient information from their distributing organizations to formulate a policy for the year. At the close of the New York show all eyes were turned toward Chicago, with the feeling that the show there would enable a closer estimate of the year's business.

As a consequence everybody is here. The material manufacturers are represented more strongly than ever before. Foundry, forge shops and mill men are here, as well as car distributers and makers. They came to feel the pulse of the industry, as well as to obtain actual orders. The result is that, because all branches of the industry are in attendance, it is possible to get a more tangible view of the manufacturing situation for the next three months than has been possible since the present phase of business conditions was entered.

With the exception of perhaps five of the large man-

ufacturers, who have internal conditions in the way of re-organization of finances and personnel to face or who, because of a previous period of forced production, have an unusually large stock of cars in distributers' hands, the car manufacturing schedule for the next three months will average 60 per cent of that for the same period in 1920. Releases to parts manufacturers have started and are being given on this basis. It is almost impossible to make any definite predictions because of the position of three or four of the largest producers. But gathering together all the bits of information available, a production estimate of 1,300,000 for 1921, looks conservative. While the selling wave began to spread early in January, there is no question that it has been accelerated by the Chicago show.

The enthusiasm of dealers who came here in a keenly critical frame of mind to get a line on business conditions tells the story far better than it can be put into words. A shortage of cars in the spring has been predicted and talked of by over-optimistic dealers for the past two months, but it is doubtful whether there will be any general shortage. At the same time it is very likely that certain makers who have been especially conservative in their manufacturing policy during the dull period, will confront a delayed delivery condition.

The supply of unsold cars in the country has been over, rather than underestimated. The rumor crop which has been exceptionally good during the past three months, has been responsible for exaggerated estimates of the numbers of cars on hand. One of the greatest benefits of the show is that it enables the dealers from various parts of the country to compare notes and get these stories out of their systems. It is true that four or five manufacturers have overstocked dealers but beyond this there is not much slack to take up during the time required to get into production. It requires a considerable period for a factory of any size to get back to a considerable production basis. If there is one month's normal production—or two months' present production—surplus in the country, all of it will be required to fill the gap between the present and the time the new crop of finished cars is coming through with the desired regularity.

This year the Chicago show has exceeded its record in several respects. It is always a business show, but this year there has been a spirit of determination in every branch of the industry represented here. Constructive work has been done because everyone came here determined to get business no matter how hard it was necessary to fight for it. There has been a feeling all through the industry that the ice had to be broken on the firing line; that renewed business must begin in the dealers' salesrooms. Even parts manufacturers have openly expressed the idea that it is their duty to see that the proper vigor and fighting spirit is being displayed in the salesrooms of the companies using their products. The parts makers have been brought into closer contact with the actual selling of cars than ever before by the recent practice of cancelling contracts.

The parts makers reason that if the manufacturer is going to cancel orders because sales are slow and his cars are not moving, it is no more than reasonable that he assure himself that the manufacturer is putting forth the proper effort all along the line, particularly in the selection of his dealers and their methods.

The keen interest of the dealers themselves in the future of the industry and of their own business was evidenced in the annual meeting Monday and Tuesday of the National Automobile Dealers Association, at which the relations between the dealers and factories was the principal subject of discussion. Strong feeling regarding cancellation clauses in dealer contracts and arbitrary methods by factories has existed for some time and has been detrimental to business. The N. A. D. A., after discussing the subject, sent a communication to the National Automobile Chamber of Commerce asking that the manufacturers appoint a committee to meet with a committee of the dealers for the purpose of discussing trade practices and eliminating anything detrimental to the development of the industry. Robert J. Schmunk, vice-president and sales manager of Peerless, opened the discussion which was supplemented by a letter from C. W. Nash. Both stated that some of the industry's past practices are detrimental to business and should be corrected.

A point which must not be overlooked is the tremendous effect on general business conditions which will inevitably result from the acceleration of this great industry, which does a business of over two billion dollars a year. In fact, the general resumption in the automobile and parts plants alone will materially affect sales in the industrial territories. It is illuminating to consider the number of persons who are able to buy cars because they are in the business of making cars or parts. Sales in Michigan, Indiana and Ohio are expected to immediately result from the reopening of production.

The activities which are generally on the program for Chicago show week are in full swing. The salon at the Drake Hotel, with fourteen makers showing 43 cars, has been well attended. Despite the fact that the special bodies on these cars and the chassis shown are among the highest priced in this country and Europe, a highly satisfactory volume of business has been done.

Judged from an engineering and manufacturing standpoint, it may be said that no new cars appeared at the Chicago show. The three cars shown which are new to the general public are all assembled products incorporating units with which the industry is familiar. These new cars are the Winther Six put out by the manufacturers of the Winther truck, the Ambassador, which is a product of Shaw of Yellow Taxi fame, and the third is the Sterling Knight, of which the initial product is being exhibited at the salon and for which there are as yet no factory or manufacturing plans. The car is the design of engineer Sterling, formerly of the B. F. Stearns Co.

If the New York show had been moved bodily to the Coliseum in Chicago it would hardly have presented more similarity. In fact a great percentage of the exhibits were shipped directly to the Coliseum and Armory after the New York show. All three of the new cars are at the hotel exhibits. The Ambassador and the Sterling make up part of the salon which is being held at the new Drake Hotel and the Winther is shown at the Sherman. In connection with the salon, six of the leading body manufacturers, Fleetwood, Rubay, Graff, Smith-Springfield, Kimball and Willoughby are exhibiting their products on foreign chassis or on American chassis of the higher price class.

The new Ambassador is a high-priced product incorporating the Weidely twelve-cylinder overhead valve engine. This unit, which has been on the market for some time and which was formerly used by an Indianapolis car manufacturer, has its cylinders cast in blocks of three. It has a bore and stroke of 2⅞ by 5 in. and develops 82 b.hp. at 2700 r.p.m. The unit powerplant construction is used with a Brown-Lipe multiple-disk clutch and an aluminum gearset of the same make fitted with Timken roller bearings.

The axles are Timken, the rear being of the floating type. The drive to the rear axle is through a hollow propeller shaft and two Thermoid universals. Other

parts include a split-nut steering gear, 8-in. channel frame with four cross members and a rear cross plate, and chrome vanadium semi-elliptic springs. The rear springs are 58½ in. long. The wheelbase is 136 in. The electrical equipment includes Westinghouse starting and lighting motors and the new Philbrin ignition system. The car is fitted with 32 by 4½-in. tires on the roadster and four-passenger cars and with 33 by 5-in. tires on the closed models.

The Winther Six is manufactured in the plant which is also devoted to the manufacture of Winther trucks. This car is being put out by the Winther Motor Sales Corp. and is also an assembled job. It utilizes the Herschell-Spillman engine, with a bore and stroke of 3¼ by 5 in. This unit is credited with 60 hp. at 2200 r.p.m. It is a block-cast design and in the Winther car is utilized in unit powerplant form, including Warner clutch and gearset. The gear ratios in the box are 1.64 to 1 in second, 3.24 to 1 in low, and 4.05 to 1 in reverse. The reduction in the rear axle is 4 5/11 to 1.

The rear axle is a three-quarter floating, ball and roller bearing type, with spiral bevel gears. The rear wheels are carried on ball bearings and the differential on taper rollers. The propeller shaft is hollow with metal universals at each end. The drive is Hotchkiss. A feature of the universals is the magazine oiling system which operates through centrifugal force, necessitating a filling but once in 5000 miles, according to the claims of the manufacturers.

Westinghouse electrical equipment is used for starting, lighting and ignition. The generator is mounted on the right side of the engine and the drive is taken through the waterpump shaft. The battery is a Willard of 127 amp.-hr. capacity. The battery mounting, which is under the front seat, is swung from the chassis and is independent of the body. Gasoline feed is by Stewart vacuum system to a Stromberg carbureter. The car is fitted with Velvet recoil snubbers as stock equipment. Other equipment includes a motor-driven tire pump, cowl ventilator, Motometer and a Klaxon horn. The car is being put out with a touring body and the latter is equipped with a De Luxe winter top as special or extra equipment when so ordered. The wheelbase is 120 in. and regular equipment includes 33 by 4-in. cord tires.

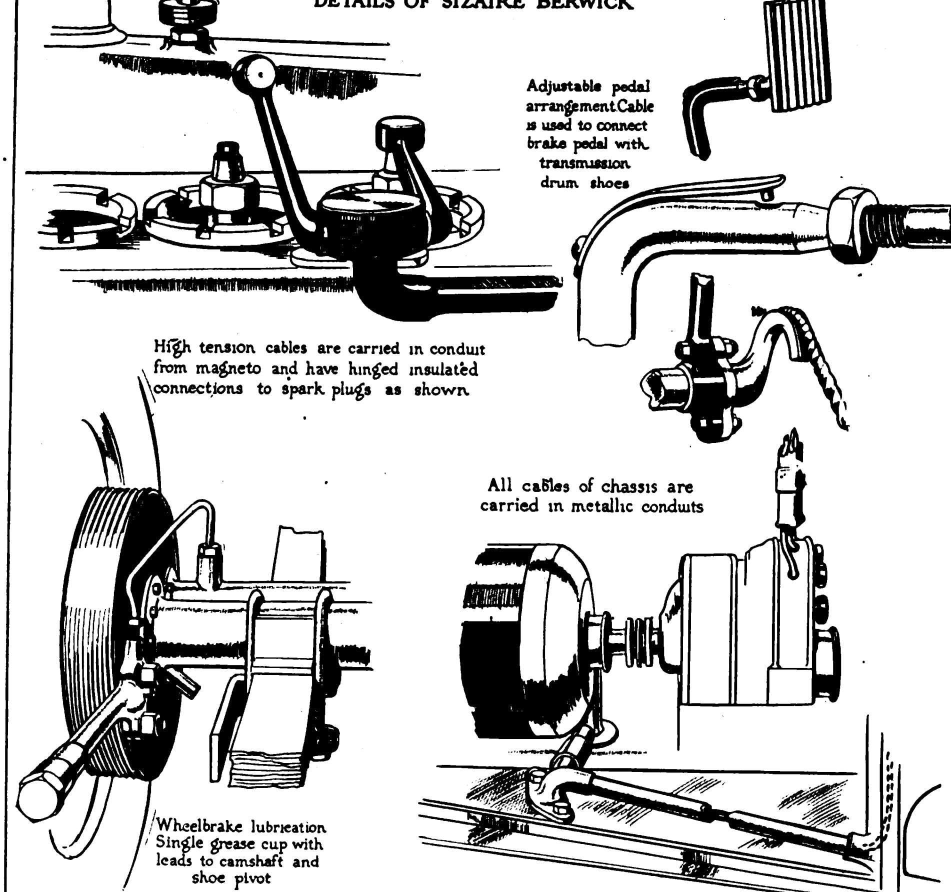
Detail Refinements Characterize Sizaire Berwick Chassis

By M. W. Bourdon

THE Sizaire Berwick chassis designed by French brains and made in London differs but little from the chassis shown at Olympia in 1919. The plant in which this car is built is one of the most up-to-date in equipment in England and planned for production as well as any and better than most.

The latest chassis displays the same elaborate attention to details which characterized previous models. All wiring is inclosed in metal conduits, and even hinged insulated connections for the spark plugs are provided. The fittings on the instrument board have translucent dials with an electric light behind them. The cast aluminum dashboard is surmounted by a horizontal vacuum feed tank of 1.8 gal. capacity and other similar refinements are provided.

DETAILS OF SIZAIRE BERWICK



The four-cylinder 3¾ x 6 5/16 in. L head engine now has a pump for water circulation driven from the camshaft by a transverse shaft and located at the center of the crankcase on the right, the camshaft being on the left. The clutch is of the disk type and the amidships gearset with four speeds and right-hand control is suspended at three points from brackets attached to a subframe. From the ribbed drum of the internal expanding transmission brake the drive passes through an open tubular propeller shaft with ball-bearing star joints at each end to the spiral bevel final drive with a ratio of 4 to 1. A feature of the universal joints is that they are automatically lubricated, one from the gearset and the other from the rear axle casing.

The back axle is of the semi-floating type with self-aligning ball bearings on the ends of the tapered extensions of the axle center. The rear semi-elliptic springs take torque and drive and are arranged immediately under the side frame members. Internal expanding brakes are used on the rear wheels, which are wire spoked.

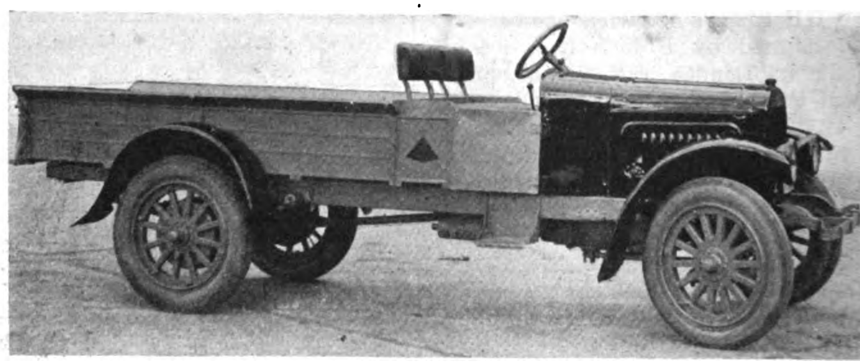
Three Point Chassis Mounting Feature of New Speed Truck

Transverse front spring with pivot joint connection to frame renders truck especially suitable for farm use or on rough roads. Midwest engine with two-bearing crankshaft and full electrical equipment is rigidly mounted on two forward points but has flexible connection with frame at rear supports. Rigid frame designed to prevent weaving of bodies.

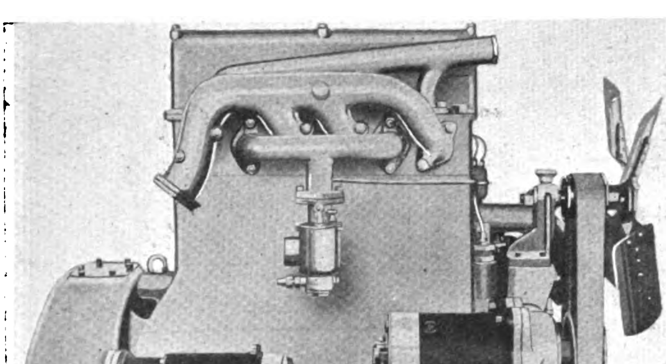
THE outstanding feature of the ¾-1 ton speed truck of the Service Motor Truck Co. is the three point mounting of the chassis. The truck is evidently intended for farm use to a certain extent. In such service the trucks often have to leave the highway, they must be built so as to be able to readily accommodate themselves to very uneven ground or be subjected to very severe strain. In the Service truck the plan of arranging the front spring transversely, generally followed in farm tractor practice, is adopted. There is a pivot joint between the spring and the frame at the middle, and the axle is steadied by radius rods attached by a ball joint beneath the transmission.

Flexibility is not confined to the running gear, but is aimed at also in the support of the unit powerplant. The latter comprises a Midwest four-cylinder 3⅝ x 5 in. engine, developing 40 hp. at 1800 r.p.m., a Brown-Lipe dry plate clutch and transmission. Power is transmitted through a metal universal joint, a tubular propeller shaft, and a fabric universal joint to a model 1000 Eaton spiral bevel gear drive axle.

The engine is one of the new products of the Midwest Engine Co., and has many of the same features of construction employed in their larger type of engine. The four cylinders are cast in a block and are integral with the upper half of the crankcase. The oil pan is of pressed steel. The removable cylinder head permits machining of the entire combustion chamber and enables clean coring of the water passages. Alloy steel valves, 1 17/32 in. at the throat, are used. The valve lift is 11/32 in. The rocker-arm construction is identical with that of the larger type Midwest engine. The push rods are surrounded by breather tubes, which insures oil vapor lubrication of the rocker-arms. A tappet platform is bolted to the upper half of the crankcase.



Service ¾-1 ton speed truck

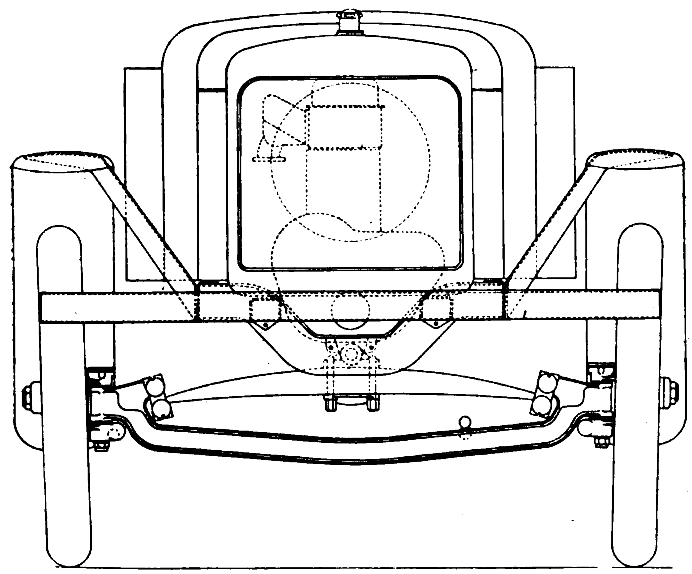


Midwest 3½ x 5 in. truck engine with full electric equipment

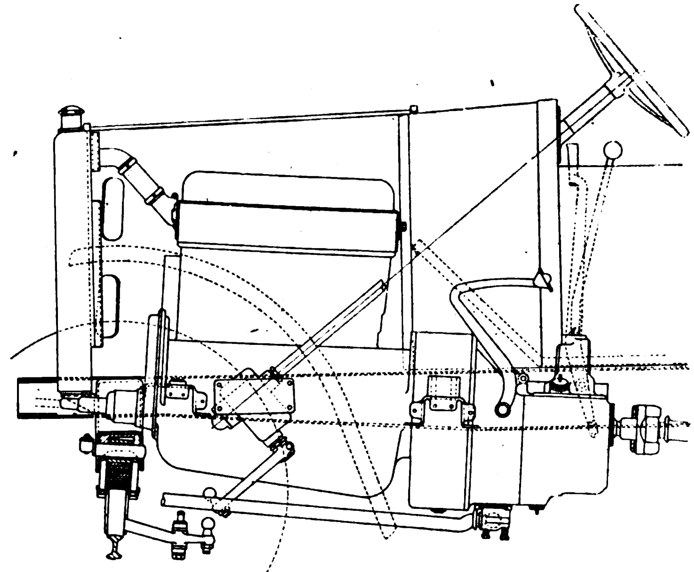
Cast iron pistons 4½ in. long are used. They are provided with grooves to accommodate three rings above the piston bosses. The piston pin bearing, which is 1⅛ in. wide and 15/16 in. long, is located in the piston. Connecting rods are of the usual I section, 10½ in. long, and are made of S.A.E. No. 1040 steel. These rods are belled out at the crankshaft end and the flange is carried to the center of the bearing. This construction is employed to keep the bearing round and prevent distortion when the cap is drawn up tight. Connecting rod bearings measure 2½ x 2½ in. and the bearing cap is held on by two ½ in. nickel steel bolts.

This model differs from the larger Midwest engines in that it has a two-bearing, counter-balanced crankshaft. Counter-weights are bolted to the shaft with nickel steel bolts, riveted over, and dowelled bushings where the counter-weights come in contact with the shaft. The front crankshaft bearing is 2½ by 2¾ in. and the rear crankshaft bearing, 2½ x 3 5/16 in.

The same force feed system of lubrication is employed on this model as on the larger type. The geared oil pump is of the self-priming type and has a capacity of 1 7/10 gal. per min. at 1000 r.p.m. Oil is drawn from the lower



Front elevation of chassis



Elevation of forward part of chassis, showing trunnion support of frame and location of radius rods

pan, which has a capacity of 2¼ gal. A plunger controlled by the vacuum of the manifold regulates the oil flow in relation to the actual load on the engine. This allows ample lubrication for full load and prevents excess oiling at light or medium loads.

Cooling is effected by a radiator with a continuous fin and tube type core. The pressed steel radiator shell is mounted on leather pads to absorb vibration. Water is circulated by a pump having a capacity of 18 gal. per min. at 1000 r.p.m. and the air is drawn through the radiator by an 18 in. fan, driven by a 2 in. flat belt. The Remy system of battery ignition is employed, together with a Remy generator and starting motor and an Exide truck battery. A Stromberg carbureter with hot air stove attachment and choker controlled from the instrument board is used. Gasoline is carried in a 12 gal. tank in the cowl.

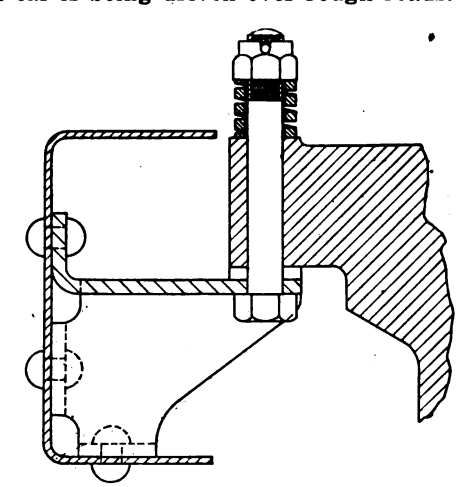
Power is transmitted through a single drive plate clutch and a Brown-Lipe Model 30 transmission. The clutch housing is of cast iron. The method of adjusting this clutch is somewhat different from that employed on other Brown-Lipe clutches. A nut of malleable iron, which moves mild steel plugs in and out, is provided. These plugs change the relative position of the toggle levers, which are hardened forgings, and they, in turn, regulate the pressure on the pressure plate. The pressure plate is cast iron and the driven disks are pressed steel, ground on both sides. The clutch facings are of moulded Raybestos, 10 x ⅛ in. The clutch shaft is of low carbon, 3½ per cent nickel steel, and of 1½ in. diameter. Whereas radial and thrust bearings are used in most Brown-Lipe clutches, this clutch is provided with a straight thrust bearing. The transmission is provided with speedometer drive at the rear.

A 2½ in. tubular propeller shaft is used, with a Merchant & Evans universal joint at the front and a No. 2206 Goodrich fabric joint at the rear. The latter provides a cushioning member between axle and transmission.

The front axle is of the reverse Elliott type, drop forged of alloy steel, heat treated. This axle is specially designed to accommodate the front cross spring. The axle center is 2½ in. deep, 1⅝ in. wide and has a ⅜ in. web. The front spindles are 1½ in. in diameter and are fitted with taper roller bearings. The rear axle is designed for the Hotchkiss drive but can be equipped with radius rods if desired. Optional gear ratios are 5⅛, 5⅝ and 6 1/7:1.

Cam actuated internal brakes act upon brake drums 15¾ in. in diameter. The width of the brake shoes is 1¾ in. Both brakes are placed inside the frame to avoid interference with skid chains. The lug at the rear of the brake bands is provided with a slot which permits the brake band to center itself when the brakes are applied. This results in more even wear on the band.

The steering gear is of the worm and sector type and is of Service design and manufacture. A small metal stamping covers the joint between knuckle pin and steering head and aids in excluding dirt. Left hand drive and center control are provided, the gear shift and emergency brake levers being mounted on the transmission. The spark and throttle are controlled by levers under the steering wheel and the throttle is also under the control of a foot accelerator. The pedal of the accelerator is so designed as to eliminate continual opening and closing of the throttle when the car is being driven over rough roads.



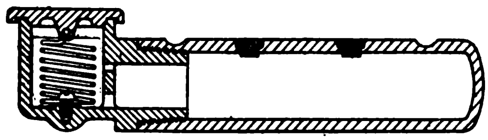
Flexible rear engine support

The frame is made of pressed steel, the channel section being 5⅞ x 3 x ⅛ in. between dash and rear spring front hanger, tapering to 3¾ x 2 in. at the rear end and 3⅞ x 2 in. at the front end. The length of the frame back of the driver's seat is 101.5 in., the width 30¾ in. at the front and 37 3/16 in. at the rear.

The front cross spring is 38 in. long, 2½ in. wide and has nine leaves of a total thickness of 2 21/32 in. The spring eyes are bronze bushed for 1¼ in. shackle bolts. This spring is shackled at both ends of the front axle and is trunnioned at the center. The shackle bolt, which is

drawn from low carbon steel, is screwed to a die cast oil cap with the cover held in place by a spring. Two pieces of felt about 3/8 in. in diameter transfer the oil from the reservoir to the bearing surfaces.

The use of the front cross spring makes it necessary to provide radius rods. One end of the radius rod has a ball joint at the bottom of the transmission, the socket of the ball joint being held in place by four bolts. The front end of the radius rods has a taper fit in the front axle. The use of this type of front spring suspension makes necessary the use of four-point suspension for the engine, but permits the use of a very rigid frame, which is particularly desirable. Four-point suspension always gives rise to the question of how the engine can be bolted down tight. The two bolts holding the rear legs of this engine are bolted down against the tension of heavy coil springs, which allow a certain amount of flexibility and insure keeping the legs tight at all times. It is said that considerable trouble (with bodies in particular) has been caused by the use of a flexible type of frame, and this type of suspension, which permits the use of rigid frame construction, is intended to obviate this trouble. The rear springs are of the conventional type, semi-elliptic, 50 x 2½ in.



Section of shackle bolts and oil reservoir

This truck is regularly equipped with 34 x 4½ in. pneumatic tires in front and 35 x 5 in. in the rear. The standard gear ratio is 5⅝ to 1 and permits of a speed as high as 40 m.p.h. The truck chassis, provided with a cushion but no seat, is to sell for $1,840, f.o.b. at factory. Two standard bodies, one open and one closed, can be purchased, the weights being about 600 lb. for the open body and 700 lb. for the closed.

Winch Attachment for Tractors

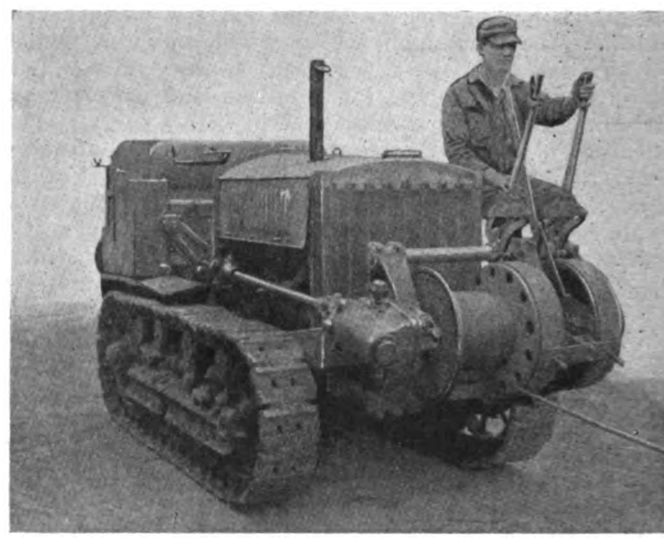
THE range of utility of the 5 ton and 10 ton caterpillar tractor manufactured by the Holt Manufacturing Co. has been increased by providing for use on the tractors a winch attachment as shown in the accompanying cut.

Caterpillar type tractors are extensively used in the logging industry as well as in the oil fields. The winch attachment facilitates skidding logs out of relatively inaccessible places, and is useful in pulling and running back tubing and rods used in oil wells.

The Holt winch is operated independently of the driving mechanism of the tractor. The drive is from the rear of the transmission-case by propeller-shaft and gear-train to internal gear planetary and final bevel gears. A clutch of ample size to permit slipping indefinitely is provided. The standard pulling speed of the 5 ton winch is 108 and 252 ft. per min. on low and high gear respectively, and the corresponding pulls are 10,400 and 4450 lbs. Maximum reverse speed is 583 ft. on low and 1360 ft. on high gear. Other speeds are obtained by slipping the clutch. Two other sets of gear ratios are provided at option.

The winding drum is 8 in. diameter and 13 in. between flanges, and has a capacity of 1300 ft. of ½ in., 850 ft. of ⅝ in., or 590 ft. of ¾ in. cable.

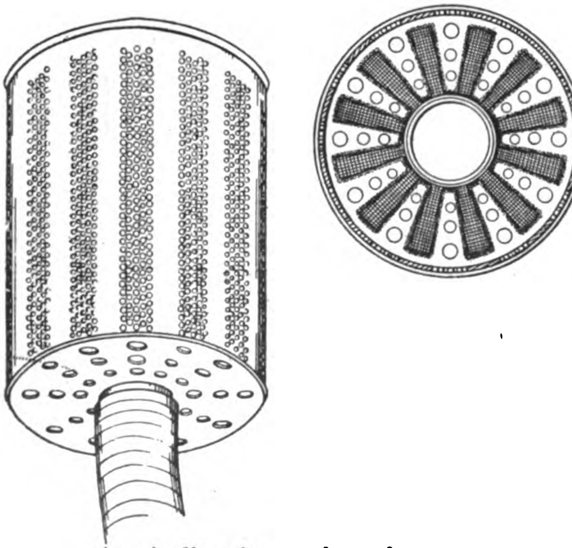
All shafts and gears are nickel or carbon steel, the gears being case hardened. Ball or roller bearings are used throughout and the gears and moving parts are enclosed.



Winch attachment applied to Holt tractor

A Self-Cleaning Air Filter

AN air cleaner in which felt is used as a filtering medium has recently been placed on the market by the Staynew Filter Co. As will be seen from the accompanying cut the device consists of a cylindrical, perforated shell, into which is fitted an elongated spider formed of wire screen and covered with felt. The central portion of the spider communicates with a central tube, through which the clean air entering the carbureter flows. The felt-covered surface spider is said to have an area of over 500 sq. in. The area of the inlet holes being large, the entering velocity of the air is low and consequently the larger particles of dust are allowed to settle out before the air passes through the felt. It is claimed that the air entering the cleaner does not strike directly upon the filtering material and that the dust which collects on the surface of the felt is shaken off by the vibration of the vehicle on which the cleaner is used. The dust shaken loose drops out of the shell through holes in the base.



An air filter for trucks and tractors

Instrument for Measuring Engine Clearance Volumes

Makes use of principle which provides that a simultaneous decrease of known amount in two volumes will produce the same pressure change only when both volumes are equal and the leakage is the same.

By S. W. Sparrow*

A FEW years ago, when the gasoline engine with vertical cylinders was the well-nigh universal type, a description of apparatus to measure clearance volume would have aroused little interest. In the highest part of such cylinders there was usually located either a valve or a spark plug through the opening for which liquid could be poured. The volume of liquid required to fill completely the combustion space with the piston at the upper dead center served as the clearance measurement. To be sure, it was a rather messy procedure requiring considerable time to remove the liquid when check readings were desired, but otherwise was fairly satisfactory. With the advent of the V-type engine, the problem ceased to be simple. Frequently it was almost impossible to make this measurement with the engine mounted for test, as all openings were then below the highest point in the cylinder.

In the summer of 1919, Major Norman of the English Royal Aircraft Establishment at Farnborough suggested making this measurement by a process which consisted essentially of simultaneously changing both a known and an unknown volume of gas by a known amount and then calculating the magnitude of the unknown from the resulting difference in pressure between the two. To Dr. Dickinson, who was in Europe studying aviation development, the idea made instant appeal, and on his return to the Bureau of Standards he started the construction of an instrument based on this principle.

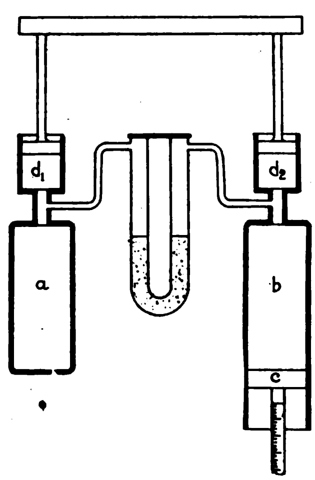


Fig. 1—Diagram illustrating principle of apparatus

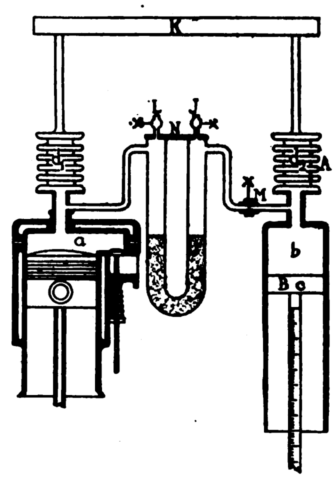

Fig. 2—Diagram of actual instrument illustrated in the photograph

The principle of the apparatus is shown in Fig. 1. If the volumes *a* and *b* are both decreased the same amount by the movement of the pistons, there will be a pressure increase in each cylinder, the greater increase occurring in the smaller volume. The pressure difference will be indicated by the difference in liquid level in the U tube connecting the two cylinders. In practice, volume *a*, the clearance volume, is always unknown, while in the other, volume *b*, can be altered by moving piston *c* in or out of the measuring cylinder and its magnitude read from the scale on the piston stem. This calibrated volume is changed until the movement of the two companion pistons produces the same pressure increase in both cylinders as indicated by the liquid in the U tube remaining level. Both volumes are then equal. The above statements hold true only if both cylinders are airtight or if both leak at the same rate. Since the engine cylinder is never strictly tight, an adjustable opening is provided to permit an equal rate of leakage from the comparison cylinder. For clearness, the simultaneous volume changes are described as taking place in the clearance and measuring volumes, whereas actually there are auxiliary volumes d_1 and d_2, connected with these in which the actual change is made, so that it is (clearance volume + auxiliary volume d_1) and (measuring volume + auxiliary volume d_2) that are changed. The addition of these auxiliary volumes simplifies the apparatus for making the volume changes, and inasmuch as both are equal, does not alter the relations described above.

The actual instrument is shown in diagram in Fig. 2, in section in Fig. 3, and in the photograph, Fig. 4. For producing the changes in volumes, the pistons, shown in the diagram, have been replaced by the cylindrical copper bellows, *A*. Changes in the comparison volume are produced by turning hand wheel *C*, the motion being transmitted to the piston *B* through a gear and rack. A vernier and graduated scale on the piston stem permit the direct reading of volumes up to 48 cubic inches in steps of one-tenth of a cubic inch. Should it ever be necessary to measure larger volumes, an auxiliary cylinder can be connected to Tee *D*, now closed by a pipe plug. The measurement would then be made as before, except that to the reading on the piston stem should be added the volume of the auxiliary cylinder. Tank *E* is a check volume of 7 cu. in., used only for calibration purposes. When the tubing is renewed, fitting *F* is screwed into the tank, screw *G* loosened, and vernier *H* adjusted to read exactly 7.

Measuring clearance volumes consists of three distinct steps:

1. Measuring the rate of leakage from the engine cylinder.
2. Making the rate of leakage from the comparison volume equal to that from the engine cylinder.

*Automotive Power Plants Section, Bureau of Standards. Condensed from N. A. C. A. Technical Note No. 27.

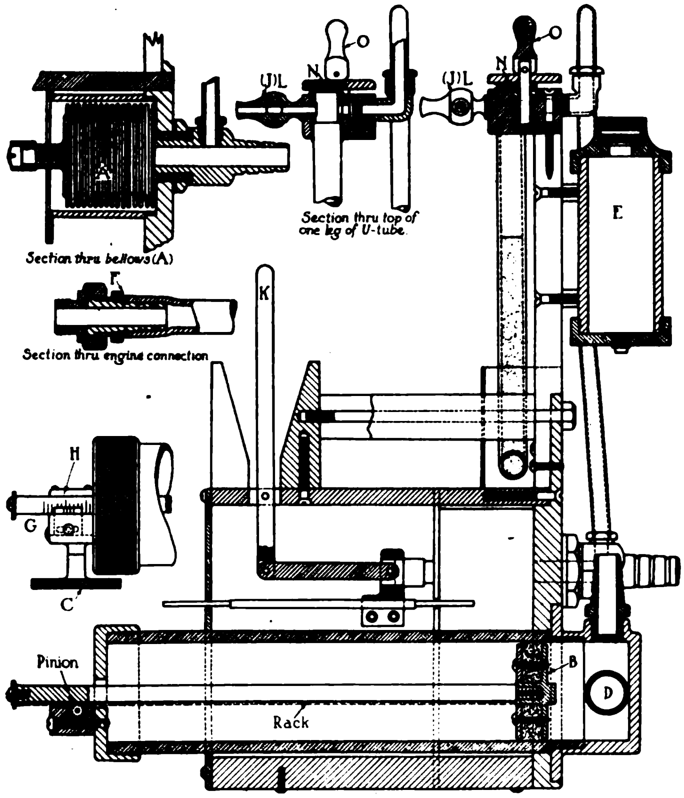

Fig. 3—Sectional view of instrument, showing details of construction

3. Equalizing the comparison volume with the clearance volume.

In measuring the rate of leakage from the engine cylinder, after having latched cover plate *N*, needle valve *J* is opened, leaving the right side of the U tube open to the atmosphere. Lever *K* is then pulled back until a considerable pressure difference is produced. The leakage rate is estimated by noting the approximate time required for the pressure to decrease a definite amount. Valve *L* is next opened and *J* closed, one side of the U tube now being open to the atmosphere and the other connected to the comparison volume. Valve *M* is then adjusted until the leakage rate is approximately the same as that from the engine cylinder.

In equalizing the volumes, valves *J* and *L* are both closed, the left leg of the U tube then being connected to the engine cylinder and the right leg to the measuring cylinder. When changing the volumes by means of lever *K*, it is most convenient to watch but one leg of the tube. If the left leg be the one chosen and the initial movement of the liquid is downward, it indicates the pressure in the engine cylinder to be the greater and its volume to be the smaller. After relieving the pressure on both sides by raising cover plate *N*, the volume in the measuring cylinder should be decreased. The cover plate is again lowered and secured tightly with latch O and the process repeated. The correct volume is that with which there is no change in liquid level noted at the first application of the pressure.

It will frequently be found that with the volumes well equalized, after the pressure has been maintained for a second or two, the deflection of the liquid in the U tube will increase, showing that the leakage rates have not been perfectly balanced. A few trials will readily convince the operator that it is the initial movement that should be considered in adjusting the comparison volume, and that extreme care in balancing leakage is unnecessary. The explanation will be evident from a consideration of the effect of a difference as large as 10 per cent in the leakage rate from the two volumes. For this purpose, let the rate be assumed as 0.03 cu. in. per second, a rather high value for the small pressure increase produced with this instrument. With the above assumption, a measurement taken at the end of one second will be in error by the difference in the amounts that have leaked from the two volumes, namely, 0.03—0.9 (0.03) = 0.003 cu. in. The sensitivity of the instrument, however, is about 1 per cent, a difference between the comparison volume and the measured volume of this amount being required to produce a readable deflection on the manometer. The 0.003 cu. in. error will therefore be too small to be noticed in measuring volumes of the magnitude of engine clearance spaces. The initial manometer deflection observed can therefore be attributed entirely to the difference in the magnitude of the two volumes.

In using this apparatus, care must be taken to prevent temperature changes in either volume, as a change of 3 deg. C. will change the deflection a noticeable amount, and hence vitiate the result. Obviously, such measurements should never be attempted immediately after operating the engine, before it has cooled to normal temperature.

To attempt precise measurements of a clearance volume without first carefully setting the piston at dead center would be utter folly. Markings on flywheel or propeller hub make this a matter of comparative ease in the majority of cases. In the absence of such markings, the clearance measuring apparatus may be connected as was done for measuring leakage with valve *J* open and *L* closed. This merely enables the U tube on the instrument to be used to measure the difference between the pressure in the cylinder and the atmosphere. Moving the piston toward upper dead center produces pressure; moving it away, suction. In the Liberty "12" one degree motion of the crank from dead center can be detected with this instrument.

THE engineer of a large automotive engine manufacturer states that his company is concentrating all its efforts in fuel study on improving vaporization by applying the hot-spot principle, believing it to be the most logical method adaptable to present-day types of engines.

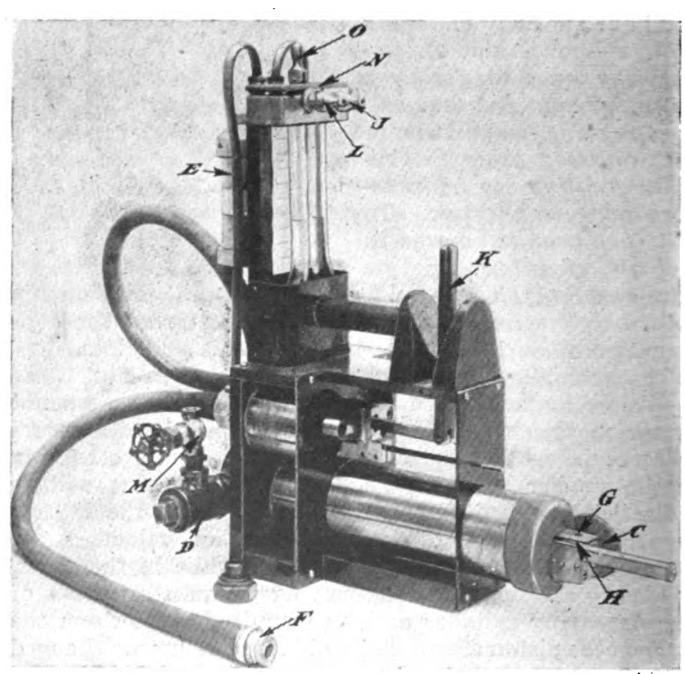

Fig. 4—Instrument developed by the Bureau of Standards for measuring clearance volumes

Two Recent French Pursuit and Racing Planes

Borel machines are both biplanes and use 300 hp. Hispano-Suiza engines. The pursuit machine has good streamline nose, clear vision, and carries radiators under fuselage. Fuel tanks can be instantly released in case of fire. Racing plane first seen in Gordon-Bennett trials.

By John Jay Ide

THE Société Anonyme des Aéroplanes Borel has recently produced a pursuit type airplane which can be used either as a one or a two-seater. It is noteworthy for the good streamline form of the nose, a relatively short fuselage, a stabilizer adjustable on the ground, long narrow ailerons on the lower wing only and wings staggered forward.

There are two bays in the biplane wing structure cross-braced by streamline wire. The lower plane has no dihedral but the upper plane has a dihedral of 2 deg. The angle of incidence of both planes is 2° 30′. The forward stagger is 15 in. The leading edges of the wings are covered with three-ply and the trailing edges are composed of steel wires. Both interplane struts and wing spars are of spruce. The factor of safety of the cellule is 7 for normal loading and 3.5 for top loading.

The balanced ailerons are operated by duralumin tubes, the control wires of which are doubled. The comfort of the pilot was considered in making adjustable not only the height of the seat but also the position of the rudder bar with reference to the seat. A stream of hot water taken from the carbureter heater runs through the rudder bar.

The upper plane is at the height of the pilot's eyes and the straight line from the pilot's eyes to the leading edge of the lower plane is at an angle of 18 deg. with the vertical. The vision straight forward is excellent due to the absence of a nose radiator. Cut out portions of the lower wing permit the pilot to see vertically downward. Cooling is by two Lamblin radiators placed under the fuselage. The latter is designed for a factor of safety of 5.5. The longerons are of ash and spruce connected by spruce struts and cross braced with piano wire.

The landing gear struts are of reinforced streamline tubing; the axles are also streamlined. A pivoted ash skid is attached to the stern of the fuselage.

The 300 hp. Hispano-Suiza engine rests on walnut bearers with leather between the bearers and the engine. The two bearers are held in place by metal braces. There are large inspection doors for the carbureter, magnetos, Odier self-starter and plugs.

The two tanks which can be released instantly in case of fire hold sufficient fuel for 2½ hr. flight at full speed at ground level. There is a gravity tank in the upper wing.

The radiators installed under the fuselage are quickly demountable. A filter is placed in the water circulation system. The gravity water tank is in the leading edge of the cabane joining the fuselage and the upper wing.

There are two Vickers machine guns with 1600 cartridges firing forward and two Lewis guns aft, mounted on a ring. The installation of a gun firing downward has been provided for, it being necessary merely to remove a three-ply cover. When the aeroplane is used as a single seater the ring mount is turned and clamped so that the two Lewis guns fire over the upper plane and propeller parallel to the longitudinal axis of the machine.

Provision has been made for two cameras behind the pilot's seat. Parachutes are placed in a case behind the gunner.

The service ceiling is 25.900 ft. and the absolute ceiling 27,100 ft.

Borel pursuit airplane (300-hp. Hispano-Suiza engine) can be used either as single or two seater

The new Borel racing airplane made its first appearance at the French elimination races for the Gordon Bennett Cup last September. Although possessed of very great speed it did not qualify as it was overturned and somewhat damaged in making a landing.

The biplane cellule is noteworthy for the small chord (36 in.) of the planes. The supporting area is increased by a small plane covering the axle of the landing gear. The single strut on each side of the fuselage is forked.

Streamline wiring is used, the attachments at the lower ends of the wires being hidden in the wing.

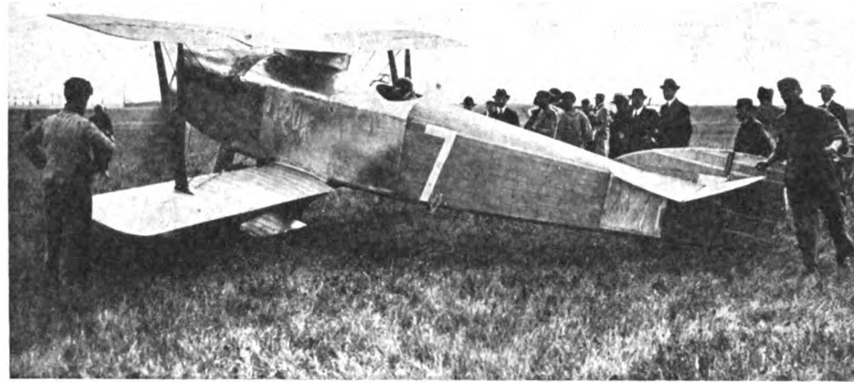
There are ailerons on the upper wing only. Their area is very great relative to

the area of the wing. The fin is of very small size but the rudder is quite large (16 x 32 in.).

The wing area is 140 sq. ft. and the total weight 1936 lbs. The load per sq. ft. is 13.8 lbs. and per hp. 6.4 lbs.

A 300-hp. Hispano-Suiza engine is used cooled by two Lamblin radiators.

The general specifications of the Borel pursuit machine are as follows:



Borel racing airplane (300-hp. Hispano-Suiza engine) used in Gordon Bennett cup elimination race

Span	37.4 ft.
Length	23.3 ft.
Height	8.7 ft.
Chord	5.2 ft.
Wing area	355 sq. ft.
Area of elevator	16.5 sq. ft.
Area of stabilizer	18.8 sq. ft.
Area of rudder	9.7 sq. ft.
Area of fin	5.4 sq. ft.
Weight, empty	1798 lbs.
Useful load (2 seater)	1095 lbs.
Total weight	2893 lbs.
Load per sq. ft.	8.1 lbs.
Load per hp.	9.6 lbs.
Engine	300 hp. Hispano-Suiza

The official performances as a two-seater are:

Feet	Time of Climb	Speed (m.p.h.)
3,280	2 min. 47 sec.	....
6,560	6 min. 0 sec.	143.6
9,840	9 min. 34 sec.	139.8
13,220	13 min. 49 sec.	134.9
16,440	19 min. 31 sec.	128.6
19,680	26 min. 53 sec.	120.6
21,320	33 min. 33 sec.	115.6

The De Pischoff "Avionette"

By John Jay Ide

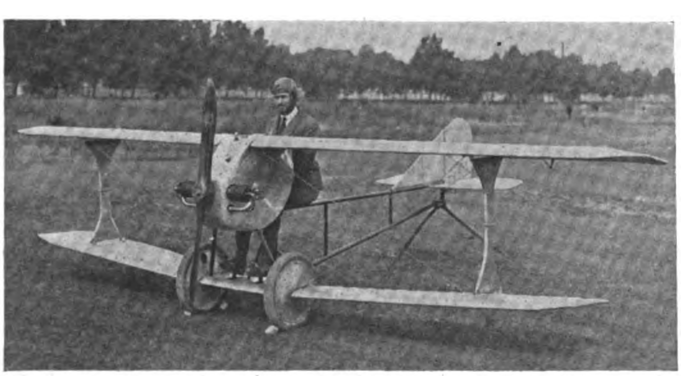
THE De Pischoff "Avionette" is the smallest serious flying machine in France, if not in the world. To prove that it is not a mere toy one has only to point to its performances at the recent Buc Aviation Meet, where among other achievements it climbed to a height of over 2500 ft.

The "Avionette" is a biplane with tail booms and wing structure entirely of metal. The axle of the landing gear is mounted on the front spar of the lower wing, which is only 8 in. from the ground. The interplane struts are of the I type and the fuselage is replaced by a couple of booms carrying the customary tail surfaces. The ailerons are on the upper wing only.

The engine is a 16-hp. two-cylinder horizontally opposed Clerget-Blin. Immediately behind it sits the pilot, of whose anatomy it must be admitted a considerable portion is exposed.

By folding the wings and hinging the tail the dimensions of the machine can be considerably reduced for storage purposes.

The characteristics of the "Avionette" are:



The De Pischoff Avionette

Span	17 ft.
Length	11.5 ft.
Height	4.2 ft.
Wheel track	2.6 ft.
Wing area	81 sq. ft.
Weight, empty	225 lb.
Useful load	176 lb.
Total weight	401 lb.
Speed	59 m.p.h.
Duration	2 hr.
Getting-off run	130-160 ft.
Landing run	65-80 ft.
Factor of safety	5

To Assemble American Parts in Spain

A COMPANY called the Sociedad Española de Automóviles Landa has been organized in Madrid, and has put on the market a four-cylinder car, which is considered to embody all the features necessary to capture the Spanish market. Spain does not at present possess the elements indispensable for the practical construction of cars in all stages, and the Landa company does not actually manufacture the constituent parts of its cars in Spain, but has devoted its whole energy and capital to the organization of a model finishing and assembling establishment.

The Landa chassis are built in Spain with American material, but they are claimed to unite all the good qualities of the most modern type of car. The motor has 3⅞ x 5-in. cylinders. It is said only to consume 12 litres of fuel per 100 kiloms. (5.08 gal. per 100 miles), and to give the car a speed approaching 100 kiloms. per hour. The cars are fitted with the Zenith carbureters and the Westinghouse electrical equipment. A number of chassis are now being built by the company, while the materials for 200 more are on the way, and it is hoped ultimately to turn out 1000 cars yearly.

Researches on Alcohol as a Fuel for Internal Combustion Engines

The object of investigator was to secure basic data on the vapor pressure, ignition temperature, movement of flame through explosive mixtures and the detonation of the vapor of alcohol, gasoline, benzol and various mixtures of two of these fuels. The results are worthy of careful study by those interested in combustion and related phenomena.

By Harold B. Dixon*

THE object of these researches was to obtain data for comparing alcohol with gasoline and other hydrocarbons as a fuel for motor and other small engines, and to determine how far the properties of alcohol are modified by admixture with other volatile liquids. I undertook to make experiments on the burning of alcohol and other vapors on the same lines that had been followed with permanent gases—especially on the ignition of the mixtures and on the movements of the flame in explosions. The work is by no means finished, and I propose to continue and present a more complete report later on.

One further word of introduction must be said. It has been argued—and probably most people agree with the reasons urged—(1) that if the increasing use of motor engines is to be maintained, some fuel must be found to reinforce the world's supply of gasoline; and (2) that of the possible fuels "in sight" which have the desired physical properties, ethyl alcohol alone seems capable of being produced in quantity sufficient to meet the demands of the future. In assenting to these conclusions, there is no question of sounding any alarmist note against the use and efficiency of gasoline, which the world will continue to demand in increasing quantities. We are merely recognizing the fact that the deposits of mineral oil are limited and cannot be reproduced, while the potential supply of alcohol is only limited by our power to produce fermentable sugar through the sun's energy. There is the question of husbanding the world's resources of gasoline, and if power alcohol will help to that end—as I believe it will—it is our duty and our advantage to give it fair trial.

Germany, with characteristic prescience, began more than twenty years ago to foster the use of alcohol, which (with certain additions) has been her standard motor fuel since 1904.

The Vapor-Pressures of Alcohol and of Alcohol Mixtures

On comparing alcohol with other liquid fuels, we find certain properties which affect its use, such as its small vapor pressure at low temperatures, its high latent heat of vaporization, its attraction for and its miscibility with water. For instance, air bubbling through liquid alcohol does not form an explosive mixture, for the vapor carried by the air is too small; but air bubbled through pentane or hexane, through benzol or through ether in each case forms a combustible mixture with too much vapor in it to explode. Alcohol must be heated to give off enough vapor to form an explosive mixture with air; the other mixtures must be diluted with more air to bring them within the explosion limits. Hence the difficulty with an ordinary gasoline engine starting cold with alcohol. There are several ways of surmounting or avoiding the difficulty. If the engine is designed to burn alcohol—using a long stroke and a high compression—the cylinder may be flooded (either directly or through the throttle valve) with a little liquid alcohol in the form of spray, which is warmed by compressing the air in the cylinder. Crossley Bros. are running one of their 4¼-in. x 6-in. 5 hp. single-cylinder engines arranged to give a compression ratio of rather over 8 to 1. With either method of flooding there is no difficulty in starting cold with ordinary industrial alcohol. Running at full load and 500 r.p.m., the engine was remarkably silent. The spray from the exhaust, thrown out while the condenser was cool, was found to be slightly acid, though no evil effects of acid could be found on the exhaust or throttle valve, or on the cast iron piston, after a fortnight's running.

Those who wish to avoid the starting difficulty will look to some mixture of alcohol with other liquid which will readily form an explosive gas with air in the cold. As a guide in making such mixtures, the vapor-pressures of pure alcohol, pure pentane, pure hexane and of various mixtures have been determined, with the results shown in the appended table. It is remarkable that, while the vapor-pressures of pentane, hexane, and ether are lowered by admixture with alcohol (as is usual with miscible liquids), the vapor-pressure of the benzol mixture is above that of either of its constituents. When cold air is bubbled through a 20 per cent benzol-80 per cent alcohol mixture the resulting stream of vapor and air is highly explosive. This mixture has been tested in automotive engines, and no difficulty has been found in starting up cold. With the single-cylinder kerosene engine of Crossley Bros. the volume of liquid fuel consumed per b.-hp. was about 3 per cent less with the 20 per cent benzol mixture than with industrial alcohol alone.

*Professor of chemistry in the University of Manchester. This paper was presented before the Imperial Motor Transport Council.

The difference shown by the benzol-alcohol mixture is no doubt due to the small attraction between the two liquids. The addition of water to the mixture diminishes the attraction, and a dilution is soon reached when the liquid separates into two layers, the denser watery liquid below containing less benzol and the lighter liquid above containing more benzol than the original mixture. Also as the temperature falls the solubility of benzol in alcohol diminishes. The higher the percentage of alcohol in the mixture the more water is required to separate the mixture into two liquid layers.

Similar experiments made with alcohol-hexane mixtures showed that the addition of water caused a separation at lower temperatures than with the corresponding alcohol-benzol mixtures. For instance, with equal volumes of alcohol and hexane, it requires the addition of only 7 per cent of water to separate the liquids at 63 deg. Fahr., whereas the same water added to equal volumes of alcohol and benzol required the whole to be cooled below the freezing point (29 deg Fahr.) before producing separation. For these reasons I have mainly worked with alcohol mixtures containing between 20 and 30 per cent by volume of benzol.

Owing to the heat of evaporation of liquid alcohol being greater than that of gasoline or benzol it is important to warm the intake when using alcohol mixtures. This can be conveniently done by passing all or a part of the exhaust gases round the intake.

The Ignition Temperatures of Alcohol and Other Vapors

Two methods were used for the determination of the ignition temperature of alcohol vapor, and in each case comparison experiments were made with other vapors. Both methods had previously been used for determining the ignition temperatures of permanent gases, and the chief alterations required in the apparatus were means of keeping the stored mixtures, the connecting tubes, and the ignition vessel itself above the condensation point of the vapors, and the substitution by glass, silica, or metal joints of all rubber connections which would have been acted on by the vapors.

Ignition by Heating at Atmospheric Pressure

In the first method, the vapor and the air or oxygen were heated separately by passing them upward through two concentric tubes fitted into a long electric furnace, the temperature of which could be slowly raised and accurately measured. The vapor passing up the narrow inner tube issued at a jet with a sufficient stream to carry the combustible gas rapidly away from the solid silica surrounding the orifice, but not so quickly as to cause the resultant mixture of combustible vapor, containing oxygen or air, to come into contact with the heated wall of the large outer tube before the flame appeared.

The catalytic effect of a heated solid on the ignition of the permanent gases had been already noticed. All combustible gases and vapors when heated with oxygen undergo a "pre-flame combustion," which at the ignition point becomes rapid enough to heat up the gases automatically until the flame appears. Solids affect this pre-flame combustion in two ways: They increase the rate of combination, thereby generally lowering the ignition temperature, but when the flow of combustible gas is very slow the solid may start the pre-flame combustion, but, by conducting away the heat, may prevent the automatic heating-up—so that no flame appears though the orifice of the tube is visibly red-hot. It was necessary to determine by experiment when the rate of flow through the jet and when variations in the diameter of the outer tube ceased to affect the ignition temperatures.

In the case of the vapors now experimented with, the pre-flame combustion is much more marked than with such gases as hydrogen and cyanogen. All the vapors underwent pre-flame combustion as they mixed with the oxygen and passed along the wall of the outer tube, so that the gases would often burst into flame near the upper end of the furnace, and fire back some seconds after the vapor had issued from the jet. This contact action with the wall was particularly noticeable with ether. To overcome this difficulty, two methods were tried: (1) by increasing the air-stream to render the mixture non-inflammable (by dilution) before it reached the wall; (2) by making the flow of vapor from the jet intermittent and timing the inflammation. A combination of these methods was finally adopted; a wider outer tube was used, to increase the relative quantity of air, and the flow of vapor could be started at any moment. When the vapor ignited within a half-second of its issue from the orifice, the temperature of the tube was taken as the ignition temperature.

The ignition temperatures of alcohol vapor coming into contact with oxygen or air heated to the same temperature were fairly definite; those of pentane vapor moderately so. It is noticeable that pentane ignited at nearly the same temperature, whether the vapor came into contact with pure oxygen or air, whereas alcohol ignited at lower temperatures in oxygen. Ether presented a quite abnormal property; when all contact with solids was avoided ether fired below 240 deg. C. (464 deg. Fahr.) in oxygen, but had to be heated to nearly 580 deg. C. (1076 deg. Fahr.) before it would inflame immediately in air. When ether vapor and air are allowed to flow along a tube and are in contact with the heated walls, the mixture gradually heats up, and the ignition temperature, as measured by the temperature of the tube, is quite indefinite.

Ignition Temperature of Vapors Heated Prior to Admixture with Air or Oxygen Heated to Same Temperature

	With Oxygen		With Air	
	Cent.	Fahr.	Cent.	Fahr.
Alcohol	510 to 515	950 to 959	595 to 600	1103 to 1112
Pentane	550	1022	560 to 570	1040 to 1058
Ether	235 to 240	455 to 464	560 to 580	1040 to 1076

The second method of determining the ignition temperatures of alcohol and other vapors was to compress mixtures of the vapor with air or oxygen in a steel cylinder by means of a falling weight driving in an air-tight piston. This method had been carried out successfully with many of the permanent gases, and can be used for the vapors of volatile liquids, providing the reservoir containing the mixtures and the cylinder itself are maintained at a sufficiently high temperature. In most of the experiments the cylinder was kept at 50 deg. C. (122 deg. Fahr.) by a water jacket, in which the hot water was well stirred. In some experiments a temperature of 140 to 158 deg. Fahr. was used, and in a few 212 deg. Fahr.

The rise of temperature produced in the mass of the gas by the sudden compression is nearly independent of the wall surface, which, of course, cools by contact the layer of gas next to it, and, so far as it acts, lowers the pressure. There is no evidence that the steel surface promotes combustion by contact action; indeed, since the temperatures of ignition calculated by the adiabatic law were practically constant, whether the cylinder was at 122 deg. Fahr. or over 176 deg. Fahr. at the moment of compression, such action, if any, must be negligible.

A greater difficulty arises in calculating the ignition temperatures from the observed compressions necessary to fire the mixtures, since the recorded measurements of the specific heats of these vapors vary considerably. However, the latest determinations made by Thibaut give values for the ratios of the specific heats which appear probable. We have accordingly taken the round figure 1.05 for the mean ratio of the specific heats for ether between 50 deg. and 350 deg. C. (122 to 662 deg. Fahr.). From the velocity of sound in pentane vapor at 50 deg. C. we have taken the mean ratio between 50 deg.-500 deg. C. (122 and 932 deg. Fahr.) at 1.065.

The temperatures of ignition calculated from the compressions must be regarded as only approximations. What is more important, especially for the engine designer, is the fact that this method gives with a near approach to accuracy the actual volume change necessary to fire the particular mixture by adiabatic compression, starting from any known temperature. The calculated ignition temperatures will probably be varied as our theoretical knowledge of vapors improves; but the compression volumes determined are independent of theory.

The ignition compressions were measured by a system of trial and approximation. For each mixture the compressions were gradually increased until the mixture exploded; in another series the compressions were gradually reduced until the mixture did not explode. Then experiments were made in the neighborhood of these two points, and a mean compression taken between the nearest exploding and non-exploding trial. In some cases the compressions "overlapped" — a non-explosive mixture being fired by a slightly less compression in a second trial. In such cases I have inclined to the lower value as the safer to give. Of all the vapors and mixtures tried, the vapor of pure benzol mixed with air seemed to have the most indefinite ignition temperature. I have given in the appended table the lowest compression limit observed.

The ignition temperatures by adiabatic compression for alcohol with oxygen and with air are what we should expect from the results at atmospheric pressure. At the high pressure the ignition temperatures are lower. With pentane the results show a similar agreement, but with ether the results are discordant. The ignition temperatures in the heated tube at atmospheric pressure were much lower with oxygen, and much higher with air than the temperature found by compression. The latter were very consistent and definite.

The Movements of Flame Through Explosive Mixtures

The mode in which the flame spreads throughout an explosive mixture of gases and the rapidity of chemical combustion taking place in the flame depend not only on the nature of the gas mixture, but on the method of firing. When an explosive mixture is lit by a flame or a hot wire near the open end of a tube the flame travels through the mixture slowly at first, then more quickly and jerkily. Fired near the closed end of a tube, the same gas will propagate a flame with greatly increased velocity. When the gas mixture is fired by a spark the travel of the flame depends on both the intensity and the position of the spark. When the spark is passed close to a surface the flame starts slowly; when the spark is at a short distance from one end the sound wave starting **backward** from the spark, and traveling faster than the flame, reaches the near end, and is reflected back — passing through the flame, and hurrying it up. Similarly if the tube is short the sound wave starting **forward** from the spark may reach the far end of the tube before the flame, and being reflected back passes through the advancing flame—checking its advance, but causing more rapid combination where the sound wave passes. These reflected

waves, due to sound, are more intense than the original flame, and they become more intense by the combustion they promote. It may thus happen that the explosion only becomes brilliant after the flame has completely traversed the mass of combustible gas. In this brilliant flame which can be analyzed photographically on a rapidly moving film, the sound waves can be seen crossing and recrossing the tube from end to end. The flame traversed by these intense waves may be (and usually is) so much more luminous than the original flame that the latter may escape detection altogether. Von Oettingen, a pupil of Bunsen, who first photographed these waves, declared that the explosion wave itself was completely invisible, and one only saw bits of glass and dust detached and heated up by the non-luminous explosion. My photographs have proved that the explosion wave is not set up at once, but that the flame starts slowly, and gradually increases in velocity and intensity, especially when sound waves are reflected through it. At a certain point in its course the explosion wave may be started; this point is marked by several distinct characteristics. The speed of the flame increases. It is no longer varying, but constant, and it continues at a constant velocity as far as the gas mixture extends. As it travels faster than sound in the upburnt gas it can send no pressure wave in front of it. At the moment when the explosion wave is started forward a well marked wave —which I have called the retonation wave—is sent backward through the burning gases and a dark region is left between the two bright waves. When the explosion wave strikes the end of the tube it sends back a reflection wave, which is easily photographed as it passes backward through the heated gas—in many cases undergoing secondary combustion—for example, the burning of carbon monoxide formed in the explosion wave.

If the tube is of such a length that the explosion wave has not been set up by the time the flame reaches the end of the tube, a reflected wave comes back across the flame. This promotes combustion, which may become very intense at the first or second reflection; it does not set up a true detonation, and the flame lasts much longer than if the explosion wave had been started. But the flame may reach the end of the tube at the precise moment when the explosion wave starts. In this case the wave of retonation comes back with the reflection wave superposed on it —with the result that it is scarcely distinguishable from the explosion wave itself. This is the extreme instance where a reflected wave differs wholly in velocity and intensity from the impinging wave. The chemical reactions appear to be as rapidly completed in this wave as in the true explosion wave. It is evident that in the original flame the combustion is slow, and Bunsen's statement that the spread of the flame "is synchronous with complete combustion" is quite erroneous.

The size and shape of the explosion vessel are important elements in determining the nature of the flame, and so is the position of the spark.

Unfortunately the initial flame in alcohol is hard to photograph, and it is especially difficult when the vapor is mixed with air. After many trials we have succeeded in getting photographs on which the initial flames can be traced and a comparison made between alcohol and other vapors under similar conditions, but the images are too faint to make prints or lantern slides from.

A careful comparison of the photographs yields an unexpected result: The alcohol flame **starts faster** than the hexane, pentane, and ether flames, which keep close together, while the benzol flame is left far behind. But though the alcohol flame is quick off the mark it cannot increase the pace as the others do. Hexane catches it in less than seven ten-thousandths of a second, ether and pentane a moment later.

There is a general opinion that if the charge is fired in any part of the combustion chamber of an engine by "spontaneous ignition," that is, by compression before any flame reaches it, this portion of the charge necessarily detonates. Nernst has given his authority to this view. Now, it is possible to photograph on a rapidly moving film, and analyze the flames produced by the rapid compression of gas mixtures. It has been found in all cases of firing by adiabatic compression that the flame starts comparatively gently, and does not set up detonation immediately. Indeed, many gas mixtures, fired by compression, do not set up the explosion wave, but continue to burn quietly while they push out the piston. Such flames, in spite of the rapid compression, are singularly free from the sound waves that are so strongly marked when the gases are fired by a spark. Of course, an explosion wave is more readily set up in a hot compressed gas than in a similar uncompressed gas, but compression does not necessarily set up the explosion wave. In this connection I should like to give a word of warning against any conical pocket or recess in the combustion chamber—for example, in the sparking plug; for it is much easier to produce firing by compression when the gas is driven toward the small end of a cone. If it be found necessary to quicken the initial flame, two sparks might be employed at such a distance apart that the sound waves started from each should cross and intensify the other flame.

The Detonation of Alcohol and Other Vapors

The detonation of a gas mixture, as of a high explosive, is due to the passage of an extremely rapid shock or wave through the substance, the intensity of the shock being continually renewed by the chemical reactions it produces as the shock passes from molecule to molecule. The explosion wave, discovered by Berthelot, and observed almost at the same time independently by Le Chatelier and myself was explained by Berthelot as due to molecular impacts causing a disk of flame to move forward with the mean velocity of the molecules themselves while they still retain all the heat due to the chemical change. The explosion wave is therefore a definite physico-chemical constant depending only on the nature of the burning substance, and calculable when the chemical change and the heat evolved are known. Although certain factors in Berthelot's formula have been shown to be erroneous, his fundamental idea connecting the rate of the flame with the velocity of the reacting molecules has been retained. It is now seen that in the explosion the mass of reacting gas moves bodily forward, comes to rest and swings back again. According to Prof. Jouguet, the explosion wave travels forward with the velocity of sound in the forward moving gas, which is itself moving with nearly the same velocity, and therefore the actual rate of the explosion wave is equal to the sum of these two velocities, or twice that of sound in the burning gas. Fortunately this conclusion is easy to verify with the camera. A sound wave can be dispatched through the burning gases behind the explosion wave, and its movement can be photographed—if it is not too close to the intensely bright explosion wave. Such a sound wave travels nearly as fast as the explosion wave it is following—the difference in rate being due to the gas, in which it is propagated, having already lost a little of its forward velocity.

The close approximation between the measured velocities of the explosion wave and those calculated from M. Jouguet's formula show, I think, that the chemical combination must be very rapid in the wave, whereas in the region of ordinary explosion the flame traverses the vessel, leaving a large percentage of slowly burning gas behind it. In the explosion wave the collisions of molecules are so violent that most of them cause chemical change where

this is possible, and the flame is usually short lived and intense. In ordinary explosions only a small proportion of the molecular collisions are chemically fruitful, and the flame continues to burn long and quietly.

Now, the explosion wave or detonation has the effect of a hammer blow on the walls of the vessel; hence the use of high explosives in which the explosion wave is set up by a detonator. Detonation must be avoided in the internal-combustion engine; hence it is necessary to determine the conditions under which it can be set up in alcohol and other vapors. All the vapors tried will detonate when they are mixed with oxygen and fired in a long tube. When mixed with air under atmospheric pressure alcohol and ether just propagate the explosion wave, while pentane and benzol are just beyond the limit. But though these vapors will not detonate with air under atmospheric pressure, it is evident that an increase in pressure such as is used in an automobile engine would bring them within the range of detonation.

As might have been predicted from previous work on cyanogen, ethylene, and acetylene, it was found that alcohol, ether, pentane, and benzol all gave faster rates of detonation when mixed with oxygen insufficient for complete combustion. This is explained in part by the formation of carbon monoxide, either directly or indirectly, in the wave front, while the formation of carbon dioxide is only possible where the flame is cooler—behind the wave front; and possibly by the separation of free hydrogen. In the explosion of benzol with insufficient oxygen large quantities of finely divided carbon were deposited, some of the molecules probably breaking up by impact in the wave front into free carbon and hydrogen. There appears to be no striking difference between the four fuels in the rates of the explosion wave either when the vapors were fired with pure oxygen or when the explosions were damped down with nitrogen. The ether mixtures gave slightly the fastest rates, alcohol the slowest, under similar conditions.

The accuracy with which the rate of the explosion wave can be measured has suggested its use in determining the temperatures reached in explosions and the specific heats of the gases concerned. The rate has also been used for determining the nature and the order of the chemical changes taking place in explosions—for example, for showing by what steps the carbon in hydrocarbons is burnt.

Conclusion

In the course of these researches it has been made clear that alcohol possesses most of the properties required in a motor-fuel. As compared with gasoline, its lower calorific value is almost compensated for by the greater compression at which it can be used—and this property (of high ignition temperature under compression) is hardly altered by admixture with 20 per cent of benzol, or of gasoline itself. Such a mixture readily starts in the cold, and has been shown to run very smoothly, and without knocking in an engine.

I have not touched on the question of denaturing, but I would urge that the less methyl alcohol employed the better for the liquid as a fuel. By cutting down the wood spirit the strength of the explosion is increased, and it should not be necessary to maintain the present high proportion since the nauseous taste of crude wood spirit is largely due, not to the methyl alcohol itself, but to a small quantity of a less volatile constituent.

I think there would be some advantage if one or two standard alcohol mixtures were authorized, one of which could be used in existing engines with only slight adjustments. Engineers would soon work out the most efficient designs for burning a standard power alcohol.

If alcohol mixtures can be used for ordinary motor transport, saving 70 to 80 per cent of other fuel, by so much will our limited resources of petrol and benzol be husbanded for the special services in which they cannot be replaced.

Civil Aviation in England

DURING the six months between April 1 and Sept. 1 a total of 689,600 machine miles were flown by British civil aviators, a large increase over the mileage of the preceding half-year. The number of passengers carried has also increased, the figure for the period named being 32,345. The number of departures and arrivals to and from England and the Continent has increased from 734 to 2445.

This large development in civil aviation has naturally brought with it many improvements in service and facilities. Landing fields have increased in number and have been improved in quality. Regulations regarding pilots have been revised, and extensive research in regard to power plants has been carried on. Much of this information is of interest to those interested in American aviation and is contained in the recent Half-Yearly Report on the Progress of Civil Aviation, presented by the British Air Ministry.

Interesting investigations have also been carried out to minimize the effects of mist and fog by mechanical dispersal, to secure the illumination of landing grounds, and to produce mechanical apparatus to cause machines to flatten out automatically before touching the ground. Methods have also been investigated for obtaining instruments to indicate accurately to the pilot his position in relation to the airdrome, and his height above the ground.

The Department of Research has been paying special attention to the development of new types of power plant. If these experiments are successful, it will be possible to use a fuel of a higher flash point, thus increasing both safety and cheapness.

Several new designs of aircraft with facilities for making adjustments to the engines during the flight are being made, and a satisfactory engine starter for use on the ground is now available.

The report states that a wireless direction finder apparatus, which had been installed at Croydon, proved to be of great value. It enables aircraft to correct their course in thick weather. The equipment of aircraft with wireless telephones is becoming more common, as it has been found to be of great assistance to navigation.

Names of towns and railway junctions around London are being so marked that they can be seen from the air, and electric landing lights for indicating the direction of landing are being installed at the Croydon Airdrome.

The Air Ministry has given assistance to insurance companies to establish aviation insurance on a sound basis. Lloyds have issued a civil aircraft record, the first publication of its kind in any country.

ACCORDING to the Department of Statistics of India, 1041 motor cars were imported into British India during September, 1920, and of them no fewer than 723 cars were consigned from the United States, only 247 being received from the United Kingdom. During the six months, April to September, 1920, the number of motor cars imported was 7498, valued at 308 lakhs of rupees, Bombay imported 2775 cars, Bengal 2694, Madras 908, Sind 590 and Burma 531.

Twenty-two More Tractors Undergo Nebraska Tests

Nearly all require some adjustments during tests. While difficulties are mostly of a minor nature, the need for intelligent instructions to users and adequate provision for service are again evidenced. Nearly all firms given to extravagant statements in advertising matter.

TWENTY-TWO more tractors have satisfactorily completed the official test required under the Nebraska State Law before the tractor can be marketed in the State. A summary of the results of the test is given in the accompanying table, this supplementing the previous reports which appeared in the issues of AUTOMOTIVE INDUSTRIES for Sept. 2 and Dec. 30, 1920.

In the summaries of the tests already printed little has been said concerning the matter of adjustments and repairs, although the official reports devote some space to listing items of this nature that proved necessary or were considered desirable by the manufacturers during the test. An analysis of this portion of the report shows that very few tractors were able to complete the test, or the preliminary run for limbering up which preceded the test, without some change, adjustment, repair or replacement. Of the twenty-two tractors tested in accordance with reports summarized herewith no less than ten required adjustment or re-grinding of the valves before the tests were completed. Seven were in trouble due to over-heating or required some change or adjustment in the cooling system. Of these several experienced some trouble with the fan or fan belt, and others with parts of the water pump or circulating system. Eight tractors had spark plug trouble, or considered it desirable to replace or clean plugs during the test. Some tractors blew out as many as five plugs in the endurance test.

Cleaning or some adjustment or change in the air-cleaner or carbureter system was required on seven tractors. Five required adjustments to the clutch, chiefly to prevent slipping, while four had difficulty in lubrication of individual bearings or with some part of the engine lubrication system. Unsatisfactory lubrication caused the burning out or scoring of bearings on two tractors, and one required adjustment of the connecting-rod bearings.

The ignition system on four machines required repair, adjustment or replacement during the test. Three machines had piston ring trouble, and found it desirable to replace or repair rings. In three other machines the gearing gave some difficulty, in one case a key which had fallen out requiring replacement. The governor was the cause of trouble on three machines and two others had trouble with the fuel supply system, one from a leaking tank, and the other from a clogged gasoline pipe. In one case the cylinder heads of the engine cracked and were replaced. In several cases the cylinder heads were removed for inspection purposes and required new gaskets when the head was replaced.

While in all cases covered by reports here summarized the repairs and adjustments required were not considered sufficient to disqualify the tractor, the results make it plain that the tractor user must expect to make adjustments, replacements or repairs to the machine in normal use, and should therefore make it a point to know the machine and be prepared to keep it in operable condition.

Furthermore, it is apparent (if further evidence is needed) that the manufacturer who expects his machine to give satisfaction to the user must insist upon the distributer or dealer preparing for and giving prompt and intelligent service.

This service should start by seeing to it that the purchaser is fully instructed in the operation and care of the machine at the time of or prior to its delivery.

Prof. Oscar W. Sjorgren, chairman of the Agricultural Engineering Department, of the University of Nebraska, who had general supervision of the tests, recently presented a paper before the American Society of Agricultural Engineers in which the following particulars were given:

Of the 68 tractors which appeared for test 39 went through without any changes, while 29 made changes as follows: Eleven have changed or will be required to change their rating, 6 increased the rated engine speed, 11 changed some item of equipment and 3 withdrew after the preliminary test. Of the 11 which changed equipment, 2 also changed their rating. One of those which withdrew later made a re-application, reappeared and finished the test. These results indicate the necessity for a method of intelligently testing and rating tractors. These tractors have all been tested under conditions as nearly uniform as it is possible to secure, by a competent and unbiased force of men.

It is interesting to note how few of the large number of tractors tested conformed to the recommended standards of the S. A. E. and the A. S. A. E. The standards as to horsepower ratings read as follows: "The drawbar rating shall be 80 per cent of the horsepower that the tractor is guaranteed to develop at the drawbar continuously for 2 hours, the tractors being in good condition and properly operated at rated engine speed. The belt horsepower rating shall be 80 per cent of the horsepower the engine is guaranteed to deliver at the belt pulling continuously for two hours, the tractor being in good condition and properly operated at rated engine speed."

Of the 65 tractors tested only one was rated at between 60 and 70 per cent of the maximum power it proved capable of developing, 10 were rated at between 70.1 and 80 per cent maximum power, 21 between 80.1 and 90 per cent, 23 between 90.1 and 100, and 7 above 100 per cent of the maximum power they proved capable of developing at the belt.

Three tractors were not rated. Thus it is seen that only 11 machines fall within the set standard, while 51

*In engine only. The reports give kind of oil and amount used in transmission.

machines carry a rating higher than permitted by the standard.

On the drawbar work it was found that in all but two instances no difficulty was had in securing the rated drawbar horsepower if the rated belt horsepower was developed. The maximum drawbar horsepower was not obtained through any extended period, but the rated load was carried for ten hours.

In these tests 7 tractors were rated at between 50 and 60 per cent of the maximum drawbar horsepower they proved capable of developing, 12 between 60.1 and 70 per cent, 25 between 70.1 and 80 per cent, 9 between 80.1 and 90 per cent, 5 between 90.1 and 100 per cent and 2 above 100 per cent of the maximum drawbar horsepower they proved capable of developing. Five tractors had no drawbar ratings.

Thus it is seen that 45 tractors fall within the standards set for the drawbar rating as compared to only 7 falling in this class on the belt tests. Seventeen carry a rating higher than the standard, 2 of these being rated at more than they can actually develop.

Belt Speed

A very great variation exists in the belt speeds employed by different tractors as indicated by the following:

	Tractors
Less than 2000 ft. per min.	2
2000 to 2199 ft. per min.	5
2200 to 2399 ft. per min.	2
2400 to 2599 ft. per min.	6
2600 to 2799 ft. per min.	13
2800 to 2999 ft. per min.	6
3000 to 3199 ft. per min.	7
3200 to 3399 ft. per min.	9
3400 to 3599 ft. per min.	7
3600 to 3799 ft. per min.	1
3800 to 3999 ft. per min.	3
Above 4000 ft. per min.	3

The following comments concerning advertising matter put out by the various manufacturers who build the machines, tests of which are summarized herewith are contained in the official reports and indicate that many of the builders are given to the use of exaggerations or claims not substantiated by satisfactory evidence:

Test No. 20—Emerson-Brantingham 12-20. In the advertising literature submitted with the application for test of this tractor, we find some statements and claims that cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable.

Test No. 28—Beeman Model G. Remarks same as for Test No. 20.

Test No. 48—Twin City 40-65. In the advertising literature submitted with the application for test of this tractor, we find some claims and statements which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these claims or statements are unreasonable or excessive except the following:

"This 65 hp. engine is perfectly governed."

Test No. 51—Lauson 15-30. In the advertising literature submitted with the application for test of this tractor, we find some claims and statements which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"Whether running idle or on the full load, the Lauson burns *all* the kerosene."

"The Lauson burns every particle of kerosene. This close regulation makes every drop of fuel count and *there is positively no waste.*"

Test No. 52—Flour City 40-70. In the advertising literature submitted with the application for test of this tractor, we find some statements and claims which cannot be directly compared with the results of this test. It is our opinion that none of these are unreasonable or excessive except the following:

"There seems to be no load too great for it to pull."

"The gears are made—and they are *unequalled* for substantiability and long life."

Test No. 53—Allwork 14-28. Remarks same as for Test No. 20.

Test No. 54—Allis-Chalmers 6-12. In the advertising literature submitted with the application for test of this tractor we find some statements and claims which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"To-day it stands forth—as the most efficient small power unit available."

"There is no loss of power, no deadweight, no lost motion in the Allis-Chalmers general purpose tractor."

Test No. 55—Allis-Chalmers 18-30. Remarks same as for Test No. 20.

Test No. 56—Monarch 18-30. In the advertising literature submitted with the application for test of this tractor, we find some claims and statements which cannot be directly compared with the results of this test as reported above. It is our opinion that these are not excessive or unreasonable, except the following:

"The Monarch will go *anywhere*."

Test No. 57—Avery Single Row Cultivator 5-10. In the advertising literature submitted with the application for test of this tractor, we find some claims and statements which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"The Avery Motor Cultivator is the only real successful cultivator on the market to-day, as it leads the field in power, durability, simplicity, etc., over *any* cultivator built."

Test No. 58—Avery 18-36. In the advertising literature submitted with the application for test of this tractor, we find some claims and statements which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"Avery tractors have motors with patented gasifiers that turn kerosene or distillate into gas and burn it all."

"———Avery—is the—most efficient belt and drawbar transmission system built."

"———Avery—is the most 'direct drive' transmission system built."

"——a larger percentage of the power developed by the motor in Avery tractor is delivered to the belt wheel and to the drawbar than in any other tractor built."

"——Avery opposed motors are superior to any tractor motor built."

"The opposed type of motor—is much better adapted for use in tractor work."

"The fuel system used on the Avery tractors from the 8-16 hp. to the 40-80 hp. size burns kerosene, distillate or any other low grade fuel more successfully than it has been ever done before."

"—Avery tractors are the simplest tractors built."

"Averys are the best all-around drawbar and belt tractors built."

Test No. 59—Holt T-11. Starting the "limbering up" run, the tractor was operated in mud. It pulled about three-fourths of its rated load the entire twelve hours.

Test No. 60—Bates Steel Mule, Model D, 15-22. During the "limbering up" run, the tractor was operated in mud for about 8 hours, pulling about three-quarter load.

In the advertising literature submitted with the application for test of this tractor, we find some statements and claims which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"The Bates Steel Mule is the most efficient tractor in America to-day, barring none."

"The Bates Steel Mule will always work equally well in dry or wet soil, good or bad condition."

"The Bates Steel Mule is a *perfect* field machine."

Test No. 61—Holt Model T-16, 40-60. This tractor was operated in mud during the last eight hours of the "limbering up" run, pulling about three-fourths of its rated load.

Test No. 62—Indiana 5-10. In the advertising literature submitted with the application for test of this tractor, we find some statements and claims which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"The Indiana is the nearest perfect power plant for the farm use."

"No other tractor can anywhere near approach the amount of work which can be performed by an Indiana in a whole season on the farm——."

"Mechanically the Indiana is right."

Test No. 63—Townsend 15-30. In the advertising literature submitted with the application for test of this tractor, we find some statements and claims which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"The Townsend transmission is as near frictionless—All power is delivered at the drawbar, etc.——."

"That it will stand the hardest use without falter or need of repair or attention."

"Townsend patented carbureter is one of the most economical and thorough burners of kerosene possible to obtain. There is a remarkable *freedom from carbon or smoke*, etc."

Test No. 64—Uncle Sam 20-30. Remarks same as for Test No. 20.

Test No. 65—Toro 6-10. Remarks same as for Test No. 20.

Test No. 66—Square Turn 18-35. In the first tractor submitted for test, the motor was found defective, and the company was allowed to substitute another tractor.

During the rated drawbar test one-half of track was sprinkled but tractor was hard to control with one wheel on slightly damp soil, so sprinkling was discontinued.

In the advertising literature submitted with application for test of this tractor, we find some statements and claims which cannot be directly compared with the results of this test as reported above. It is our opinion that none of these are excessive or unreasonable except the following:

"In the Square Turn we use the well-known Climax engine. Because of its superior design—it has earned the reputation of being practically 'trouble-proof.'"

"First you have—but turning three 14-inch furrows 10 inches deep under practically all soil conditions."

"It will always transmit the power of the motor *without loss* and without slippage."

Test No. 67—Twin City 20-35. Remarks same as for Test No. 20.

Test No. 68—Bates Steel Mule 15-22. Remarks same as for Test No. 60.

Test No. 69—Port Huron 12-25. Remarks same as for Test No. 20.

Ford Tractors in Germany

IN connection with the report that the Ford Company was in negotiation with the firm of Ehrich & Graetz, Berlin, for the establishment in Germany of works for the production of farm tractors, the *Berliner Zeitung* learns from the latter firm that the report is correct. It appears that the motors will be imported from America, but that the other parts of the tractors will be produced in Germany according to Ford specifications. The complete tractors will then be assembled in German factories built or bought by the Ford Company. For the time being only tractors will be manufactured, but the eventual production of motor cars also is contemplated. During the first year only ten or twenty tractors will be turned out daily, but it is hoped to increase this number considerably in two years time.

ONE of the five fellowships in Highway Engineering and Highway Transport recently awarded by the University of Michigan went to Chia T. Yeh, a Chinese engineer who has been taking the special highway course at Ann Arbor. If Yeh returns to China and exerts the influence this fellowship should give him, it should increase the prospective sale of many motor vehicles there.

A Revolving Air-Cooled Engine

Has cylinder axes parallel to axis of rotation and utilizes wobbling-plate principle. Is of four cycle type but has planetary gear so arranged that engine makes one revolution for two revolutions of plate, thus combining high piston speed with low rotative speed. Single sleeve valve of cast iron is employed in each of five aluminum cylinders.

THE wobbling plate is an old mechanism that was probably first used in steam engines with a view to doing away with the crankshaft, which is considered an inefficient device by some inventors. The argument against the crankshaft is that at the moment of greatest pressure in the cylinder it affords no effective torque arm, so that it is impossible to get a tangential effort on the shaft. We now realize that this objection to the crankshaft is based on a misconception.

But while the wobbling plate may not be inherently superior to the crankshaft for transforming reciprocating into rotary motion, it makes possible a type of engine which can be easily air-cooled and which, on account of the absence of a flywheel, can be built very light. Several gasoline engines of this type, intended for automobile service, have been built in the past. In 1912 M. Canton Unne of France constructed such an engine which was extensively featured in the trade press at the time. In this the motion of the wobbling disk was transmitted through a pair of bevel gears. In this country during the early period of the war the Macomber car, which had an engine of this type, was advertised extensively.

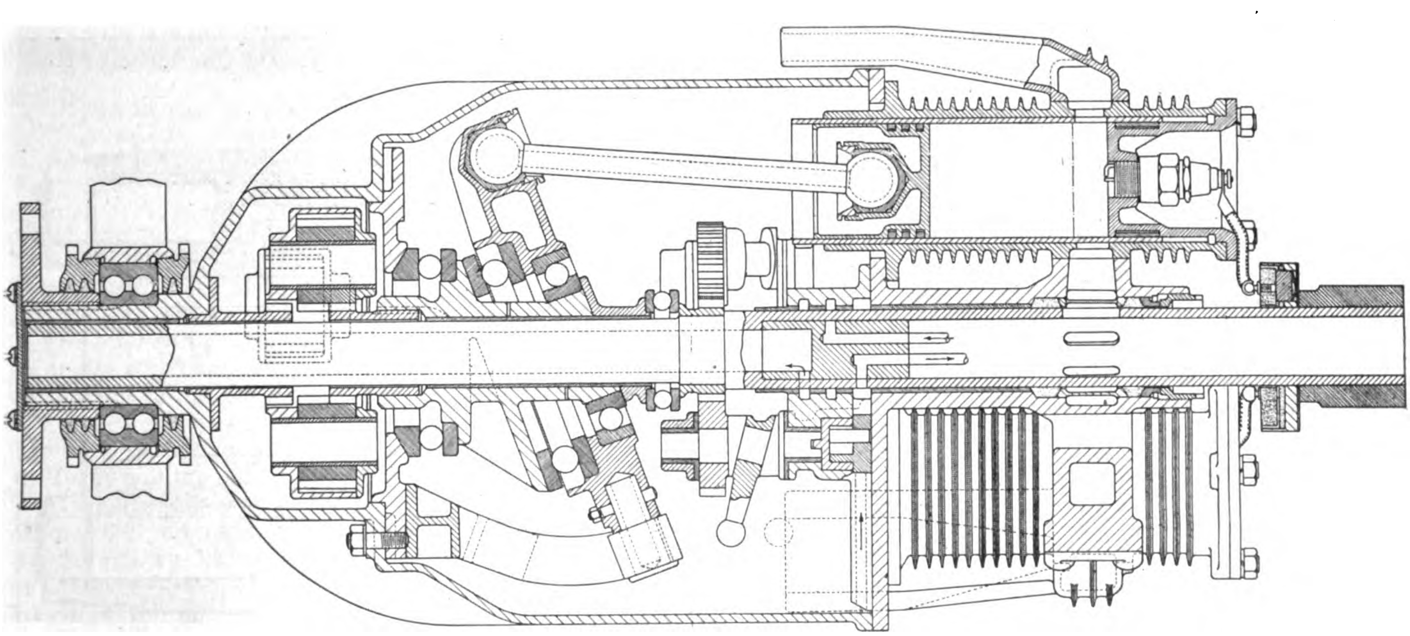
Judged by our present practice, a wabbling disk type is an engine of quite radical design, but it is clear that, in certain forms at least, it offers important advantages. Since the whole engine revolves, no separate flywheel is required. Still, if a moderate number of cylinders is used, the distance of the cylinder axes from the axis of rotation can be kept small, so there need be no excessive strains due to centrifugal force.

Owing to the rotary motion of the cylinders, they can readily be air cooled without fans or blowers, though, as in radial rotating engines, the leading and trailing sides are probably cooled somewhat unequally.

A new design of wobble plate engine has been evolved by the Nedoma-Najder Motor Syndicate and is illustrated by the sectional view herewith. This apparently represents a considerable advance over previous designs. By a special arrangement of the wobbling disk, its rate of wobbling is doubled, so that, although the cylinders operate on the four-stroke principle, there is one explosion in each cylinder for each revolution of the engine. This is an original feature and evidently makes it possible to combine high piston speed with a moderate speed of revolution, both of which are desirable, the first, because it results in high power per unit of displacement and in the high thermal efficiency and the second, because it reduces the strain due to centrifugal force on the engine structure.

Poppet valves are not very suitable for use in a revolving engine, owing to the effect of centrifugal force on their operation. In the engine here described a single sleeve type of valve is employed which has a combined rocking and reciprocating motion.

Referring to the accompanying sectional view, the whole engine is supported on a stationary hollow shaft, the forward end of which is held rigidly on a cross member of the frame. Combustible charge enters this hollow shaft at forward end and flows through ports in wall into a passage leading to the cylinder inlet ports, the opening and closing of which are controlled by the single sleeve valve.



Nedoma-Najder revolving air-cooled wobbling plate engine

The five cylinders, which have a bore of 2¾ and a stroke of 3⅜ in., are cast of aluminum with the cooling ribs integral. Into the outer ends of these cylinders are fitted cylinder heads of a form similar to those used in Knight engines, there being an annular space between the cylinder head and the cylinder wall into which the sleeve extends. The spark plugs are located centrally in the cylinder heads. The valve sleeves are made of cast iron and the pistons within them of aluminum. The connecting rods are tubular, with spherical heads, which are fitted respectively into the piston and into sockets of the wobbling disk. The wobbling disk is held against rotary motion relative to the cylinders by a guide secured to the engine housing and extending through a slot of the disk. The disk is supported on two ball bearings mounted upon a hub surrounding the stationary shaft. At the left-hand end of the engine there is a sort of differential gear of the spur type, one member of which is rigidly secured to the stationary shaft. This gear assembly causes the hub to revolve in the opposite direction to that of the engine frame at the same speed. It is this mechanism which causes the disk to wobble at twice the rate at which the engine revolves.

The valve sleeves are actuated by a set of five gears, supported in bearings carried on the engine frame. These gears mesh with a central gear on the stationary supporting shaft and, as the engine housing revolves, the five gears are caused to roll on the stationary gear. These five gears are mounted on shafts which are cut with inclined circular grooves, whereby a compound motion is given to lever arms, which connect by links to the valve sleeves. Three of these valve gear shafts are used to operate oil pumps, of which two serve to drain the engine case of oil, while the third forces the oil to all the bearing surfaces. The oil is contained in an outside reservoir which may be provided with cooling ribs, if desired. It passes between this reservoir and the engine through tubes extending through the hollow shaft.

The engine here shown is expected to develop 40 hp. at 1400 r.p.m. and to weigh 160 lb. Its firing order is 1, 4, 2, 5, 3. The power is taken off by means of the flange at the left-hand end which is keyed to a hub on the engine housing. Inclined flanges are cast onto the engine housing to facilitate cooling. The whole engine will be enclosed in a sheet metal stationary housing and the exhaust from the five cylinders takes place directly into this housing. The housing is supported by the channel type frame.

Spring Shackles Require Lateral Rigidity

SPRING shackles should be made quite rigid in a lateral direction as they are subjected to severe stresses when the car is driven around a corner at considerable speed, and particularly when it strikes an obstruction while skidding. F. Strickland in an article in *Engineering* points out that in one respect it is advisable to make the shackles long, as this reduces their angular motion on the pins and consequently the wear, but the requirement of lateral rigidity limits the length. He shows three constructions of varying degrees of rigidity.

Fig. 1 shows the simplest form of spring shackle. This was used on one make of vehicle in war service and proved the reverse of durable, but has the merit of being very cheap to make and therefore to renew. It will be seen that it fails completely to fulfill the condition of lateral rigidity. The result therefore is that the pins rapidly get loose in the shackles and the latter then cut into the pins, while the holes wear oval. The shackles as well as the pins have then to be scrapped.

It is possible that this type of shackle could be made satisfactory if constructed as shown in Fig. 2, as considerable lateral rigidity could be obtained while all parts would still be cheap to make.

The more usual form of shackle is shown in Fig. 3. The difficulty here is that each pin has to be a push fit in the eyes, and unless this is very accurate the pin gets "alive" in the eye and rapidly wears the hole oval, in which case both shackle and pin must be scrapped.

The satisfactory working of this type of shackle depends very largely on the proportions and workmanship. If the size of the parts is ample and the work good the shackle may be very durable, but if, to save weight, the parts are made small there is considerable wear. The pins should in all cases be case-hardened and ground.

IN a recent Bureau of Standards circular (No. 89) by C. E. Waters it is pointed out that the term carbon as applied to the incrustation in internal combustion engine cylinders is a misnomer, because the deposits consist largely of asphaltic matter.

The Manufacture of Magneto Magnets

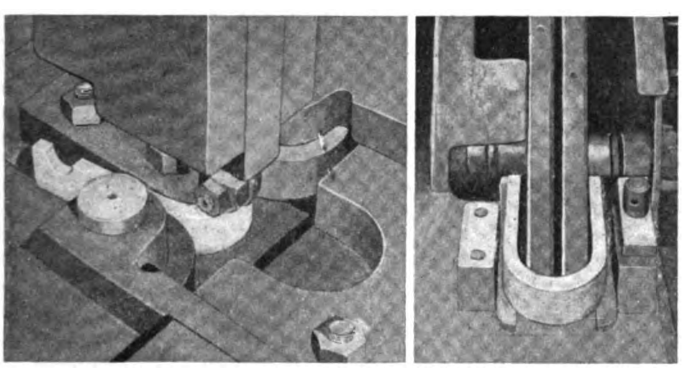
Production of U-shaped magnets from bar stock in large quantity is feature of Splitdorf plant. Forming, grinding, heat treating and testing operations systematized and under careful inspection. Magnetic strength of each piece measured in order to maintain standard.

By P. M. Heldt

ONE of the advantages of specialized manufacture is that equipment can be installed for economical production far beyond the possibilities where a great variety of products are turned out. However, economy of production is not the only advantage of such highly developed equipment, as accuracy of product and uniformity of quality are also secured as a rule.

The above remarks are motivated by a recent visit to the plant of the Splitdorf Electrical Co. The company manufactures its own steel magnets from bar steel and has developed a manufacturing process which is both economical and efficient.

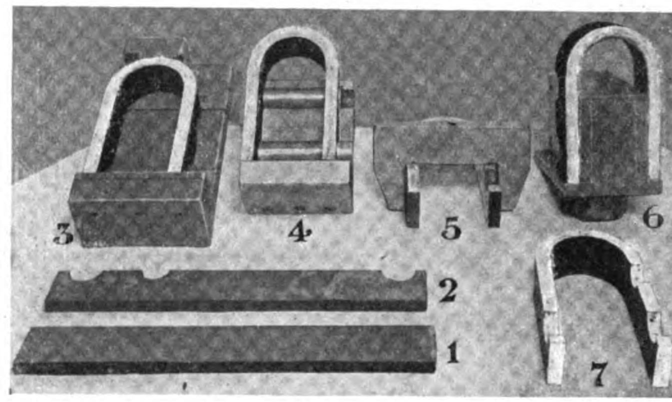
The magnet steel is received in the form of bars, which are sheared off to the proper length. These lengths of steel bar are next heated in a furnace to the working temperature. The passage through the furnace is continuous. Next the bars are put into a press in which half circles are punched out for the openings through which the rotor shaft extends. From this press the bars are transferred to a bulldozer, where they are bent up into U shape in a single operation. Both the punching and bending up into U form are accomplished during a single heat.



Left—Close up view of magnet just after being pressed in magnet forming machine. Right—Magnet set in grinding machine. (This apparatus grinds the inside of each leg of the magnets)

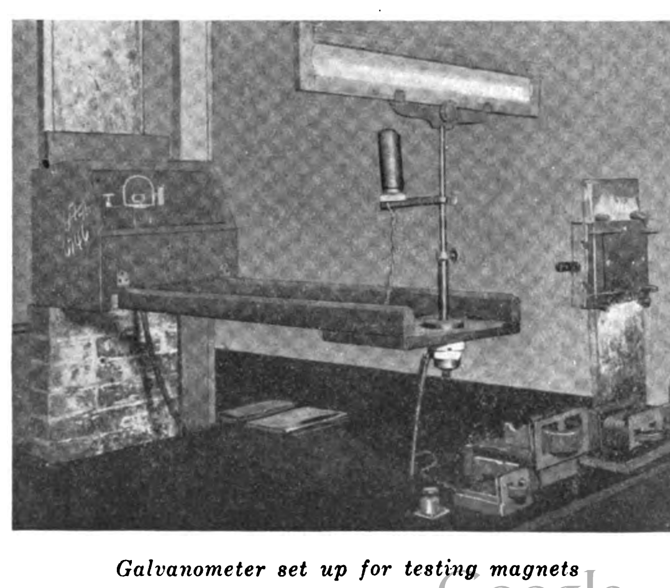
For quenching and hardening, the bars are pre-heated in another furnace, and during this operation they are held in tongues to protect them against warpage. The magnets are quenched by hand individually, the workman swinging them to and fro in the quenching bath, so as to insure uniform cooling and uniform hardness.

After coming out of the oil bath, the magnets are cleansed of oil in sawdust. Next, they are subjected to a preliminary bumping test, in order to show up any possible cracks or other imperfections. This consists in knocking the magnets together two and two. In another operation in the punch, following the bumping test, the legs of the magnets are bent in a little in order to provide stock for grinding on the inside. This gives the surface to which the bearing holder is fitted, this latter forming a part of the magnetic circuit.

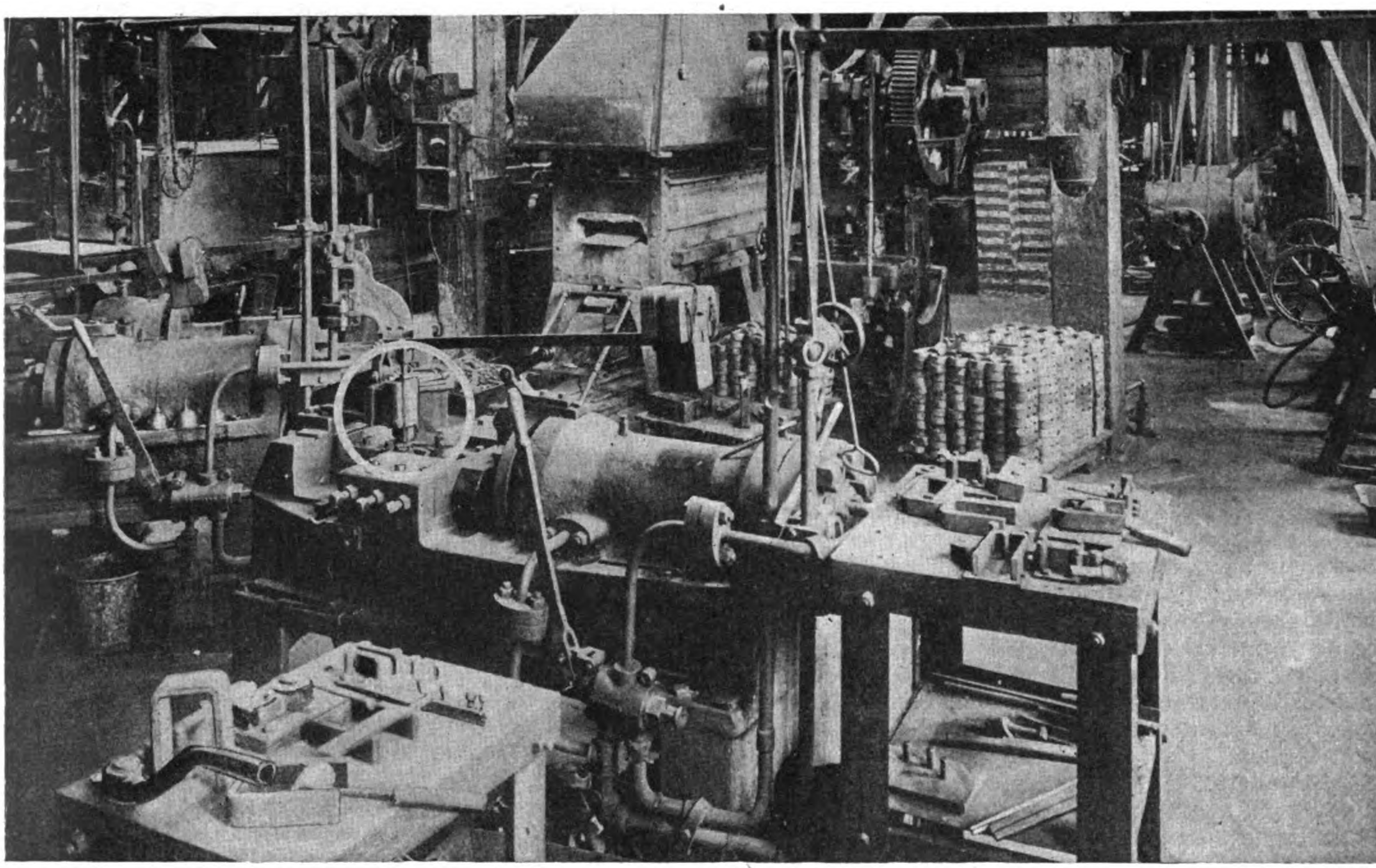


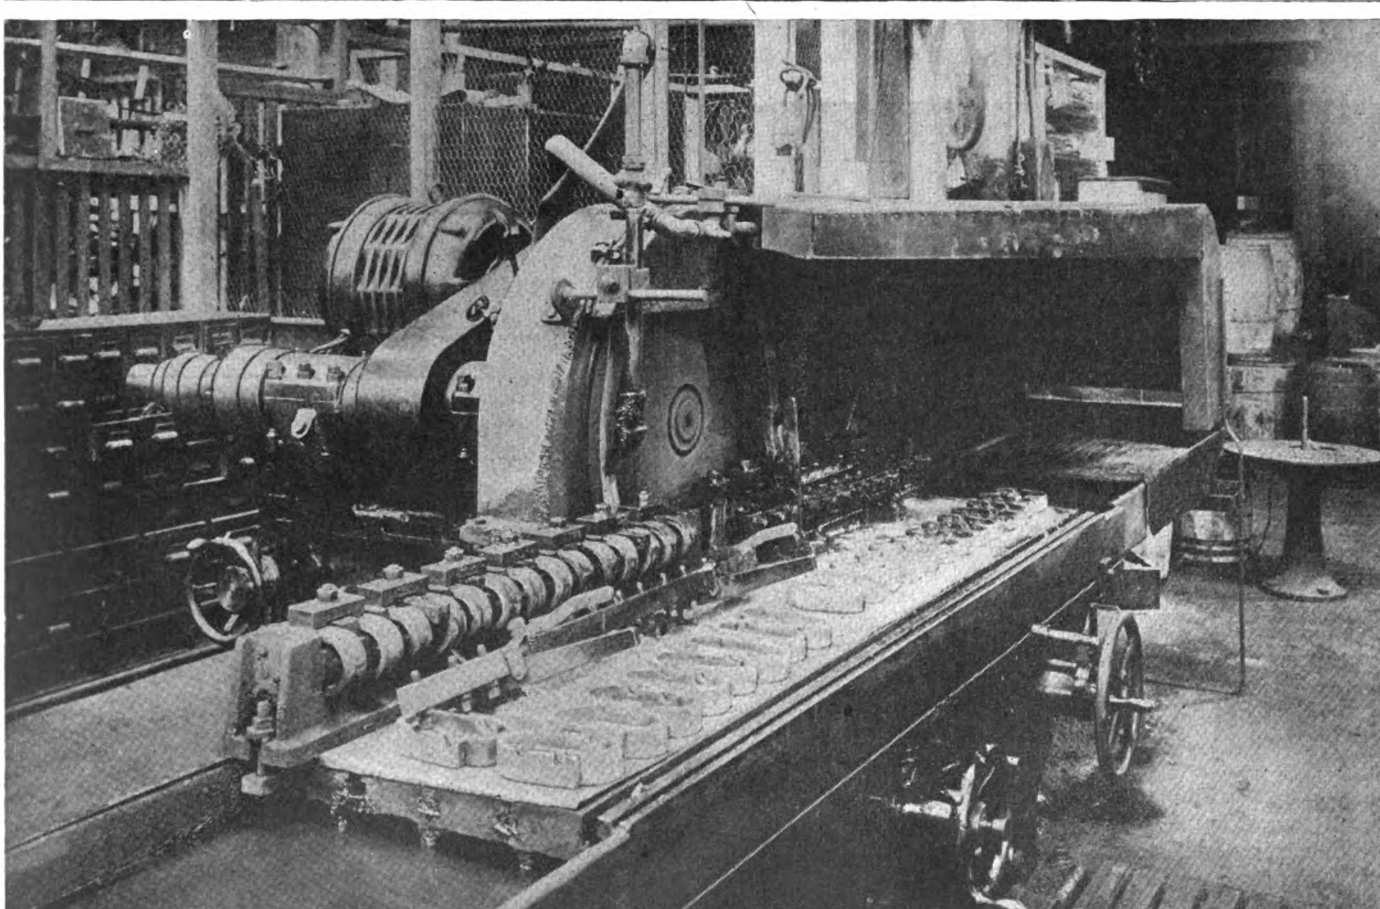
1—Plain bars of steel from which magnet is formed. 2—Semi-circular holes punched, to allow projection of rotor. 3—Magnet formed in gage for height. 4—Magnet formed in gage for hole size. 5—Magnet formed in gage for distance between outside of poles. 6—Magnet formed in gage for distance between inside of poles. 7—Finished magnet

Next comes the rough grinding of the outside of the magnet. First one side of the U is ground off, to get a surface to work from; then the other side, and finally the ends of the legs are ground off square. This completes the mechanical operations on the magnet.



Galvanometer set up for testing magnets





Upper—Forming machine and hardening department. A magnet just formed is seen within the circle marked on the forming machine in the foreground. Lower—Machine used for grinding off ends of magnets. This is a surface grinder and has a capacity of 2500 magnets per day

Magnetizing is accomplished on each magnet individually, the horseshoe being placed in a double coil magnetizing device, which is provided with an armature at one end. When the magnet is in position a switch is closed momentarily.

After the magnetizing process, each magnet is subjected to a test to show its magnetic strength, and any magnet not showing at least 20,000 magnetic lines is either remagnetized or rejected. The test is made by means of an induction coil connected to a ballistic galvanometer. The coil is wound on a rectangular frame, so arranged that the magnet can be inserted and quickly withdrawn. The withdrawal of the magnet causes the coil to be cut by the entire flux of the magnet, with the result that an electric impulse is induced in the coil, which is directly proportional to the total number of lines of force, and independent of the speed of withdrawal. This electric impulse passes through the coil of the ballistic galvanometer, the movable system of which is comparatively heavy, so that its period of swing is much greater than the duration of the electric impulse following the withdrawal of the magnet.

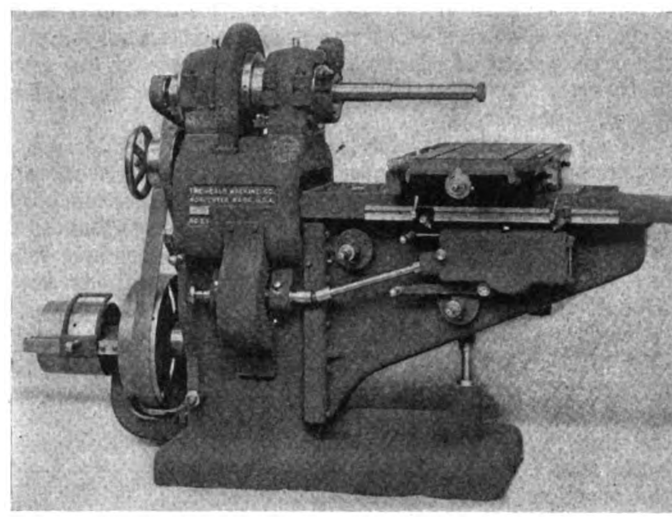
The galvanometer is of the mirror type, and is provided with a scale at some distance in front of it. Behind the scale is arranged a light, in such a manner that a beam from the light falls on the mirror and is reflected onto the scale. Owing to the slow rate of swing of the movable system, the maximum reflection can be easily read off. The scale is graduated directly in thousands of lines of force.

Simplified Cylinder Grinding Machine

A DEMAND for a simpler and smaller cylinder grinding machine has been met by the Heald Machine Co. by bringing out a new design in which the speed boxes and other expensive units are omitted, the drive being from a single shaft at the rear of the machine. The machine is self-contained and does not require a countershaft.

The machine embodies many of the features of earlier types. In addition to simplifying it and bringing down the price, the Heald company has increased the width of the knee and main table, so that when grinding six-cylinder blocks there is no undue overhang on either side when grinding the bores at the ends. Another change consists in an increase in the distance between the center line of the grinding spindle and the top of the cross slide table. On earlier machines this distance ranges between 4¼ and 7½ in. but on the new one it ranges between 7 and 9½ in. This makes it very convenient when grinding very large castings.

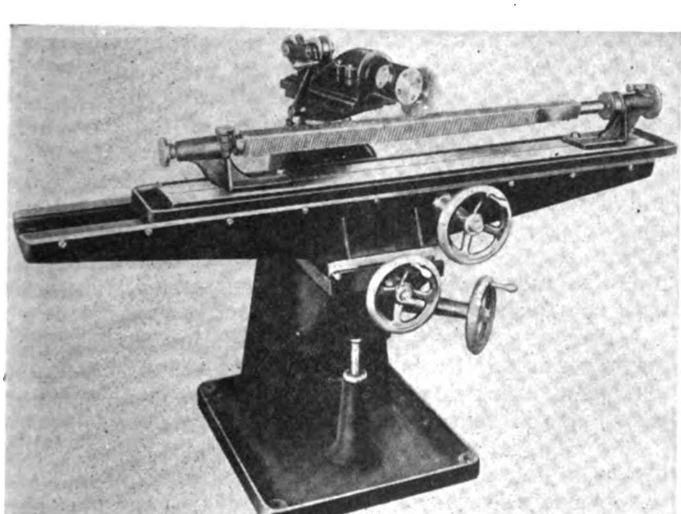
The eccentric and spindle arrangement is the same as heretofore. An arm, which grinds holes 2⅜ in. and larger in diameter by 11 in. long, is furnished as regular equipment with this machine. It also grinds holes 3 in. in diameter and larger 18 in. long. Other size arms can be substituted if the work requires it. The machine is designed specially to meet the requirements of shops doing a variety of work.



The Heald simplified type of cylinder grinder

A Grinder for Broaches

A GRINDER specially designed for sharpening broaches is being marketed by the J. N. Lapointe Co. It consists of a solid column supporting a vertically adjustable knee. This knee carries a table having both cross and longitudinal hand feed. The grinder has a head and a foot-stock which can be removed when it is desired to clamp square broaches and keyway cutter bars. The head-stock comprises an index mechanism for use when grinding spline broaches, and a live center which is belt-driven from an auxiliary countershaft. A three-story cone pulley on both the main and the auxiliary countershaft gives three possible speeds to the live center spindle on the grinder table. The table is large enough to grind broaches 64 in. long and 8 in. in diameter.



The Lapointe broach grinder

The grinding wheel is carried on a spindle supported by a swivel-head which makes it possible to both grind the rake angle on the back of the broach teeth and to undercut the faces. The head swings on the column of the machine to any horizontal angle, and so permits the grinding of teeth machined at any angle to the axis of the broach, as well as the grinding of teeth at the customary 90 deg. to the axis. The grinding wheel spindle is belt-driven from the main countershaft. A pair of idler pulleys change the direction of this belt for any angle of the grinding wheel spindle. The whole swivel head mechanism is moved forward by a hand lever to bring the grinding wheel up to the tooth surface to be ground.

Training Men for Tractor Service Work

Service is an extremely important part of tractor merchandising. Lack of proper service has hindered tractor development on more than one occasion. The present article describes the methods used by one manufacturer in training service men for his dealer and distributer organizations.

By Norman G. Shidle

EFFECTIVE service is an important feature in the merchandising of tractors: some authorities believe it to be the most important. It is of mutual benefit to the manufacturer, the dealer, and the user that proper service be available when the need for it arises. And in the development of effective service facilities by the manufacturer lies the possibility for a greatly widened and improved tractor market.

In an effort to develop men capable of rendering the proper service, some tractor manufacturers have installed training schools for dealer and distributer service men. Through such a school it is possible, not only to make the service man thoroughly familiar with the product itself, but also to "sell" him on the ideals and methods of the manufacturing organization. As a result, the manufacturer gets a closer relationship with his dealers and at the same time insures service to the user along the lines best suited to a promotion of good will for the product.

An excellent school has been developed along these lines at the Midwest Engine Company in connection with the Utilitor tractor. The course is conducted under the auspices of the factory service department of the Utilitor Division. It lasts for nine days, each class comprising about ten men. During the course, the students are made thoroughly familiar with the various technical details of the Utilitor, are instructed in the best methods of making repairs, spend a number of hours in practical work both in shop work and on a farm adjacent to the factory school.

While service on a very small machine such as the Utilitor does not involve as many complexities as would arise in connection with larger units, a story of this course is specially valuable because it is possible to get an entire picture of the school and the various training activities.

The course is particularly adaptable to description in a short article, since it involves all the factors in a small way which might be necessary in larger scope in training men for work on a large machine.

Most of the men who take this course are already familiar with the fundamentals of gas engine design and operation, most of them being dealer or distributer service men. The course is so designed, however, that salesmen and prospective salesmen, or men entirely unfamiliar with the technical phases of the tractor may also be included.

The school is in charge of a director who devotes his entire time to this work. It is supervised, however, by S. V. Harding, Service Director of the Utilitor Division. A description of the work in detail will indicate the thoroughness with which the ground is covered, taking into consideration the short duration of the course.

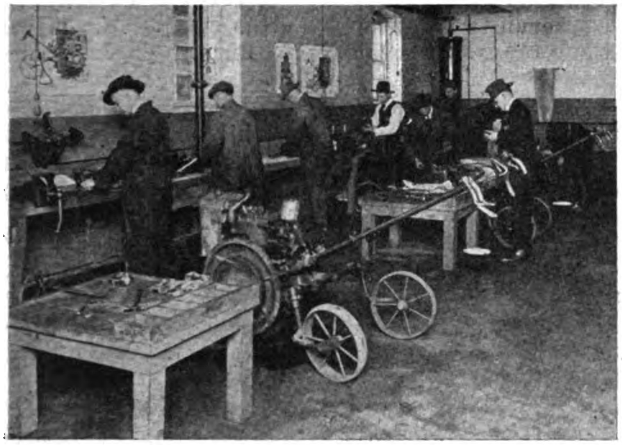
On the first day, after the new students have been enrolled, a general lecture on Utilitor service is presented. This brief talk introduces the men to the service ideals and aims of the company and forms a basis upon which the rest of the course is built up. The following paragraph from the first lecture indicates the kind of foundation that is laid:

"In addition to this education (of the user as regards his service obligations), the manufacturer group must maintain adequate supplies of spare parts at points easily accessible to Utilitor users, and it must have at hand men trained and qualified in the care, operation and repair of this product, whose services may be brought to the assistance of the Utilitors operating in the user's hands."

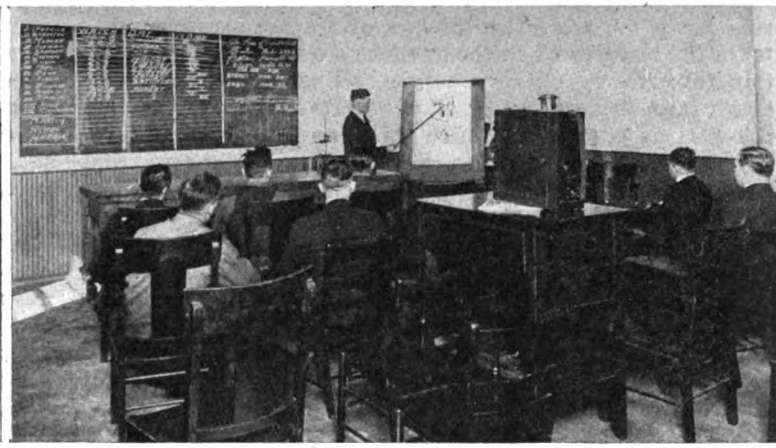
Following this lecture, is an illustrated talk on the principles of the gas engine. This talk traces rapidly the history of the combustion engine from its inception to the present state of refinement, and describes simply and briefly the fundamental principles of gas engine operation. The talk is illustrated by colored charts which present the material so clearly that it can be understood even by one comparatively unfamiliar with the functioning of gas engines.

A general survey of the plant is then made, the students being conducted through the various manufacturing departments and being instructed in a general way as regards the different operations.

The final part of the first day's work is taken up with disassembling the Utilitor, so that each student may learn the names and functions of each of the various parts. First, the instructor gives a talk on disassembly, taking



View in shop section of service school



The classroom of the service school

the machine apart to illustrate his various points. The students are encouraged to ask questions when any point is not clear, so that when this short lecture is finished, they should be capable of properly disassembling a machine themselves.

Following the lecture, each student is given a tractor and is expected to properly disassemble it. This he does entirely alone, the instructor, however, being present to answer questions and make explanations.

The second day begins with a lecture on Utilitor parts, illustrated in the same manner as was the lecture on gas engine principles. Following this talk, the students again go into the shop to actually do sub-assembly work. In this way they become familiar with the details of the various parts and become proficient, through actual experience, in assembling them.

The particular type of clutch used on this tractor is next discussed, first in a lecture and later in the shop. The students, after being taught the theoretical principles of the clutch are required to assemble and disassemble it. In every case, a clutch is given to each student so that he must do all the work on every unit himself.

The ignition and fuel system comes in for attention on the third day. The lecture on ignition which starts the day takes up the basic principles of ignition and explains the ignition system thoroughly in simplified terms. This lecture is followed by several hours of shop work on the ignition system.

The historical as well as the technical phases of the fuel system are explained to the students, the idea being to give them a broader knowledge and a more intelligent interest in the material things with which they are working each day. The parts and principles of the carbureter are discussed, questions are answered, and the entire matter made clear to every man. The last periods of this day are spent in reassembly of the entire machine. Each student again has a machine to himself and is required to assemble it from beginning to end.

Instruction is given in the proper methods of uncrating a machine at the beginning of the fourth day. It is possible for the dealer to uncrate the machine in such a way that the crate may be used over again. Improper methods, however, destroy the crate so that it is not fit for further use. For this reason an entire period is devoted to this phase of the work. After the lecture the students again go into the shop. The work done in the shop from this time on is likely to vary somewhat with the individual. Some men will grasp certain phases of the work more readily than others. In the shop work, each man works along the lines in which he is least proficient, so that he may have a clear and comprehensive grasp of all phases of the work when he has finished the course.

The lecture on hitches which follows, explains the various methods of hitching the Utilitor to the different farm implements. The students then spend several hours in making such hitches until each one becomes proficient.

A lecture on "trouble shooting" starts the work of the fifth day. In this lecture it is pointed out that three things are needed in order that an explosion may occur:

1. Pressure
2. Combustible mixture
3. Ignition

The students are then taught how to trace various troubles to a lack of one of these three essentials. Each man is given an engine which has been put out of order in some way. He must then locate the trouble and set it to rights. Several hours are spent in this work.

The "trouble shooting" work is followed by a lecture on the various power applications of this particular tractor. The men are taught the various ways in which the Utilitor can be used as a power plant. More practical work in "trouble shooting" follows this lecture.

The sixth and seventh days are spent "down on the farm." An experimental farm of about 17 acres is located within walking distance of the factory. Here the agricultural features of the hitches are demonstrated; the type of hitch best designed for a specific type of work is explained, etc. The students then make the various hitches, see the tractor used for various types of work, and operate it themselves under various conditions. Much of this day is spent in instruction talks and demonstrations by the instructor. The seventh day is a day of actual field work by the students. This day brings out the things that the student does not know and an opportunity is given him to clear up the cloudy spots in his knowledge.

The first period of the eighth day is an open conference with the director of the farm service department. A lecture is then given to show the best method of making a field demonstration, and of pointing out the outstanding features of the machine. A conference period follows during which the students may talk individually with the instructors concerning various phases of the work, and may go into the shop and work on some part of the tractor with which they are not yet thoroughly familiar.

Every student is taught how to run a motion picture machine. This firm has obtained excellent results through the use of motion pictures in advertising its product, and wishes at least one man in every dealer's and distributor's organization to be familiar with the operation of the picture machine.

The last period of this day is filled with a talk about spare parts, the necessity for a dealer's keeping on hand an adequate supply, the system of distribution used by

this company, and other phases of tractor service work.

On the last day of the course, the students make another trip through the factory assembly line. This time they are in a position to know all the parts and to understand the various operations which they see. It is, in a sense, a lecture tour during which the men ask questions and find out many new points which were not intelligible to them on their first trip at the beginning of the course.

A detailed lecture concerning the proper equipment necessary for a tractor service shop is given. The special tools necessary are named and described. When the student is through with this lecture he is able to go back home, start a service shop and intelligently order all the tools and equipment he will need to keep it operating efficiently.

The class is taken for a trip through the stock room. The man in charge of the stock room explains the stock-keeping system to them, points out the difficulties with which he meets, and thus makes them aware of the inevitable causes for delay which sometimes arise. This is not in the nature of excuses, but simply another method of getting the dealer's organization to understand the problems of the factory. The result has been a marked increase in the spirit of co-operation.

A final lecture by the service director, summing up the course and presenting the ideals and knowledge which the company hopes it has given the men, winds up the course. After this lecture informal conferences are held in which the students can ask and have answered any questions which may have come up and which they wish answered before returning home.

The results thus far obtained from this short intensive course have been excellent. It has resulted in a number of advantages to the company. Among the chief of these might be mentioned:

1. A better and more thorough knowledge of the product among dealer's service men.

2. A knowledge among these men of the best service practice for this particular product and a resulting betterment of the service rendered to users.

3. A raising of the ideals of service among the men who actually render that service to the user; a broadening of the vision and ideals of these men.

4. A better understanding by the dealer's organization of the factory problems, and vice versa. This makes for a smooth working organization throughout.

5. A personal acquaintanceship between the factory service manager and the various dealer service men. This is made possible by pleasant and close association during the ten days of the course. It is not only a personal pleasure for all concerned, but a distinct advantage to the efficient working of the service organization. It is an advantage that is abstract rather than material, but it is through that intangible human element that the best organizations are effected and the greatest tasks accomplished.

Several interesting points are brought out by this course from the standpoint of instruction methods. The instruction is given to more than one type of man, although a single type predominates. In order of the number which take the course, the following groups are comprised among the students in general:

1. Mechanics; men who are good artisans, but who have had little experience in listening to lectures or in taking notes. Men who are likely to grasp mechanical details rapidly and theoretical details slowly.

2. Salesmen; men being trained to sell the tractor; whose chief experience is selling; who are likely to grasp principles quickly and a technical practice less readily.

3. Executives of distributers' organizations; men likely to have the same characteristics as the second group mentioned, with the good points more highly accentuated.

To make the course adaptable to each of the classes, every subject is treated in simple form to begin with. It does not hurt those who are familiar with technical practice to renew their knowledge of fundamentals, and it enables the others to grasp the subsequent instruction. Then too, the latter part of the course, though definitely planned as to periods, allows considerable scope in the exact shop work to be done, so that the particular needs of each type of man can be adequately accommodated.

Insofar as possible the lectures are given early in the day; the first period is always a lecture. Thus the minds of the men are caught when they are fresh, and when they can most readily adapt themselves to the unusual ordeal of keeping the body still but the mind active.

When a man applies to enter the course, he is required to fill out the "Application for Membership" card shown in the accompanying illustration. When the man is a dealer or distributer employee, the director of the service school sends a letter, near the beginning of the course, to the man's employer, noting the arrival of the man and the prospects which he seems to have for successfully completing the study. In some cases, it may be obvious at once that the man does not have the requisite qualifications. Then the employer is notified in a frank and cordial manner. The man is allowed to take the course, but the employer then knows beforehand that he is unlikely to receive the maximum value from the training.

At the completion of the course, an examination is given. Those who pass it successfully are given a certificate of graduation. The service director then writes to the employer of the man another letter, reporting upon the work of the student during the course.

The school is conducted in three large rooms, one of them a shop, one an office, and one a classroom. These rooms are provided with the models, charts, classroom chairs, and other equipment necessary to provide the best facilities for such a course. The expense of conducting the course, providing equipment, instructors, etc., is borne by the company. The personal expenses of the student are borne by his employer.

To illustrate the thoroughness of the training, considering the very brief period devoted to it, a few sample questions from the final examinations are presented.

1. What is meant by ignition, how is it accomplished? What is preignition?
2. What becomes of the heat generated during power and compression stroke?
3. What is correct method of lubrication of magneto? Why should cylinder oil never be used?
4. What factors can be at fault to prevent the low tension current from completing its circuit?
5. Outline the Utilitor plan of distribution.
6. Explain thoroughly the Midwest service policy.
7. Name all publications in which you have seen national advertising of the Midwest Utilitor.
8. What function does the Utilitor clutch perform? What type of clutch is used? Has Utilitor separate set of transmission gears?

While these questions would not cause an engineer to think very long, it is evident that if a man is able to answer a majority of them correctly after a nine days training course, those nine days have been spent in very profitable effort.

This training plan is further carried out by requiring each distributer to maintain a similar course of training, conducted on a less elaborate scale, for his dealers. The dealers are also required to provide training for their own men as occasion requires. Thus the work of the central school is supplemented by two duplications. The main course, however, is always open to men from both dealer and distributer organizations, and draws many of its students from the first as well as the second.

Dealers Resentful Because of Expense on New Cars

This installment of our document on the relations of the manufacturer and dealers is confined to the dealers' opinions on assembly and inspection. As nine of the thirteen replies tell of heavy expenses, you can understand why the dealer is not cheerful on this subject.

By Clyde Jennings

MR. MANUFACTURER, have your cars been costing your distributers and dealers from $50 to $150 to put them in shape to be handed over to the customer?

No, this is not a foolish question. A lot of cars have been costing the dealers and distributers this amount and evidence at hand is that in many cases the factory has not in any way reimbursed the dealer for this expense.

In only four of the thirteen cases we will cite has the factory met this issue fairly. The four, you will note from a reading of the evidence, are dealers who handle only one car. Some of the others, you will note, handle more than one line.

A pretty bad situation, I grant you, and it is no wonder that some dealers and distributers are perfectly willing to change their lines.

It is one of the limitations of research that the results are never entirely up to date. We can obtain positive information only on what has happened and then, usually, only when it has happened long enough before to become a settled incident. It was for this reason that in a previous article we passed on to you a referendum on incidents that were ancient history. It would be very interesting to know to what extent the conditions reported in these replies have been corrected—now that the manufacturers have more time to give to details.

It is no secret that each manufacturer, as he reads these answers, is going to reflect in his mind that he is not the man referred to. But are you sure? How long has it been since you read the dealer complaint correspondence? It is to be hoped that all manufacturers who read these answers will read them with a perfect open mind and not influence himself as to his attitude.

Here is the question asked the dealers to get these replies:

Numerous reports indicate that poor assembly by factories has cost in many cases as high as $50 per car to put in suitable shape for customers and that the factories have not reimbursed dealer for poor factory work. Is this true?

THIS is the third of a series of manufacturer-dealer articles. These articles are intended to call to the attention of the manufacturer some of the conditions existing in the dealer field. They are not written for dealers.

We believe that it is time for better selling of automobiles.

We believe that errors can be corrected only when it is known that the errors exist.

We believe that much of the information in these articles will be real news to many manufacturers.

We believe that it is important that he should know these things.

There will be more of these articles—one of especial interest on the manufacturer-dealer contract.

Now we have taken the liberty of grading these replies from worst to best in a general way. Read these carefully, they are worth attention!

1—Our cars, particularly one model, have given us no end of trouble, and the service on this particular model has averaged us about $150 a car. Our factory has not as much as replaced parts. They would simply state that the parts were worn and not defective, and we had to replace these parts free for service policy. Our dealer organization, which cost us thousands of dollars to create, is in a most disorganized condition because of the trouble which this particular model has given, and being short of mechanics, we have simply been unable to give the dealer the help and co-operation which he should have, which burden should be on the factory's shoulders and not on ours.

—

2—The manufacturer ought to be ashamed of himself for delivering cars to the distributer and dealer which were only half assembled. The average cost to us for every small model Four that we have had delivered to us this year has cost us $60 per car to put it in a salable condition. I have distributer friends who tell me that it cost them $120 per car to put them in salable condition, and when we mention this fact to the manufacturers they say that their policy is that they absolutely will not reimburse any dealer for labor. This applies also to labor for replacing defective parts.

—

I am glad to say that the worst is past, but there are still some reports that are very embarrassing to legitimate manufacturers. Here are a few that will cause any thoughtful man to ask if there is any such correspondence in his office:

3—Poor assembly by the factories costing as high as $50, yes, even more, has been chronic with most manufacturers as well as the manufacturers with whom we do business. There is no question about this, and this is still continuing today, and the "buck" is passed to

the distributer and the dealer in each instance. There is no labor allowance given for rebuilding these cars and putting them in satisfactory condition for the customers. This obviously is very unfair. Factories will replace parts, but the transportation on these parts must be paid by the customer, and the labor charges for installing the same, even though the cars have seen little or no service. **This matter should be remedied, and the factories under their guarantee should take care of this item to build up a reputation for themselves and also allow the distributers and dealers to make money. This is one of the worst features of the business.**

—

4—It is quite true the majority of factories have given their cars very poor inspection, indeed, with the result that poor assembly has occurred in many cases. I believe that when you quote $50 per car as the cost to the dealer for taking care of this poor assembly, you are putting it very low. I know of a number of cases where the amount far exceeds that sum. In some cases the factories have taken care of this bill, but have not done so in the majority of instances.

—

5—The poor assembly of cars by factories, undoubtedly, has cost the dealers considerable money to put cars in suitable shape for deliveries, and not a single case of reimbursement has come to my knowledge.

—

6—This is a fact. Not only have the assemblies been poor, but we have had instances of equipment being short when it was self-evident that the cars were loaded that way. We have had to buy two or three clocks, and so forth. We have had to tear down several engines because of tight pistons. The factory is absolutely arbitrarily taking a position that it cannot err nor can any of its employees; therefore, if they do not, of their own accord, send us a Back Order, we have to pay the bill.

—

7—My last records show that it cost me about $75 per car to put the Blank in condition for customers, and we were never reimbursed one cent by the factory for labor. In addition to this, we have to pay express both ways on parts returned, but in most cases the parts were furnished free by the factory.

—

8—The assembly work in the aggregate has been poor. The inspection, as a rule, has been a joke, and it is acknowledged that most dealers before starting on their drive-aways inspect their cars before taking a chance on the road. However, our factories have made good any defect and have allowed us the credit to cover on the parts and, in some cases, the labor also was included in our credit.

—

9—It has been the custom ever since I have been in the business (11 years) for distributers to put the cars in condition to run at their own expense, and there has been very little change in the situation during the past several years.

—

Granted that you are a conscientious manufacturer, and that you have survived thus far, I am glad to say that there is better news coming. Very likely you had begun to think that you were in mighty bad company. But there are **some automotive manufacturers who have a right regard for the morals of business.** It is a great pleasure to pass these bits of testimony on to you:

10—We have had more or less difficulty from the condition referred to. No doubt, factories have been laboring under a very serious condition from a labor standpoint. We have had a great many cars come in that have been taken into the shop before we could deliver them. In some cases on our Blank cars, we have had to spend as much as $50 to condition them for delivery. We have found that these cases, however, are isolated, and in such cases we have taken the matter up with the factory, and in nearly all instances received entire satisfaction. We believe we are particularly fortunate in being connected with factories that have a very fair policy.

—

11—Poor assembly has not been a serious matter with us. Cars have been coming through comparatively O. K.

—

12—Our factories have co-operated with us to the last degree, in my estimation, in relation to anything that could be traced to poor factory work or poor assembly, as you put it. Two of our factories, on several occasions, reimbursed us for labor when it could be proven that the job was improperly done at the factory.

—

13—The Blank people prefer to shut down in preference to sending out badly assembled cars. We have experienced practically none of this, but have experienced delay in getting cars and waiting until they were properly assembled. We know, as a matter of fact, that lots of distributers and dealers have been put to the expense of a lot more than $50 a car to get their automobiles into commercial condition, and that the manufacturer has not reimbursed the dealer.

—

Just a word more in closing. It is to be hoped that manufacturers will not remember the last four testimonials and forget the others. Also it is to be hoped that they will not remember only the first two.

Our business is a great, big, fine business, and we have the foundation for a bigger and finer business, but some things that are happening in this structure are not entirely helpful. We must tear out the defective material put in during the last few years of stress and replace it with honest intentions, well carried out.

The strongest bond the manufacturer should weave should be that with the dealer. YOU cannot hope for success unless your dealers are for you and with you, heart and soul.

We are not yet through with this manufacturer-dealer situation.

THE trade mark law of 1920 has materially softened the harsh and apparently unreasonable conditions of the Trade Mark Act of 1905, under which so many trade marks constantly used in this country could not be legally protected. The old law did not permit of the legal registration of a trade mark that was descriptive or geographical. Such a trade mark might be adopted and used in this country and respected because of the popularity given it by advertising, but as it was not legally registered in this country any one could steal it for use in another country. Under the new law, such trade marks can be registered. An automobile, truck or tractor may now be registered under a trade mark that is descriptive or indicative of the city or State in which the vehicle is made. The greatest advantage of this law is that when a trade mark is so registered in this country, it cannot be as easily stolen in a foreign country as under the act of 1905. But to devise a trade mark that will be attractive and command respect in all countries is quite another matter and here is where the trade mark experts can well serve a firm that is going into the world trade field.

Some Interesting Bits of Information on Foreign Trade

No one has compiled a comprehensive directory on Foreign Trade and probably no one source of information will supply your needs. It is only by carefully compiling all bits of information that fit your case that you can study your export problem with the care and interest it warrants.

THE annual meeting of the National Foreign Trade Council, which will be held in Cleveland May 4 to 7 inclusive, should be of especial interest to automotive manufacturers this year. Surely no one will question the fact that the export trade has been an important factor during the past year, and there is every reason to believe that it will be even a more important factor in the years to come.

Export trade has peculiarities. A man versed in domestic trade is not always entirely equipped for export selling. There are many crooks and turns that must be learned and mastered. Experience is very slow in export trade, chiefly because the turnover is slow. It requires a long time to learn whether or not you have offended a customer. So, if you are in haste to get into foreign trade, it is best to learn by the experience of others. The meetings of the Foreign Trade Council serve that purpose.

Batteries Abroad

AN interesting development in foreign trading is the increased attention being given export trade by the storage battery companies. Several of these companies are establishing export agencies in many countries where sufficient American cars have been sold to warrant this attention. It is even more significant that these companies are establishing export agencies only where the agency will provide adequate service facilities.

The battery companies intimate that they have not received full support from the car manufacturers. The car exporter, it appears from the data in the possession of the battery exporters, has not realized fully the importance of primary information that should accompany cars shipped abroad. In some cases cars have been exported with wet batteries, instead of the special dry battery that is manufactured for export trade. As a result, when this car is turned over to the owner four months after it has left the factory, the battery is impotent. This is quite a serious defect in a country where the battery is so little understood as in most of the countries to which cars are exported. It not only is a blow at the battery maker, but what must be considered more important, is a blow at the confidence in the car and, generally speaking, to American cars as a whole.

Optional Equipment

IT is interesting to note that some very careful merchandisers of cars are going into the export business with a considerable understanding of the problems before them. Among the cars exhibited in New York during show week was a Marmon, which was designed especially for export trade. This car was at the Marmon dealer show room. The most marked feature of the car was that it was a right hand drive, but there were other optional features, designed to meet the wants of the public in the various countries of the world where the export division of the Marmon sales department may place the car.

Optional equipment is quite necessary for a successful foreign business. The need of right hand drives and magnetos is very well known. The matter of colors is also quite important. In only a few countries in the world is the buying public content to ride every day and on all occasions in the funereal appearing cars that predominate in the United States.

Car Census in Sweden

AN error in an article about Sweden as a market for automobiles, which was published in AUTOMOTIVE INDUSTRIES Dec. 2, has brought to us a number of letters, which go to show how seriously an error in AUTOMOTIVE INDUSTRIES is regarded, and which bring to us considerable information. These letters come from The Scandinavian-American Trading Co. of New York, Fiat Societa Anonima-Torino, Turin, Italy, and Capt. John Neren, editor *Motor*, Stockholm.

These letters all call attention that the figure of 70,000 is entirely too high for the number of automobiles in Sweden. This figure was printed as coming from the French Chamber of Commerce in Sweden. It is probable that in transmission of this information a typographical error made 7000 grow to 70,000.

The difficulty in reading this article by the correspondents was that the figure of 7000 is not high enough, and the mistake was not obvious. These letters inform us that on June 1 there was a census of motor cars in Sweden and that the number reached 8506. The Scandinavian-American Trading Co., which represents The White Co. in Sweden, adds that recent information indicates that the Jan. 1 registration will show between 13,000 and 13,500 cars and trucks in that country. This great increase is due to the heavy importations during 1920.

The details of the June 1, 1920, census were:

	Country	Stockholm
Cars and trucks	8,506	2,137
Motorcycles	9,059	1,015

Another bit of information in these communications is that the import duty on automobiles into Sweden is 15 per cent of the value c.i.f. at Swedish port, consequently this is inclusive also of the freight and insurance, railroad and boxing charges, and not as stated in the translated article.

Defense of American Car

AMERICAN car manufacturers who export to Australia have a firm friend, the editor of *The Australian Motorist*. This comment is brought out by an article which appeared in the Dec. 1 issue of that publication.

The comment was based upon a criticism of the Adelaide show, written by an anonymous correspondent. The editor apologizes for printing such a communication, but he interlards between the paragraphs of this criticism his own view of the points made by the critic.

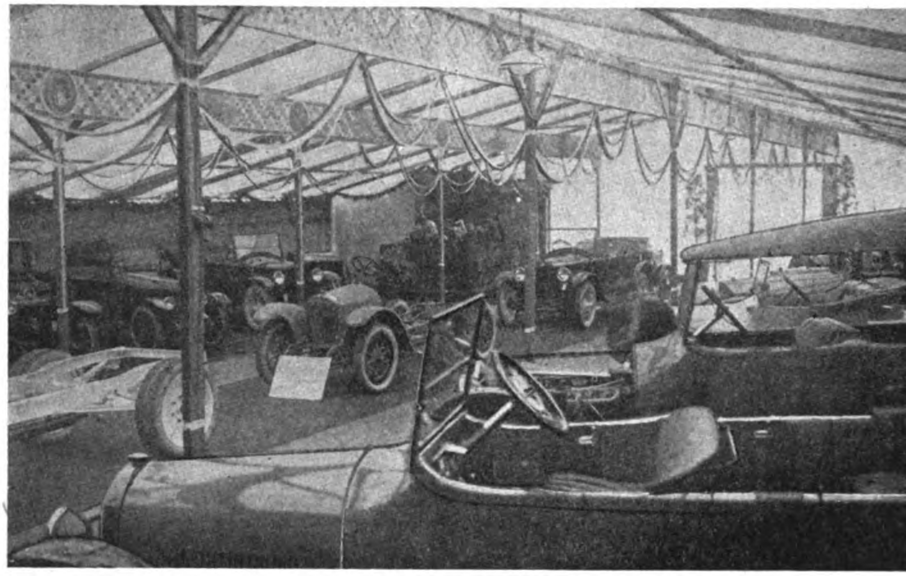
The critic is one of those persons who can be classed as pro-British. He apparently believes that Australians should not buy cars until the British manufacturers are ready to supply them. He let his antipathy for American cars carry him past the facts, for his statement that the show was financed by Americans and displayed more American cars than British are met with a mere statement of fact. We will reprint one paragraph of the criticism of the editor's reply as a type of the controversy.

The critic wrote:

"The British side of the show, though so limited in numbers, came in for a good share of attention, and undoubtedly the agents will be able to report business by the end of the week, in spite of the big difference between the cost of British and American cars. That the British car will hold its own again, and in the near future too, can be guaranteed. The British manufacturers have not recovered from the effect of the war yet, and may not do so for another season or more, but taking into consideration the many advantages America had while British interests were fighting the wars of the rest of the world, it is a marvel that we could even make a show at all."

The editor replied:

"When the British manufacturer gives Australians motor vehicles which come within the scope of the purchasing power of the Australians then British builders will get all the trade. The reason that fewer British cars are being purchased than American is due to the following: (1) A mail contractor with small capital cannot purchase a motor car for £1250, but he can finance one at between £300 and £650. (2) The farmer with heavy demands on his bank for agricultural machinery, fertilizers, and perhaps seed, when the drought catches him, cannot be expected to lay out over £1000 in a luxurious mechanical road vehicle if one costing a little more than half that sum will do the work satisfactorily. A Rolls-Royce limousine loaded with fencing wire on an outback sheep run would be an absurd situation. The British car has always held its own in its class. The British never have catered for the purchasers of purely utility cars. The policy of the British builder has always been to construct a high-grade piece of mechanism, costing more, which has found a great market in the wealthy old countries of Europe and Asia, and even America; and also to the full extent of the purchasing power in Australia. No one questions the ability of the British manufacturer to hold his own in his own class. We did not see during the war any rush on new makes of American cars in Australia. The motor traders in Australia had two alternatives—sell what they could get or close up their businesses, sack all hands, and destroy a great industry. No British or American capital is invested in the Australian motor industry. All the hard cash and hard labor in developing the trade and putting British cars on the market were all Australian. Before the war it was difficult to get prompt delivery of British goods. We don't agree that it 'is a marvel that we can make a show at all.' It is two years since the armistice was signed, and if our correspondent will examine British Board of Trade figures he will find that in most British industries pre-war figures have been exceeded. Only in the motor trade are there signs of delay in recapturing pre-war export trade, and this is due to the absorption of output in the home market."



Some importers of American cars work on big plans. This photograph indicates the extent of a "private exhibition of American cars," staged in Copenhagen by K. W. Christensen, agent there for Buick and Hupmobile cars and Denby and Clydesdale trucks. Forty vehicles were exhibited and there was music and everything to make a show attractive

Postage on Export Mail

MANY companies which have a central mailing department to handle all outgoing correspondence have found difficulty in getting the right stamps placed upon their foreign letters. In the rush of handling a large amount of mail, a foreign letter generally is included in a bunch destined for domestic points and the result is that a two-cent stamp is placed on the communication going to the Argentine or perhaps Italy. The result, of course, is generally unfortunate. The firm receiving the letter not only has to pay the missing postage and any penalties that may have accrued, but also obtains a very poor impression of the manner in which the offending company handles its foreign business.

One way of combating such mistakes is to have the word "foreign" or the letter "F" written or stamped in the upper right hand corner of the envelope where the stamp is to be placed. When the envelope is addressed, the word or letter is written either on the typewriter or pencil or a rubber stamp may be provided for this purpose. Then, when the letter goes to the mailing department to be stamped, the worker's eye is caught at once with the mark where the stamp is being placed. Thus warned, the proper stamp is affixed and the evidence of this bit of efficiency disappears with the certainty that the receiver of the letter will be unable to exclaim that "another American company has shown carelessness."

A RECENT report of the National Association of Corporation Training states that out of 117 companies from whom information was asked, 36 were making more or less extensive use of rating scales in employment and personnel work. Some twelve companies used such scales to apply to all positions; seven used them for executives only; five for salesmen; five for foremen; two for agents; three for telephone operators, and one for all employees on a salary basis.

The FORUM

Transmission Brakes

Editor AUTOMOTIVE INDUSTRIES:—It is not very often that I find myself opposed to the views expressed in an A. I. editorial, but I cannot help feeling that the recent comment on transmission brakes missed a few points of some importance.

It is my conviction that the best service brake is a transmission brake, when all things are considered, and this is not based on old European prejudice; I hope that I have very little of that left in my make up.

Taking the advantages of the service transmission brake as they appeal to the user: First, there is its great power with small exertion; second, there is extreme ease of adjustment, and third, there is much easier replacement when relining becomes necessary.

Against these unquestioned good points there are three conventional objections: That the brake is dangerously powerful, that it over-stresses the universal joints and that it puts excessive loads on the bevels in the rear axle.

Now, as a matter of fact, it is high speed rather than high unit pressure which is bad for universals, and as for the driving gear pressures, a properly designed brake does not give deceleration greatly in excess of the acceleration on low gear while the total length of time during which a transmission brake would be "hard on" never exceeds a few seconds per hour of driving.

As to the absolute power, this is a question of design. Most transmission brakes, whether American or European, are not particularly well thought out, just as most rear wheel brakes are not of the engineering quality to be expected from that of the rest of the car to which they are attached. Brake design generally has been neglected very much indeed, and has been assumed to be easy, whereas it is really not easy at all.

Many transmission brakes have been made too powerful, because, owing to the compactness of everything, very slight pedal movement is sufficient to set the brake. This can be compensated for by proper proportioning of the various levers or by the introduction of a spring link, positively limiting the pressure that can be applied to a predetermined maximum.

Incidentally the hand-operated transmission brake is far more liable to be too powerful and is far more likely to do damage owing to the facts that the leverage is very great and that the ratchet locks the brake. One of the greatest charms of a good transmission brake is its delicacy of "feel" to the foot, especially when braking on very slippery roads.

While I am altogether in accord with your editorial in its condemnation of the conventional external rear wheel brake it has a point or two in its favor which ought in fairness to be mentioned. First, if both brakes are to be rear wheel brakes, then the double expanding brakes are a little heavier. Also some brake linings are apt to glaze if not occasionally fed with abrasive material. My experience has been that linings with much brass wire are very liable to glaze if perfectly inclosed. Another drawback is that to reline an internal brake costs more than to do the same job on an external one, owing to the necessity for removing the wheels. This last argument, for whatever it is worth, must also be put in favor of making the transmission brake the service brake, if it is used at all, since a transmission brake is easier to remove and reline than any *pair* of rear wheel brakes.

There is little doubt that ideal braking is obtained from brakes on all four wheels. Properly linked, such brakes will never cause skidding and will be more powerful than even the best of transmission brakes, but the mechanical difficulties are considerable.

In the hands of the average owner or repairman the rear wheel brakes on most cars soon get a little irregular in action. The equalizing gear gums up and is never oiled and so forth. In most front wheel brakes the operating system is such that oiling and *intelligent* adjustment are essential, and the user is calling out for less parts to look after. A transmission service brake does simplify maintenance and gives better braking than the conventional system. It is also cheaper by a long shot than four wheel brakes. So, while the ideal system may have a vogue on costly chassis, everything points to the transmission brake as being the best choice for the medium priced machine. A. LUDLOW CLAYDEN.

Some Suggestions to Manufacturers

Editor AUTOMOTIVE INDUSTRIES:

Why don't more car makers install the invaluable gas saving shutters on the radiators?

Why don't they give a man who drives his own car and takes long trips in the summer, or any other time, some protection against the petty thieves who infest garages by putting locks on all door pockets?

Why don't they also protect Mr. Owner from the "smart" garage man who lifts the hood and "adjusts" the carbureter because the car won't start immediately on a cold morning, said protection to consist of good locks on the hood at a cost of $2 or $3?

Why don't they put the horn where there is some chance of a truck driver hearing it, that is, under the left headlight, so that the sound will be thrown forward without interference, and deflected to the right?

Why don't they try out some of the several hundred devices that will cause the headlights to turn with the car so that the road is always lighted even on sharp curves, at least as far as the driver can see around the "bend"? A device of this kind should, in my opinion, be non-operative in the day time, by the turning of a screw, and when in operation only the lamp on the outside of the curve should turn inward on the curve. H. C. MORRIS.

Washington, D. C.

A Book on Carburetion

WE have recently received copy of the second edition of a book entitled Carburetion in Theory and Practice by Robert W. A. Brewer, Crosby, Lockwood & Son, Publishers. New matter contained in this volume includes appendices summarizing data from papers by Professors O. C. Berry and C. E. Lucke and G. H. Baillie.

Wages and Working Hours Are Different Problems

Recent reports indicate that some manufacturers are coupling demands for wage decreases with demands for longer working hours. Fatigue cannot be swept away by fear of losing a job. Proper working hours depend upon sound investigations and analyses. They comprise an entirely different problem than that of wages and should be treated separately.

By Harry Tipper

IN the information which has been received lately concerning the notices by employers as to reduction in wages, it is interesting to note that in a number of these cases the demand is made not only for a reduction in the wages, but for an increase in the number of working hours from eight to ten, from eight to nine and from eight to twelve. This would indicate that, in the minds of many manufacturers, the present is a good time to try to bring back the conditions which existed before the war. It also indicates that in those cases the reason for the cut in wages is not entirely a case of labor surplus in their particular establishment.

There are two elements to be considered in the question of hours apart from the demand of the labor union or the worker, and entirely apart from the custom which has been established in connection with an industry.

On much of the work which is done in various lines of industry, the investigation of the medical profession and the engineers working with them have established a definite relation between the fatigue and the number of hours in each day, so that the production is not actually maintained day after day on an increased scale in proportion to the number of extra hours worked.

The question of fatigue has been occupying the attention of some of the engineers and some of the industrial medical men, but the factors which enter into this fatigue have not been established thoroughly and the results are not entirely conclusive. However, it has been observed that there is a very definite limit to the number of hours which can be worked economically on any given class of work, and these limits vary according to the condition and character of the work.

There is, of course, a considerable variance in the actual fatigue established in the individual case and it is necessary to secure an average from a number of cases in order to determine the general conditions governing that kind of work.

Previous custom is not of much importance in this respect, as the earlier investigation did not deal with the human side particularly, and the knowledge of the human frame had not reached the point where we could determine fatigue with any reasonable exactness or know anything about the factors which enter into it. The bibliography of production is very barren of information on this subject, and it is necessary to go to the medical library to get the best work which has been done upon this matter.

Nevertheless, sufficient has been accomplished to show that the fatigue established by the working period bears a direct relation to the length of the period, and when it is accumulated to a certain degree, it has a tendency to carry over so that the efficiency is not as great at the start of the following day. This, of course, is particularly true in the highly repetitive, monotonous work which requires concentrated effort of mind and hand upon a few rapid operations, but it is true of all classes of work, although the length of the required period varies.

The extension of a half hour in the working period is sufficient to accelerate the production drop very rapidly in the extended period, and it is a question whether the production increase secured in the period of extension is sufficient to justify the operation being continued that length of time.

These manufacturers who are demanding a return to the ten and twelve-hour day without having considered the matter apparently any further than their desire to establish pre-war conditions, are forgetting the fact that the cost of production is a relation between the cost per hour and the production during the same period.

The idleness of machinery frequently costs a great deal more than the idleness of men, and it is better to close down the establishment rather than to run the machinery at a production which is not sufficient to pay the interest charges on the machinery operation.

This is not an absurd picture, as investigations have shown in past years similar conditions existing in industries where long hours have prevailed, without regard to the character of the work and the extent of the fatigue established during the working period.

Sufficient attention has not been paid to the investigation of production curves and the effect upon these of a small decrease or increase in the working period itself. And practically no investigation has been made as to the effect of a long working period, day in or day out, upon the attitude of the worker, his incentive, and the demand for the establishment of a minimum pace. The object, of course, of all operations in industry is to establish the minimum cost per piece in production, and this object is not always to be determined by a calculation of the rate, the hours of work and the average work per hour. There is too much difference in the capacity of the man and the amount of work he is supposed to do

under conditions which do not tend to bring out the full potential power.

It is not so long ago that several industries changing from nine to eight hours found production per man to be the same for the shorter day, and it is interesting to note, that with the new arrangement between the British coal miners and the government, although the hours have been materially shortened, the miners are showing the increase which will justify the wage increase.

It may be that industry will find that a greater number of shifts at maximum capacity with the same machinery will permit of a better production ratio cost than the present method. At any rate, the subject of the hours of labor economically of most value is too much a matter of investigation, analysis and consideration of the medical and industrial factors involved to make it a matter of argument with the workers because the manufacturer happens to have the advantage for the moment.

The question of wage reductions is one thing; if the cost of the articles themselves will not justify the wages that are being paid, it is necessary that those wages should be reduced. The question of hours is an entirely different matter. This is not merely a matter of extending the amount of production. It might be of no value to the manufacturer who paid hourly wages. The only advantage will be in the case of the manufacturer who pays by the day and who hopes to secure a sufficient amount of extra production in the hour or two hours demanded, to pay for the running of the plant during the extra period.

The circumstances under which these demands have been made do not indicate that the manufacturers' investigations have clearly demonstrated the length of working period which would be economically sound for his factory, and it is unlikely that any such investigations have been made as they are unusual and most factories have not attempted to examine the question from this standpoint.

Fatigue is not something which cannot be overcome by fear of the job and it is not swept away simply because the conditions are to the advantage of the employer. It is definitely related to the effort in character and extent, and the length of the period through which that effort must be made. It is just as definite in its consequences, and while it depends to some extent upon mental factors, the result is physical and finds its expression in a decrease or limitation of production.

It is not a question of labor politics or the demands of labor, but it is a question entirely of sound economics and the best economy to the manufacturer. The reason it has had so little attention is that the average manufacturer has not studied the investigations which have been made and the average engineer has not had the opportunity to go into it as it affects the production of the plant.

These changes which are suggested in various localities in accordance with information received, may or may not be justified, but their wisdom is not indicated by the circumstances and it is a mistake to tie up a demand for longer hours with a wage reduction at the present moment. The two things should be treated as different matters and approached in different ways.

Touching Bottom in Seeking a Basis for Wage Payments

WITH numerous factory representatives gathered in one place, it was possible during the New York show to ascertain with some degree of accuracy the general action being taken concerning wages in the industry.

An examination of reports from twenty-two representative automobile concerns, published in a recent number of AUTOMOTIVE INDUSTRIES, shows that eleven of these firms have reduced wages and that eleven of them have not reduced wages up to the present time.

The wisdom of reducing or failing to reduce wages just at this time cannot be finally determined as yet. The real test of the judgment displayed will come later when production is normal and good workmen are in demand. It will be very interesting to the student of industrial affairs to note the production and labor turnover results obtained by the different firms at that time, and in the light of those facts to interpret the wisdom of cutting or failing to cut wages at this time.

There is no disputing the fact, of course, that wages will inevitably fall with the cost of living, but there is some question as to whether they should follow or precede a definite change in that respect. Food and lodging are the two largest items of expense in most families, and while the former has dropped somewhat, there has been no change for the better in the latter. And with rent costing many one-fourth to one-third of earnings, it must be counted as a large factor in living expense.

Wages took a tremendous jump during and after the war, but so did the cost of living, and wages followed the cost of living up—they did not precede it. Moreover, in discussing the present wage situation, it is not feasible to lay undue emphasis upon the percentage of rise in wages since 1914. Before the percentage of rise means anything, it must be established that the relation between wages and the cost of living was a just one in 1914. Undoubtedly it was not in very many cases.

If a certain class of workman was receiving in 1914 much less than was just, he cannot in fairness be expected to justify a decrease now because he has experienced a rise of 100 per cent since 1914. It is manifestly absurd to argue the question of fair wages upon the basis of how much wages have increased since before the war, because it is by no means established that the wage basis at that time was fair.

The difficulty with wage arguments and adjustments lies in the fact that they are placed upon an unsound and unscientific basis. Never in the history of industry have wages been determined upon a fundamentally sound basis; and they never can be until the various factors, human as well as mechanical, which are involved are more thoroughly studied, investigated and understood.

"Until we are willing to take production service as a basis of reward and to analyze that service so that it can be determined in its individual relations," wrote Harry Tipper recently, "wage systems must continue to be arbitrary and in themselves ineffectual in inducing the worker to put forth his full effort in production, incapable of removing the conflict which exists at all times, and insufficient to provide a reasonable measure of justice for all workers.

"Of all the systems for general wage payments being used at the present time the ones which are predicated upon the relation between the individual and the quantity and quality of his production, are the most effective in their general application."

Why Not a Competitive Fuel Economy Test?

THERE are indications that a well-organized road test in which suitable prizes would be awarded for the cars that make the greatest mileage per gallon of fuel would attract many entrants and wide engineering as well as popular interest. Such a test would, of course, have to be run under carefully drawn rules which would take into consideration the size and load of the car, and would, to be of greatest value, have to be run under careful supervision to prevent freak methods of driving which no one would consider following in the normal use of a car.

Some manufacturers, especially those who build cars with air-cooled engines, consider that they are in a class by themselves when it comes to getting maximum fuel economy, but there seems to be little doubt but that a well-designed water-cooled car of equal weight could equal if not surpass the performance of the air-cooled car, for it should be able to operate with higher compression ratio, and perhaps a better load factor than the other type, while with proper control of water temperature the cylinder walls need not be unduly cool.

However this may be, under intelligent rules there is opportunity for a competition that would prove instructive, and, we believe, thoroughly worth while. Such tests at least bring out possibilities or establish marks at which to aim in commercial practice. Whatever their advertising value might be it would be of small moment as compared to the engineering stimulus that should result.

We shall be glad to hear from engineers as well as manufacturers who would be interested in or lend their support to such a competition. Comments as to the rules which should govern an event of this character will also be welcomed.

The Chicago Show

THE increased buying which the opening day of the Chicago automobile show made evident is but a concrete expression of improved sales conditions that began evidencing themselves soon after Jan. 1 and are continuing. In former years the increased wave of buying set in motion by the show continued into the spring and summer selling season with increased momentum but there should be careful watching of the show stimulation this year. In two cities, Los Angeles and New Orleans, the show stimulation failed to continue as formerly. Following the New York show, the Gotham dealers have experienced increased sales and manufacturers will do well to follow closely each week the influence of the Chicago show. It yet remains to be definitely established whether or not the wave of sales due to the shows will grow into an appreciably increased volume of business. It should not be taken as an established fact that such will necessarily follow.

The show circuit so far—and reports from distributers from the country—establish the fact that there are two classes of interested visitors:

> FIRST, those that have money but are carefully conserving it and are intelligently studying general conditions. SECOND, those that are temporarily embarrassed due to lack of employment or shrinkage of resources and looking for future information.

It is the lower-priced cars that are most affected by the lack of buying capital. It is in this class that reduced production will be noticed during this year.

Among distributers there are wide differences of opinion regarding price changes. The policy to be pursued is largely individual with different organizations. Several companies, that have made substantial reductions in the past four months and are giving rock bottom values, are not only going steadily on with a manufacturing program but the cars are selling generally. The public seems to be conscious that they are giving good value for the money. Others cannot make price alterations, due to stocks in dealers' hands and heavy inventories. There are sections of the country where the scarcity of money is such that any price reduction would not stimulate

sales because, despite the reduction, the money scarcity would prevent buying.

The Ford situation is creating much discussion and a good deal of confidence is given to the opinion that Ford will have to increase his price or resume production on a 100 per cent basis, and that an increase in Ford price would have a very stabilizing influence on the industry, proving to the doubting Thomases that the bottom has been reached on a number of cars. With so many out of the buying market in the low price field, a resumption of 100 per cent production seems improbable.

The Chicago show is offering the greatest opportunity for studying conditions, but the study will have to be continued for weeks after the show is over. Most manufacturers are going to resume production on one scale or another as a result of the Chicago show and are not placing much importance on such local shows such as those in Minneapolis or Kansas City.

A Factory Service Manager's Task

THE recent meetings of the factory service managers have brought out one point that should make for better service for automobiles in the future. An increasing number of factory service managers are listing for their several service stations the tools that can best be used for repairs on the car with which they are chiefly concerned. In many cases it is necessary for the service manager to design and practically manufacture certain tools so that his car can be serviced at a cost comparable with the service of competing cars. Recently Paul Williams, service manager of the H. H. Franklin Mfg. Co., classified the tools that must be listed as follows:

1—Commercial wrenches (this includes such wrenches as standard open end and pipe wrenches).

2—Specialty tools. These are made by companies making special automobile tool equipment; such as valve grinders, etc.

3—Tools required for the particular make of car the distributer is handling.

If service managers generally would interest themselves to this extent in their service stations, service would begin to look up. It is especially the task of the factory to see that the local service man knows how he can most economically do the work brought to him by the owner.

Thrift Campaigns in Factories

A CAMPAIGN is being carried on to induce manufacturers to institute thrift departments in their factories. In the main, the suggestion is that Liberty Bond campaigns be repeated. It has been suggested to AUTOMOTIVE INDUSTRIES that we endeavor to persuade different automotive factories to enter into a competition to determine which can sell the largest proportion of securities to employees.

But we are not ready to do this. The disappointments of the Liberty Bond campaigns are many. The chief consolation is that it was a patriotic effort. Whatever the results, they were justified by the emergency. The bitter taste is due to the market price of Liberty Bonds since they were sold. Imagine what the impression would be if a campaign was waged in a less worthy cause. Some companies that last winter sold heavily of their own stock to employees on part-payment plans have had a serious time in explaining what has happened, especially when it was necessary to lay off or discharge the purchaser.

But we believe in teaching thrift to workers. It would be a very fine thing if every worker owned some securities, or had other negotiable wealth. You all are familiar with the arguments and there is no use repeating them. We think the idea of inculcating thrift is a splendid one, but we would proceed on low gear.

One man who is prominent in this campaign has stated his reasons for favoring such a campaign very differently from the usual thrift promoter. He says that industry to-day needs much money and that, because of the surtaxes on incomes, this money is not going to be forthcoming from its usual sources—the monied men and women of the country. Therefore, we must find new sources of wealth. The small saver is next on his list. So he suggests that each manufacturer would only be helping himself by inducing his employees to buy.

Very good. But can you assure yourself to-day of an investment that will remain of sufficient value for you to recommend it to the small and more or less uninformed purchaser? It might be well for manufacturers to teach thrift and to encourage savings, but he should be very careful what securities he recommends. Perhaps the establishment of a thrift office, where individuals will be advised as to possible investments, would be best under the circumstances.

The project is a very commendable one if it is carried forward with sufficient caution.

Bankers Recognize the Automobile as a Necessity

IT is interesting to note the worth while comments of bankers concerning the automotive industry, now that they are taking an active part in the financing of our operations. George C. Roberts, the eminent banker who spoke at the Society of Automotive Engineers' dinner during the annual meeting, discussed the "necessity of automobiles" in one sentence. He said, in effect: "The automobile has proven that it is a necessity because no man who has owned one will now be without a car." Slowly the men who have power in financial circles are putting themselves on record in favorable opinions.

A STRONG appeal is being made by the National Foreign Trade Council to members of Congress not to reduce the appropriations for the promotion of foreign trade. The automotive industry should be sympathetic with this promotion. O. K. Davis, secretary of the National Foreign Trade Council, 1 Hanover Square, New York City, can tell those interested how they can best assist.

1920 Exports Double Former Year

Gain of $154,000,000 Largest in Industry

Trade Balance Immensely Favorable to Country—Returned Vehicles Total $11,511,995

WASHINGTON, Jan. 31—Analysis of statistics prepared by the Bureau of Foreign and Domestic Commerce to-day shows that 1920 was the greatest year in the history of foreign trade in automotive products. Exports of automobiles, trucks and automobile parts more than doubled in value in the twelve months period ending Dec. 31, 1920. Sales of passenger cars on foreign markets increased by $91,555,394, the total value of the 142,508 cars being $165,255,921. The 29,126 trucks shipped abroad last year represented a value of $46,765,781 or an increase of 13,641 trucks in excess of 1919 shipments and an increased value of $11,340,344. Imports of 926 cars were valued at $1,026,518, an increase in quantity of 809 cars and $903,493 in value.

There were but two instances where automotive products declined in volume or value. Shipment of airplane parts fell from $3,249,226 to $554,375, notwithstanding the fact that exports of airplanes doubled in value. Sixty-five planes sold overseas last year were valued at $598,274 as against 44 machines with a declared valuation of $215,300 in the preceding year. A slight drop in the volume of marine gas engines was reported, exports for 1920 amounted to 9616 engines valued at $3,283,341 as compared with 10,485 engines valued at $4,363,538 in 1919.

The official figures make clear the fact that the American automobile manufacturers are effectively cultivating foreign markets for their products and the steady and marked gains in this direction indicate that the domestic depression is but momentary.

Import Business Prosperous

There are unmistakable signs that foreign manufacturers have enjoyed a prosperous trade in this country during the past year. The resumption of automotive manufacturing abroad and the careful cultivation of the American market made but little difference in the consumption of American products. The combined exports of automotive products represent a gain of approximately $154,000,000. Imports of automobile parts other than tires for 1920 amounted to $1,252,250 as compared with $278,003 last year, an increase of $974,243. The total imports of automobile and automotive parts were valued at $1,877,736 or a small percentage of the exports.

The year of 1920 witnessed the return in large volume of American cars and trucks to point of manufacture. The records show that 4959 vehicles with a valuation of $7,921,540 re-entered the country without an assessment of duty. This amount is nearly double the value of cars returned in 1919 when 1656 machines carried a valuation of $3,590,455. The business of returning cars to this country fell off in December, 1920, for there were only 42 automobiles valued at $66,041 returned free as compared with 159 cars valued at $390,780 in the same month in 1919.

J. Allen Smith Heads New Car Corporation

SYRACUSE, Jan. 31—The Nera Car Corp. is under process of organization here. It will be headed by J. Allen Smith who recently resigned as president of the New Process Gear Corp. and the United States Light & Heat Co. and as vice-president of the Willys corporation. He will be associated with Carl Neracher who also has held an important position with the New Process Gear Corp. Smith will be succeeded at the New Process Gear Corp. works by Layton R. Burt of Rochester.

Plans for the Nera car which the new company proposes to construct in this city, have not been announced, but it is understood it will be a vehicle especially designed for commercial work and will be ready for the market some time in the next six months. Neracher is the originator of the vehicle which is not entirely unlike an English invention largely used abroad.

Special virtues claimed for it are its exceptionally light weight and economy of operation. The promoters believe it will supplant many of the lighter delivery trucks now in use. Those who have seen the Nera car say that it is a cross between a motorcycle and an automobile and that it will not weigh more than 200 or 300 lbs. It will be capable of a speed of 30 miles an hour.

STEEL PRICES UNCERTAIN

YOUNGSTOWN, OHIO, Jan. 29—Steel prices and steel plant wage rates are still very much unsettled and uncertain. Officials of the larger independents and of the steel corporation properties are unable to forecast conditions in the valley, although there is no note of pessimism. New business is not in the volume that has been confidently expected, however.

BIG MARKET SEEN IN CHINA

BOSTON, Jan. 31—There is a big field for the sale of motor vehicles in China, according to Prof. Marshall L. Perrin of Boston University who has recently returned from a tour of that country.

Propose to Dump 5000 Trucks Here

Slough Company Finds No Market in England for U. S. Used Army Trucks

LONDON, Jan. 21—(*Special Correspondence*)—The Slough Trading Co., headed by Sir Percival Perry, former Ford manager in England, expects to sell in the United States a very large number of rebuilt army trucks and passenger cars, which were manufactured in the United States, and which were bought up at a ridiculously low price. It is understood that at the beginning of the year the company had on hand 10,000 of these vehicles and it hopes to dispose of approximately 5000 trucks in America. Many of the trucks are Packards and Rikers, but the majority were made in the Peerless factory for the British government during the war.

The Slough company's stock is going very slowly in this country as there is practically no demand at this time. As evidence of this situation, it is current gossip that if a man goes down to Slough with 100 pounds sterling in real money in his pocket, the gates are locked and he is not allowed to go out until he has bought something, and that something is quite likely to be a rebuilt 3-ton truck or a rebuilt passenger car.

The company has sent rebuilt trucks, as samples of what can be done, to all the Colonies and initial shipments have been sent to the United States to test out the market there. The lines which are going to America are those which are not well known over here or in the Colonies. The present premium on the dollar makes American business specially profitable at this time and it will be possible for the Slough company to undersell American makers and even used vehicle dealers in their own market.

Congressmen Getting Protests of Dealers

WASHINGTON, Jan. 31—Careful investigation here discloses that under the present law there is nothing which can be done to prevent the dumping on the American market of army trucks made in America and purchased in England by the Slough Trading Co. at a very low price. As a matter of fact, the British traders are not even compelled to pay import duty for the law provides that goods made in this country can be returned without any tariff charges.

The first shipment of these trucks to the United States was dumped on the

(*Continued on page 246*)

Baker Orders Army Truck Inquiry

Problem of Surplus to Be Determined

Anthony Presents Legislation to Dump Excess Vehicles— Reaves Urges Road Need

WASHINGTON, Jan. 31—Congressman Anthony's persistent efforts to dump 10,000 Army trucks on the market as surplus property and the introduction of measures requiring the transfer of this property to the Bureau of Roads for highway construction brought about a crisis in various branches of the Government to-day which resulted in a formal order from Secretary of War Baker directing the Inspector-General of the Army to conduct a thorough inquiry. There is some question as to the time required in the investigation but it is understood that the incoming Secretary of War will continue and possibly broaden the activities of the Inspector-General to a general inventory in order that the controversy may be definitely settled.

The Army appropriation bill which Congressman Anthony reported out to the House Saturday as chairman of the sub-committee on appropriations, carried legislation which "the committee has found necessary in order to carry out its policy of forcing an economic and efficient administration of the War Department, to freely resort to the use of limitations upon various funds, and in some instances in order to compel the sale of certain unnecessary supplies."

The chairman advised AUTOMOTIVE INDUSTRIES that this proviso was inserted to compel the War Department to declare 10,000 trucks as "surplus" and sell them. He stated that inquiry convinced him that the Bureau of Roads had sufficient trucks and motorized equipment and could not absorb the surplus material of the War Department.

Would Limit Motorized Units

The legislation which the Anthony committee introduced would limit the War Department in issuance of motorized equipment to National Guard organizations, contending that the infantry units should be developed and "minimize the organization of those branches of the guard which require the issue and maintenance of animals and motors and special technical equipment." The grand total of the Army bill providing for the support of the organization is $331,222,612.12 or $63,477,965.08 less than current appropriations and $368,052,890.31 under the departmental estimates.

It is quite possible that this proposed legislation which the Kansas congressman intends to push through the House will be blocked on the ground that it is new legislation and not authorized by law. The attachment of these "riders" to appropriation measures is one of the principal causes of filibusters which delay essential money bills.

The fact that the passage of the Anthony measures would defeat the purposes of the Reavis bill introduced in the House last week indicates that a strong fight will be made to block the "rider." Congressman Reavis introduced a bill at the last session which would require the War Department to transfer surplus motor equipment to the Bureau of Roads but it met with a pocket veto. A similar measure was presented by him last week. National organizations of highway officials are in favor of the Reavis bill which would allow the various States to obtain trucks, tractors and other machinery at small cost. It would also prevent dumping this used equipment on the present overstocked market.

Both Reavis and Anthony claim that this equipment is rotting at camps here and abroad. The Inspector General must submit a report on three charges. He is also directed to inquire into allegations as to disposal of equipment through the sales department of the Surplus Property division.

R. C. Durant Joins New Durant Motors

NEW YORK, Feb. 1—R. C. (Cliff) Durant, son of W. C. Durant, will have charge of the distribution on the Pacific coast of the cars which will be manufactured by Durant Motors, Inc. He will also be in charge of an assembling plant which ultimately will be erected at Oakland.

As soon as his father announced the formation of the company which he will head, the younger Durant resigned as vice-president of the Chevrolet Motor Co. of California. With him will be C. M. Steves who has been Durant's assistant for several years in active charge of the Oakland Chevrolet assembling plant. Both men will give all their time to the new organization.

JEFFERSON PRODUCTION NEAR

JEFFERSON, WIS., Jan. 31—The Jefferson Rubber Co., which is erecting a new tire and rubber goods manufacturing plant at Jefferson, Wis., to be ready for production about Feb. 15, has made a return gift of $15,000 in cash to the Jefferson Realty Co., which provided a bonus of $25,000 four months ago to secure the industry for the city. The new factory is 80 x 300 feet in size and now fully enclosed, so that interior work is under way and some equipment is already being installed.

Limited Production Proposed by Ford

Not More Than 5,000 Men at Work—Few Cars to Be Made in February

DETROIT, Jan. 31—Approximately 5000 men returned to work to-day at the Highland Park plant of the Ford Motor Co. Virtually all of them are engaged in getting the plant ready for production, but the manufacture of cars has not been resumed and it is impossible to learn when it will be. The force will be increased gradually and when production is begun, it will be on the basis of actual sales and it will be some time before anything like a real working force is employed or quantity production started. It is safe to say that comparatively few cars will be made in February.

None of the parts makers who supply Ford have been given opening orders save the Briggs Mfg. Co. which makes coupe bodies. That company has recalled about 1000 men or 40% of its normal force on the strength of instructions from Ford, but it is said the order does not specify the number of bodies Ford will want or when his production will begin.

The parts manufacturers are under the impression that the probable production in the Ford factory for February will not be large enough to warrant them in reopening their plants. The Fisher Body Co. is taking on a few men each day on account of the gradual improvement in business.

The Liberty Starter Co., which makes all the Ford starters except those manufactured in the Ford factory, has not been ordered to resume operations. Officials of the company say they have no surplus and expect to receive instructions to start as soon as Ford production begins.

Formal Statements Withheld

It still is impossible to obtain any authoritative statement covering the Ford situation. Edsel Ford has not been discharged from the hospital where he recently was operated on for appendicitis and so many of the officials of the company have resigned, that those who are left are not taking any chances of unpleasant consequences by discussing the present situation. Nothing definite is known here of the progress of the negotiations for a large loan. It is understood that representatives of the Guaranty Trust Company, The Chase National Bank and the Liberty National Bank, all of New York, are participating in the financial parley. Bankers here are skep-

Many Bankers Attend Chicago Show Meet

Inspiring Addresses Feature Big Dealer Event—Urge Conservatism in Methods

CHICAGO, Feb. 1—Courage and clear headedness were held up as qualities necessary to carry on through the present business situation by speakers at a rousing trade rally with which the Chicago Automobile Trade Association, the National Automobile Chamber of Commerce and the Motor & Accessory Manufacturers Association opened the week's activities. Twelve hundred and twenty-five men, distributers, dealers and salesmen from Illinois and surrounding States, and manufacturers from all parts of the country, attended the dinner, which was alive with enthusiasm and which got everybody set for a week of hard work at the show.

Presided over by Leo A. Peil, president of the Chicago association, the program presented to the big crowd included George M. Graham, vice-president of the Pierce-Arrow Motor Car Co.; H. H. Merrick, president of the Great Lakes Trust Co., and A. R. Kroh, who has spoken at hundreds of farmers' and business men's meetings throughout the country. Significant in the attendance was the presence of a large number of Chicago and Central Western bankers, who rubbed elbows with the automobile men and heard Graham's address on the essential place of the automotive industry in the development of the country.

Graham cited history to prove the stability of the country and to show the soundness of investments in its future. He said that business had been running on too rich a mixture.

Graham defended the sales departments against critics of their methods during the period of easy selling, declaring that they never ceased fighting for business for their companies, no matter how easy orders came.

Merrick bespoke the faith of bankers in the automotive industry and urged upon it courage, conservatism and balance as sure builders of the road to success.

Kroh presented his picture of the benefits to accrue to industry and commerce from the improvement of farm conditions possible through diversification of crops and use of labor and time saving machinery.

Easier Credits Help Ohio Trade Recovery

TOLEDO, Jan. 31—The number of unemployed here is gradually growing smaller because of increased industrial activity in Toledo manufacturing plants. The improved situation and the stimulation given by the automobile show are helping sales of motor cars. Dealers are making some sales for immediate delivery and more for April delivery in the city and though dealers in the outlying territory are taking only a few cars at a time, they are not standing still.

Credit and used cars remain the big obstacles to sales all through the territory, as elsewhere in Ohio. There is no more bank discrimination against the industry but financial houses simply haven't the money to loan on account of their investments in frozen industrial and agricultural inventories. Acceptance corporation rates are so high dealers and customers are protesting. However, the bank situation is better, with factories getting into production again and with farmers, on the eve of the planting season, letting go some of the crops that they were holding for higher prices.

United States Leads in Trailer Industry

WASHINGTON, Jan. 31—American consuls in all parts of the world have reported to the State Department on the possible market for motor truck trailers manufactured in the United States. These reports show that this country is far in advance of all other countries in the use of this economical aid to highway transportation, notwithstanding England was first to adopt the principle of trailer transportation and there are about a score of trailer manufacturers in Europe, located in England, France, Italy and Germany.

The United States, with about 75 trailer makers and probably 50,000 trailers in use, leads the world in this new industry. Trailers are being exported in limited numbers from this country to many parts of the world, including Canada, the West Indies, some South American countries, England, Scandinavia, West and South Africa, the Philippines and even China.

KALAMAZOO NAMES OFFICERS

KALAMAZOO, MICH., Jan. 31.—The Kalamazoo Motors Corp. at its annual meeting in this city re-elected H. A. Crawford president, and Joseph E. Brown of Kalamazoo to succeed William Johnson of Sioux Falls, S. D., as vice-president. R. M. Gregory and W. B. Milham continue respectively in the offices of secretary and treasurer. Two changes are reported in the board of directors, B. A. Bush and Glenn L. Shipman succeeding Frank H. Milham and A. L. Pratt.

ENGINEERS ESTABLISH PRIZE

NEW YORK, Jan. 31—The American Society of Civil Engineers has accepted the offer of the Engineering News-Record to establish an Arthur M. Wellington prize to be awarded annually for the best paper presented before the society on any phase on the science and art of transportation, whether by land, water or air. The prize is a memorial in honor of the former editor of Engineering News and consists of the income from a fund of $2000.

Metropolitan Sales Doubled in January

Steady Upward Trend Experienced Following Show—Look for Normal Spring

NEW YORK, Jan. 31—January showed a slow, steady upward bending of the sales curve in the Metropolitan district. With motor car sales showing a gain over December of 50 to 100 per cent, territorial distributers are convinced that they have "turned the corner" and that there will be a gradual resumption of buying to a point probably within 50 per cent of last year's abnormal figure.

Nobody is making extravagant claims for spring. They realize that the January sales record contains the New York show impetus, and that the succeeding months will have to stand on their own legs, aided slightly, perhaps by the closing of show prospects.

New York's greatest encouragement is the optimistic reports from the smaller dealers of the territory. Wholesale orders were particularly good following the show and the weekly reports of sales indicate a decided weakening in the buying apathy in the territory. Aggressive selling of the past two months is having its effect.

Truck distributers feel somewhat encouraged, but have experienced very little increased trade. The truck business is described as "spotty" which is taken to indicate that it is reacting to the resumption of business in various industrial lines.

With the settling of the weather and the beginning of building operations, which are expected to open on a fairly large scale, a decided increase in the sale of trucks is expected.

The weather and the resumption of spring business is also a factor in the consideration of spring business by the passenger car dealers. It is felt now pretty generally that the breaking of the mild winter to date by a heavy storm or two may postpone the actual opening of spring buying a week or two, but it is too late in the season to have any effect for a longer period.

WILSON LISTS NEW OFFICERS

PONTIAC, MICH., Jan. 29—There have been several changes among the officers of the Wilson Foundry & Machine Co. for which reason a list of officers and directors to date has just been issued. The officers are: President, Charles B. Wilson; vice-president and general manager, D. R. Wilson; secretary, W. E. MacKenzie; treasurer, C. E. Killinger; assistant treasurer, Dave J. Moreland. Directors: Walter C. Chrysler, F. K. Dolbeer, C. B. Wilson, G. R. Spencer, D. R. Wilson, C. E. Killinger and J. E. Kipperley. Officials express confidence as to the future and believe that before the end of February the big plant will again be in big production.

Chain Company Sues to Protect Patent

Infringement of Weed Rights Alleged in Suit Against Philadelphia Companies

WILMINGTON, DEL., Feb. 1—Suit has been started in the United States District Court here by the American Chain Co., Inc., against the United Auto Stores, Inc., of Delaware, and against George J. Campbell for infringement of the Weed chain patent No. 768,495, granted Aug. 23, 1904. Both defendants have their principal places of business in Philadelphia. A motion for preliminary injunction has been set for hearing before Judge Morris on Feb. 14.

It is alleged in the complaint that a chain of the so-called reversible ladder type was manufactured by Campbell so that it closely resembled in construction and general appearance the genuine Weed grip, but containing inferior quality material and workmanship. These chains were sold by the United Auto Stores. Except for the acts of the defendants, it is declared there has been general acquiescence on the part of the public in the rights of the American Chain Co. under the Weed patent.

It is further alleged that the defendants are engaged in unfair competition in that the chain grips made by Campbell and sold by the United Auto Stores are provided with cross-chains having a light coating of copper plating which contrasts with the gray coating of the side chains, giving these chains an appearance decidedly similar to the distinctive dress that has long been given to the Weed grip by the American Chain Co.

Parsons Patent Expired

NEW YORK, Feb. 1—Life of the patent granted Harry Parsons, known technically as No. 723,299, under which the Weed tire chains had been made for seventeen years, expired March 24, 1920. This was controlled by the American Chain Co., which succeeded the Weed Tire Chain Co., and purchased the Weed holdings. The company also owns the Weed patent No. 768,495. The Parsons patent covered a chain put on zig-zag fashion, and the Weed a chain which goes straight across the tire.

GRAND RAPIDS PLANTS RESUME

GRAND RAPIDS, MICH., Jan. 31—The The Hayes-Ionia plant has taken back 500 men and will be back to normal Feb. 15. Three hundred employees will return to the Macey company's plant Monday.

CORRECTION

An error was made in the issue of AUTOMOTIVE INDUSTRIES of Jan. 20 in its account of the decision of the United States Supreme Court sustaining the right of revenue officers to seize any automobile containing contraband liquor regardless of whether the owner had knowledge of the illicit use to which the vehicle was being put. The article stated that the particular car in question was loaned to a friend. This was an error because the car had been sold to J. W. Goldsmith by the Grant company although only $800 had been paid on it and the Grant company retained title as the actual owner. The Grant company had no knowledge whatever of the transportation of liquor in the car but the vehicle was ordered forfeited.

Diamond T Restrains Cut-price Advertising

ST. LOUIS, Jan. 31—A perpetual injunction has been granted in Federal court by Judge Faris to the Diamond T Motor Car Co. of Chicago, restraining Harry Newman, Inc., of this city, from advertising or offering for sale Diamond T trucks at less than their listed price. In the petition for an injunction, it was alleged that the defendants were former distributers of the truck in St. Louis but that their contract was cancelled for good reason and that they were advertising in twenty-five of the larger cities of the country that they would sell Diamond T trucks at a 35 per cent discount without any intention of makng bonafide sales, but with the malicious purpose of injuring the motor car company and for the further purpose of forcing the settlement of a law suit then pending.

Judge Faris appointed a special master to establish damages and in granting the injunction, declared he never had seen a case "that equals the malice involved in this."

BADGER INCREASES CAPACITY

MILWAUKEE, Jan. 31—The Badger Mfg. Corp. of Milwaukee, maker of bumpers, tire carriers, racks, creepers, cutouts, steering wheels, etc., has moved into quarters where 45,000 sq. ft. are available, as against 26,000 sq. ft. in the former plant at 313-315 Milwaukee Street. The new factory is one erected several years and until now occupied by the Harley-Davidson Motor Co. as its automatic screw machine shop. The Badger Corp. was formed in 1917 as the outgrowth of the Auto Parts Mfg. Co., organized in 1914. It is capitalized at $300,000 and is increasing its force from 150 to 200 men. The business of 1920 aggregated nearly $1,000,000, against $601,000 in 1919. Charles H. Hathaway is president; John T. Johnston, vice-president, and Walter V. Isgrig, secretary and treasurer.

OILGEAR TO MAKE PARTS

MILWAUKEE, Jan. 31—A charter has been granted to the Oilgear Co., incorporated under the laws of Wisconsin with $500,000 capital stock, to engage in the manufacture of hydraulic transmissions and devices for the automotive and general industries. The promoters are represented by J. A. Dietrich, Howard T. Foulkes and J. A. Wickham, of the law firm of Quarles, Spence & Quarles.

Interlocking Tire Officials Resign

Complete Re-organization of the Company Is Planned by Stockholders and Creditors

AKRON, Jan. 31—Creditors and stockholders of the Interlocking Cord Tire Co. of Akron and Mogadore will completely reorganize the company and name new officers to replace present directors and four of the main officers who are under criminal indictment for alleged violation of the Ohio "blue sky" law. Announcement to this effect was made following the formal offer of Walter Kline, president; C. E. Foust, secretary; J. W. Rinear, treasurer, and L. W. Rinear, sales manager, to resign as officers of the company in order to permit lifting of the temporary receivership under which the corporation now is operating. Kline and his co-officers made the offer of resignation before Judge Willard Wright in Common Pleas Court to-day.

Kline is indicted for alleged violation of the "blue sky" law and on a charge of obtaining money under false pretenses. Foust and the two Rinears are indicted under the "blue sky" law for alleged assistance in flotation of the corporation's securities without a State license.

Following the offer of resignation, thirty-six creditors of the company, whose claims constitute approximately $75,000, met and agreed tentatively to accept the offer and to proceed at once with the reorganization of the company. F. B. Hood, Arthur Sweeny, Frank Lea and W. B. Smith, who were recently elected to the directorate of the Interlocking Cord Tire Co., but who have not as yet qualified for such official capacity, have also offered to resign, it was announced.

Creditors named a committee consisting of W. H. Flower, chairman, F. J. Bents, L. E. Newman, Otis Prier, R. B. Koontz and P. E. Welton to confer with stockholders on the matter of reorganization. A meeting of stockholders will be called, it was announced, to consider the proposal and ratify the plans and also to select representatives on the new board of directors.

Officers Deny Allegations

Indicted officers of the company have issued sweeping denials of all charges contained in the receivership and the criminal indictments. In a formal statement they charge the receivership and grand jury actions to be the result of an alleged attempt upon the part of a few stockholders to form a conspiracy to "ruin the company," and that the indictments were sought "simply to scare more stockholders into the opposition camp," it being stated by the officials that stockholders originally petitioning for the receivership never at any time represented more than 10 per cent of all shareholders.

Burleson Defends Junker Plane Use

General Efficiency and Economy Factor in Purchase—American Craft Little Used

WASHINGTON, Jan. 29—Responding to a House resolution demanding information relating to purchases of Junker aircraft, Postmaster-General Burleson to-day advised the Congress that Junker planes have demonstrated their efficiency and economy in actual demonstrations.

The Postmaster-General said:

"The Junker airplanes purchased by the Post Office Department represent a forward step in airplane development over the development at that time in this country. Their operation over 30,122 miles gives 5.1 miles per gallon of fuel, as against an average of about 2.5 miles per gallon with the planes and motors in the air mail service. The cost of flying operations with these planes is about 30 per cent less and the cost of maintenance and upkeep about 50 per cent less than is the flying cost and maintenance cost of the Liberty motored De Haviland planes turned over to the Post Office Department by the Army and Navy.

"On the other hand, the cruising radius of the Junker plane is at least 50 per cent more and the possible mail load is nearly two and one-half times as great as that of the surplus war planes with which the air mail is principally operated. Whether the relatively low cost of maintenance of a Junker plane over a De Haviland will continue as the planes see more service is something that is being determined by the daily operation of these planes by the side of the De Havilands.

"When the German planes were put into service by the Post Office Department, after planes of this type had made a number of remarkable long-distance runs for other parties, defects in the fuel installation and in the engine compartment, ventilation and drainage were discovered through planes catching fire in the air.

Construction Defects Corrected

"These defects of construction and engineering were promptly remedied by the Post Office Department, since which time the planes have been operating steadily in the mail service without fire hazard or casualty of any character to the crews operating them. The safeguarding against fire hazard, as the result of the accidents to the Junker planes, has been of great importance to aviation and has resulted in the elimination of fire hazard in other mail ships."

Actually, the Post Office Department bought eight Junker planes, for spare parts to the value of two additional planes were obtained to keep the other six machines operating. The purchases were made direct from the J. L. Aircraft Corp. at a cost of $200,000. It was announced that 215 planes of American make are in possession of the Post Office Department at this time, of which 65 are now in use. The remainder are either in warehouses or being remodeled.

GERMAN PARTS MAKERS UNDERSELL AMERICAN

SPRINGFIELD, MASS., Feb. 1—German competition in the sale of automobile parts has already been felt by American manufacturers. Investigation by the American Bosch Magneto Co. discloses that German manufacturers are offering South American consumers Bosch magnetos and parts at prices with which the American company cannot compete.

Army Air Appropriation Reduced to $19,200,000

WASHINGTON, Jan. 31—The House Committee on Appropriations has disregarded the appeal of Brigadier General Mitchell, assistant chief of the Army Air Service and has recommended the appropriation of only $19,200,000 instead of the $60,000,000 asked, for the development of aviation as a means of military defense.

In his appeal for funds, General Mitchell insisted that the airplane had become superior to the battleship and that a well-balanced military program must include a military aerial force to be effective in the next war. He stated that a sufficiently large force could be formed and equipped in three years at a cost of $45,000,000 which represented no more than the cost of a battle cruiser. He contended that the armored ship is just as helpless as the armored knight was when firearms were brought against him.

PEUGEOT OUT OF 1921 RACING

PARIS, Jan. 21—(*Special Correspondence*)—Peugeot will not take part in any automobile races this season, according to a decision of the Board of Directors of this important French company. This decision comes as a surprise, for not only has Peugeot been a very strong supporter of racing in the past, but it has a set of 183 cu. in. racing machines all ready. This policy removes a possible competitor from the Automobile Club of France Grand Prix for next July, and makes it very unlikely that any Peugeot cars will be sent for the Indianapolis race. General business depression is said to be the reason for Peugeot's withdrawal from racing.

DAIMLER DOUBLES CAPITAL

NEW YORK, Feb. 2—A dispatch from Germany states that the Daimler Motor Company of Stuttgart, which manufactures the Mercedes car has increased its capital stock from 100,000,000 shares to 200,000,000 shares.

Landing Place Lack Halts Air Progress

Development Dependent Upon National Action in Providing Facilities, Says Professor

BOSTON, Jan. 28—Boston has an opportunity of gaining fame as an aviation center. Prof. E. P. Warner of the aeronautics department of Massachusetts Institute of Technology, yesterday told how this city, this State or this country might advance the use of airplanes, and the secret is for the municipality, the State or the country to provide landing places for the ships of the air.

"We are making progress in perfecting the airplane—making it more serviceable and less dangerous—but the whole program of aviation has practically come to a standstill as far as the public making use of it," declared Professor Warner.

"An aerial taxi-cab in London costs approximately the same as an earthbound taxi in Boston. The charge in England for an aerial taxi is 2s 6d, or 44 cents for two persons per mile. This fare is only two and a half times as large as that for an earthbound taxi and it costs approximately the same amount to travel by airplane in England as by taxi-cab in Boston.

"We can do as well with our American planes and costs if the proper support is given to us by the public and the government. The government ought to encourage private enterprise in aviation, for commercial purposes and as sport.

"But private capital is slow to take up aviation probably because of the high cost of landing places. The nearest landing places to Boston are at Lynnfield and Framingham. In Texas and California the towns are granting lots for landing places and those States should go ahead fast in aviation.

"It would be somewhat more difficult for a city or State in New England to buy landing places because property is more expensive and it is harder to develop aviation here and because there are so many trees and so few landing places in case of emergency.

Potential Business Here

"However, the potential business is here. Airplane service between Boston and New York could be established to make the trip in less than three hours. But very little time would be saved by airplane if a person had to land in Framingham at this end and Long Island in New York."

Professor Warner said the actual costs of air travel in Europe have shown a tendency to steady reduction. He asserted that the fare charge on the London-Paris route was originally 20 guineas, but has since been decreased several times, and now stands at 10 guineas ($37) for the one way journey and 18 guineas for the round trip.

Russian Trade Ban Not Insuperable

Border Countries Present Way to Meet Obstacles—Payments Chief Difficulty

WASHINGTON, Jan. 31—Although the export of automotive products to Russia still is technically under the ban of the State Department on the ground that most of these products might be used for military purposes, there are no insuperable obstacles in the way of American trade with the Soviets. This is admitted unofficially at the State and Commerce departments. Whatever trade is done, however, must be through Scandinavia, Poland or some other country bordering on Russia. Direct shipments could not be passed through the custom house, but no obstacles would be placed in the way of shipments to some consignee in one of the bordering states.

As a matter of fact, the chief difficulty confronting an American automotive manufacturer who seeks an outlet for his goods in Russia is making satisfactory arrangements to get payment for the goods. If this can be done, the hardest part of the problem has been solved.

Trading with Russia is very largely a question of ethics. Manufacturers in other countries are doing it and making no bones about it. It is significant of the high sense of honor of American automotive manufacturers that no applications have been made to the State Department for permission to ship to Russia since the ruling in reference to their products was made by the State Department. Even more significant is the fact that neither the State nor the commerce departments has received any report of surreptitious trading.

Russia offers a large potential market for small tractors and the State Department undoubtedly would permit their export. It would be difficult to make a military weapon out of such a machine. It is no secret that a considerable number of Fordsons have been absorbed by Russia.

No Espionage Maintained

The State Department does not maintain an espionage system in the countries bordering Russia to determine whether its regulations in regard to trade with the Muscovites are being violated. It has no funds to pay secret agents and apparently no disposition to interfere. It is stated frankly that there is nothing to prevent the export of cars and trucks from this country into Russia through Denmark or Poland if the shipper has an agent to get the goods across the line and if he is enough of a financier to work out some satisfactory method of payment.

The Danish committee for the resumption of trade with Russia has established at Copenhagen the International Clearing House with a capital of 2,000,000 crowns to foster trade with the Soviets. The All Russian Central Union of Consumers Societies has deposited 2,000,000 rubles in gold in the Danish National Bank as security for the exchange of goods and credits. This is designed as a revolving fund and it is expected that much of the trade will be on a barter basis.

The Soviets are stated to contemplate increasing this fund to 25,000,000 rubles in gold and it is known that they have established other credits for trading purposes in neighboring countries although most of their commerce at present is going through Copenhagen.

Ford British Output Totals 40,500 in 1920

LONDON, Jan. 14 (*Special Correspondence*)—Ford's Manchester works produced 40,500 vehicles last year and employed about 4000 hands. This output is stated to be 20,000 better than ever before.

Moreover, the result has been financially good, ordinary workers at 60 cents the hour getting $35 bonus and higher paid workers, if engaged not later than 1915, $195 bonus. The rest of the staff eligible for a bonus share also will benefit. Further, 50 per cent or half the workers, by virtue of being investors in Ford stock, on which they get 6 per cent interest per $50, will receive an extra 6 per cent.

Saskatchewan Outlines $24,000,000 Road System

SASKATOON, Sask., Jan. 31—Plans for the construction of 1607 miles of paved highways throughout Saskatchewan have been evolved by C. J. Yorath, city commissioner of Saskatoon, and will be laid before the provincial government for consideration. The program of road building, it is estimated, would cost $24,000,000. It provides for a pavement fifteen feet wide on all highways and the gradual recovery of the money expended by a system of toll-gates such as are still in use on turnpikes in certain American States. California's paved automobile highways are suggested as the model.

URUGUAY PLANS HIGHER TARIFF

NEW YORK, Jan. 31—Increased tariffs to protect the local body building industry is proposed for Uruguay, according to a report from Vice Consul Avery at Montevideo. The Minister of Finance, the Consul states, had sent to the Administrative Consul the following proposals for increases: Automobiles of bonded value not exceeding $700 shall pay an import duty of 10 per cent; those above that value shall pay 20 per cent on the value of the chassis, and 25 per cent on the value of the body. All automobiles shall pay "additional duties" which amount to about 14 per cent. Trucks shall pay 5 per cent of their value but are exempt from paying the additional duties.

Fuel Shortage Hurts South African Trade

Government Aid in Meeting Problem Sought—American Cars Gain Popularity

JOHANNESBURG, SOUTH AFRICA, Jan. 3—(*Special Correspondence*)—The petrol question is still exercising the minds of those connected with the motor trade. Supplies have been more generous during the past month but the situation still leaves a great deal to be desired. It seems that while other sections of the commercial community have received consideration from the Government the motor trade has been singularly neglected in this respect. With all due regard to this the motor trade continues to be one of the most flourishing branches of the community.

Houses have in some cases gone as far as to import stocks of fuel entirely independent of the oil companies and the trade generally seeks either a decontrol with a free market or that the control take the form of a percentage on the landed cost. Letters to the daily press have been suggesting the importation of petrol in bulk instead of the method that at present prevails. Facilities for this measure exist at several ports of the Union and this certainly seems a feasible way out of the difficulty. The question of shipping has however to be considered in this connection but in view of the fact that the shipping position here is gradually getting easier this ought not to be an insurmountable difficulty.

Sales of cars have shown a rise over the figures for last month and dealers are optimistic about the car position. The action taken by certain banking institutions from the countries of export in regard to bills drawn and presented by shippers will tend to make the number of cars now coming to South Africa less and less until the usual facilities are resumed. The decreased prices of cars at the factory caused a stir for a short while, but has not made any difference in sales, and the demand for automobiles continues as strong as ever.

Light Weight Car Popular

The Spacke has arrived and bids fair to become a favorite if the inquiries for a car of this class can be quoted as authentic. The English small models that are imported are too high priced to place them within the reach of many, and the Spacke fills a long felt want in the small car class. Dealers have taken trips to Cape Town in order to fix up rights for various parts of the country.

South Africa is gradually marketing accessories of home invention and manufacture. The latest is a special stand for motorcycles. Very favorable comment has been made by those who have witnessed the ease of control of this stand and quantities are in the process of manufacture in order to cope with the demand that has arisen in motorcycling circles.

Fourth Reserve Bank Finds Trade Better

Lower Prices and Easier Credits Help Inaugurate Buying in Cleveland District

CLEVELAND, Jan. 29—The great army of automobile owners who trade in used-cars in purchasing new cars are coming into the market to boom sales, according to the business forecast of the Federal Reserve Bank of the Fourth District. This is a source that is going to send the automobile business soaring ahead of the volume of trade in the average line of business according to reports received at the bank.

These used car owners have for some time been watching readjustment developments that send down the value of their used cars. Now they are getting to the point where they want to buy before the general readjustment process further reduces their second hand valuation. The bank says that there are fewer buyers of low priced cars in the market.

Motor truck manufacturers report increased buying in practically all sections of the country; public utilities are placing orders, and according to one large producer "there is every indication of considerable business from large industries." Makers of passenger cars comment on the fact that sales at the New York show, while not as large as a year ago when the shortage was so great, were quite in keeping with the records of all previous years.

Speaking of general conditions in the Fourth Federal Reserve District, the bank says that the turn of the year has witnessed a decided change in business sentiment. Reports this month are almost a unit in declaring that signs point to improvement in the business situation. Easier credit conditions are reported Lower prices for commodities mean lowered costs of doing business with a consequent release of additional credit. This may not become apparent until many large inventories purchased at top prices have been worked off, but it is a condition that will ultimately develop as a result of the resumption of business.

Tractor Demand Shows Steady Gain in Year

CLEVELAND, Jan. 29—That the tractor has been slower to come into widespread popularity than the truck or passenger car is not due to lack of merit or lack of desire on the part of the farmer, says L. W. Ellis, of this city, who has taken a leading part in advertising the tractor. Putting the tractor on the farm means the substitution of individual power for motor power, a complete new plan of operation for the farmer, and the scrapping of old plans. The farmer has been slower to work out the solution than they have in other lines, and the tractor is not so old as the truck and passenger car.

But it is working out in Ohio. Ohio farmers, for instance, had 8313 tractors in use last year as compared to 4279 in 1919, a gain of nearly 100 per cent in two years. Figures for the United States show that nearly 200,000 tractors were made and sold in 1920, as compared to the 300,000 that were in use up to the end of 1919.

R. T. Hodgkins, sales manager for the Cleveland Tractor Co., says that prospects for 1921 are even better than they were for 1920. He says that his company has sold many more tractors in December 1920 than they did in the corresponding month a year ago, and that dealers have small stocks on hand.

Bower Bearing Yields $90,000 Profit in Year

DETROIT, Jan. 28—The annual statement of the Bower Roller Bearing Co. shows that during the fiscal year ended Dec. 31 the company made a net profit of approximately $90,000. The report of the company states that at the end of the first six months last year profits totaled $122,400 but that during the other half of the year the company lost $34,-993. The sales for the first half of 1920 totaled $769,755 and for the second half of the year they were $320,395, or a total of $1,090,140. During 1919 the business totaled $1,603,205.

The Bower company paid its stockholders $90,000 in dividends during the first six months of 1920, or about $3000 more than the total net profits made during the year.

The company has kept its personnel of skilled workers during the period of depression and is in a position to go ahead increasing its production at any time. The plant has been given a thorough overhauling and is in better shape to take care of business than ever before. Officials declare that they are confident as to the gradual return of activities in the automobile industry.

TOPP-STEWART ADDS DIRECTORS

CLINTONVILLE, WIS., Jan. 31—The Topp-Stewart Tractor Co. of Clintonville, Wis., at its annual meeting, increased the number of its directors from seven to nine, the new members being H. A. Rindt and Theodore Meyer. Officers were re-elected as follows: President, Dr. W. H. Finney; vice-president, H. F. Zarling; secretary, A. C. Cather; treasurer, Levi C. Larson. Active production will be resumed about Feb. 1 at a materially increased scale, which is required mainly by a wholesome enlargement of foreign demand. Domestic orders also are accumulating at a satisfactory rate.

CREDITORS SUE PERFECTION

MILWAUKEE, Jan. 31—The Perfection Engine Co. has been made defendant in involuntary bankruptcy proceedings by the following creditors: North Milwaukee Foundry Co., with a claim of $2,939; Badger-Packard Machinery Co., $125; Detroit Auto Radiator Co., $720.

Diversity of Crops Urged to Help South

Georgia and Alabama Dealers' Associations Foster Movement to Increase Prosperity

ATLANTA, Jan. 31—A movement to encourage a program of diversification of crops on Georgia farms through a campaign that is to be inaugurated and carried on systematically through every county of the state, is to be fostered by the Georgia Automotive Dealers' Association, according to a decision reached at the annual convention held here.

The impetus to the movement was given by A. R. Kroh in an address before the second annual convention of the association. Kroh, who is himself a practical farmer, pointed out that since 1900 more than 10,000,000 farmers have left the rural districts for the cities and as a consequence the cost of living is mounting higher and higher because America consumes more than it produces.

Kroh went thoroughly into the subject of power farming, discussing this phase of the industry from the dealer's standpoint and showing how diversification of crops on Georgia farms would mean an enormous increase in the demand for power farming equipment, principally tractors.

While the movement to bring about a diversified program will be fostered by the automobile association, bankers, merchants and industrial leaders throughout the state will be asked to assist in the work. Plans are being formulated by association officers to arrange a general meeting for the near future and invitations will be extended to business men to attend. It is believed this meeting will probably be held during the week of the automobile show, March 5 to 12. The principal address will be delivered by Kroh, who will explain the whole program of diversification exactly as it is to be encouraged by the automobile association.

A similar movement is already under way in Alabama, fostered by the Alabama Automobile Dealers' Association. An address was delivered by Kroh at the sixth annual convention of the Alabama dealers held at Albany, Ala., Jan. 24. The following day a conference of bankers, business men and merchants was held at Birmingham, where the movement was endorsed and it was decided to carry it out during the coming year under the auspices of the automobile association.

I. M. C. TO REDUCE WAGES

NEW BRUNSWICK, N. J., Jan. 31—The branch factory of the International Motor Co. here posted a notice yesterday of reduction in wages ranging from 10 to 30 per cent, effective immediately. The working force will also be reduced. The wages of a number of the office force in the toolmakers' division will be cut from 85 to 65 cents an hour, and those of laborers from 55 to 35 cents.

W. R. Campbell to Be New Ford Executive

Nomination As Klingensmith Successor Considered Certain —Jewish Attacks Hurt

DETROIT, Feb. 1—While official announcement is lacking, it is stated on authority that W. R. Campbell, secretary and assistant general manager of the Ford Motor Co. of Canada, will succeed F. L. Klingensmith as vice-president and general manager of the Ford Motor Co. Campbell is now at the Highland Park plant and has been there for several days. He is virtually in authority at the big factory.

Klingensmith held the position of treasurer, but it is understood the duties of that office will be given to some one other than Campbell, who will devote his entire attention to active management of the plant, chiefly along production lines. It is reported that important financial matters in future will be handled entirely by Henry Ford, whereas Klingensmith heretofore negotiated practically all the financial deals.

Campbell is thirty-nine years old. He has been with the Ford company of Canada since it was organized in 1904. Prior to that he was with the Queen City Oil Co. His home is at Walkerville, Ont., where the Canadian plant is located. He is said to be of exceptional ability and Henry Ford is said to have had his eyes upon him for a long time.

The Ford organization still is in more or less of a state of chaos. W. C. Anderson, director of operations in Europe with headquarters in London and Paris, tendered his resignation last week and this was followed by that of Louis Block, in charge of the Philadelphia branch.

Resignations Not Explained

In the absence of statements from officials as to the reason for these resignations and the reluctance of both Anderson and Block to discuss them, semi-official statements are to the effect that the anti-Jewish campaign of Henry Ford's newspaper, the Dearborn *Independent*, is responsible. From a man close to Anderson it was learned the foreign chief had been driven to the point of severing relations with the company by reason of a virtual boycott on Ford products in foreign countries as a result of the attack on the Jews. This man said not only were the majority of foreign dealers of Jewish descent, but that the money in Europe was in the control of Jewish bankers. Likewise, probably a majority of the prospective customers for Ford products were of Jewish origin or closely connected with that race.

Business in the foreign countries, it is said, began to slump several months ago at the outset of the campaign and grew worse rapidly until the point was reached where it became apparent the attitude toward the Ford Jewish fight had practically ruined the business of the company on the continent.

Anderson, who is regarded as one of the most competent men in the foreign field, is said to have made repeated entreaties, appeals and finally demands that the Jewish attack cease, but all of his efforts are said to have been unavailing and instead the attacks became even more bitter. The recent resignation of Vice-President Klingensmith, which was in great measure due to the same cause, convinced Anderson, according to his friend, that there was no alternative and he promptly decided to come to America and tender his resignation.

Anderson Record Enviable

Anderson is widely known among automobile men in America and Europe as "Fuzzy" Anderson. He was one of the many bicycle racers who entered the automobile business at its inception. He joined the Ford company as branch manager sixteen years ago and later was put in charge of the Chicago business after several years in St. Louis. Two years ago he was selected, after a survey of the entire Ford organization, as the man best qualified to take charge of the Ford European business. He was sent abroad with full control of production and sales during the reconstruction period, and established a record that automobile men and Ford officials admit was remarkable.

Anderson has been in Detroit several days, and will be here until sometime this week. While he has no plans to announce for the future, he has been in constant association with leading manufacturers, and his friends say it is not unlikely when he leaves Detroit he will go as the foreign representative of one of the newest cars on the market.

No information could be secured regarding the resignation of Block other than statements of friends that he was prompted by the same reasons that forced the resignation of Anderson.

Ford Sued by Gest for Alleged Libel

CHICAGO, Feb. 1—Morris Gest, theatrical producer, has filed a $5,000,000 damage suit against Henry Ford in the Circuit Court of Cook County, alleging libel in statements published on Jan. 22 in the Dearborn *Independent*, Ford's paper, which has been running a series of attacks on the Jews. Gest takes exception to various statements made, but is particularly incensed at the intimation that he has neglected his parents who still live in Odessa. His counsel asserts that his parents are very wealthy and do not need their son's assistance.

PIERCE PROFITS $1,769,914

NEW YORK, Feb. 3—The report of the Pierce-Arrow Motor Car Co. for 1920 shows net profits after charges and Federal taxes of $1,769,914, compared with $2,491,070 the previous year.

Limited Production Proposed by Ford

Not More Than 5,000 Men at Work—Few Cars to Be Made in February

(*Continued from page* 237)

tical as to the success of the conference.

It is intimated that the resumption of operations at this time may have been due in some measure to the psychological effect it might have on the financial world.

The foremen were the first to arrive at the Ford plant to-day and the next employes to go to work included the best element among the married men with dependents. They were put to work cleaning up the plant and getting the machinery into shape. Manufacture of parts will be resumed before production of cars is begun as the surplus of cars on hand when the plant closed has been exhausted.

W. A. Ryan, general sales manager for the Ford Co. asserts that sales have increased rapidly in the last 10 days in most sections of the country. Cars have been moving from districts where agricultural or industrial conditions caused a backward market and sent to territories where dealers were moving them rapidly.

Newspaper reports of renewed industrial activity in Detroit have been very much exaggerated and have been the result of an attempt to make the outside world believe Detroit was coming back rapidly as a great manufacturing center. Most of the dispatches which have appeared in other cities have been a rehash of stories in local papers which seek to minimize the unemployment situation.

It is true that there is a gradual improvement in the industrial outlook here, but it is coming about slowly and only a few men are taken on at any of the factories. Conditions do not differ in any material way from those which prevailed after the resumption of work following the Christmas holidays. There is some production in most of the automobile factories but it is on a greatly reduced scale and it will be increased only as actual orders warrant.

Negotiations Reported Off

NEW YORK, Feb. 2—While financial papers still are printing numerous stories recounting the alleged financial difficulties of Henry Ford, it is impossible to obtain anything tangible here on the progress of negotiations between Ford and New York banks. There is substantial reason to believe that these parleys have been broken off.

Reports from Detroit are to the effect that Ford has ceased his efforts to obtain financial aid in this city because he considered the bankers' demands unreasonable. It also is understood he flatly refused to permit a bankers' committee or a representative of the banks to supervise the operation of his plants. No statement has come from Ford.

Unsold Cars Load British Markets

Thousands of American Vehicles in Heavy Surplus—Trade Fails to Revive

LONDON, Jan. 21—(*Special Correspondence*)—The turn of the year brought no improvement in the automotive trade in England and conditions generally are no better than they were the last three months of 1920. The slight but definite improvement which was expected after Jan. 1 has failed to make itself evident. The trouble seems to be that no one expected the cessation of buying was going to be so definite and dealers therefore took large stocks of cars while the manufacturers, supposing these cars soon would be sold to the public, continued to manufacture at full speed. The result is that there is in the country to-day a stock of vehicles sufficient to last from six to eight months even if the demand rises to the normal level.

It is reported that Ford, who produced at Manchester in 1920 just 40,000 cars, or nearly twice the best record for any previous year, has between 7000 and 8000 cars in the hands of dealers. Willys-Overland has 2600 cars in stock at Manchester. Its December deliveries numbered only 34. Chandler is reported to have 300 cars unsold; Cole 100 and Jordan 40. The great race course at Aintree, which was operated as a shell factory during the war, is said to be piled high with American motor vehicles such as All-American trucks, Traffic trucks, Dixie Flyers, and Moon cars. The stock of Hudsons and Essex on hand is estimated at from 300 to 400.

English makers are no better off than their American competitors. The Angus-Sanderson company, which started out a year ago with a popular 15 h.p. car has gone into liquidation, as has the Bean company. This takes out of the field two of the three quantity production post war jobs. The Cubitt, the third of this group, still is in operation although its makers had no previous experience along mechanical or engineering lines until after the war. It is interesting to note that before the Bean plant was practically closed two months ago it had reached a production basis of 100 a day which is astounding from a British point of view. Credit for this record is given to Production Manager Conroy, who came here from the Willys-Overland plant at Toledo.

Austin Makes Headway

One English maker who is making a little headway is Austin. He has kept his prices down to a reasonable level and stood the losses which he made all last year, believing that in the end a volume of business would be maintained which would bring financial reward. His output is relatively small, however, probably not exceeding 40 or 50 a week.

Brown Succeeds Dunbar as Clydesdale President

CLYDE, OHIO, Feb. 1—Frank D. Brown, a director and chairman of the finance committee of the Provident Bank & Trust Co. of Cincinnati, has been elected president of the Clydesdale Motor Truck Co., succeeding C. R. Dunbar. Brown is now in Florida but is expected to take an active part in the management of the company of which he has been a director. Other officers elected by the company, are: Vice-presidents, C. R. Dunbar, and A. C. Burch; treasurer, W. P. Dodge; assistant treasurer, J. C. L. Krebs, who has been a vice-president; secretary, Homer Metzgar. The board of directors is composed of the officers and J. H. Baynes and Charles H. Bowker of Northampton, Mass.

Gasoline Prices Drop Over Wide Territory

NEW YORK, Feb. 3.—Announcement of reduction in prices of gasoline and crude oil in virtually all the eastern and midwestern territory have been made this week by the various oil companies. This follows other cuts made in the past few weeks. The first reduction thus far made in the New York and New England territory was announced by the Standard Oil Co. of New York, which marked down motor gasoline 1 cent a gallon. The Standard Oil Co. of New Jersey also announced a cut of 1 cent, the second in the past two months.

The Sinclair Refining Co. has reduced gasoline 2 cents a gallon in Cleveland and has made a second cut in a month in Chicago, where the price at filling stations is 25 cents and for tank wagon delivery 23 cents. The same price has been made by the Standard Oil Co. of Indiana for the entire midwest territory.

Crude oil has been reduced to $2.50 a barrel by the Magnolia Petroleum Co. and the Prairie Oil and Gas Co.

Gasoline Reserves Increase

WASHINGTON, Jan. 29—Gasoline reserves are gradually increasing, according to refinery statistics compiled by the Bureau of Mines for November, 1920, which shows an increase of 50 per cent in the daily average output as compared with 1918. Production of gasoline for November increased by 62,000 gal. daily over the October output. Total stocks at refineries Nov. 30 amounted to 354,835,764 gal. as compared with 378,133,185 gal. for the same month last year and 270,072,011 gal. in November, 1918.

Petroleum Stocks Increase

WASHINGTON, Jan. 31—Oil production in the United States in 1920 totaled 443,402,000 bbl., while consumption reached the unprecedented total of 531,186,000 bbl. Despite the excess of consumption over production, the end of the year showed a net increase in petroleum stocks of more than 10,000,000 bbl.

Goodyear to Receive $45,000,000 New Funds

Announcement of Refinancing Details Awaits Adjustment of Merchandise Claims

NEW YORK, Feb. 2—The adjourned meeting of Goodyear Tire & Rubber Co. stockholders, set for yesterday has been again adjourned until Feb. 11 due to delay in satisfactory consummation of refinancing negotiations. Officials of the company state that they hope to announce the full refinancing plans on Feb. 11, and report that satisfactory progress is being made in the negotiations.

It is stated on authority that the negotiations for a permanent loan have been practically concluded and that the only matters now remaining to be adjusted, are with the company's large number of merchandise creditors. Under the refinancing plan the company is to receive approximately $45,000,000 in new money, it is stated. This will permit immediate retirement of the notes for $28,800,000 negotiated by the Goldman-Sachs banking group, which mature Feb. 15.

Consummation of the refinancing will also enable the Goodyear company to increase production, officials state. According to Vice-Presidents G. W. Seiberling and G. M. Stadleman, the company's business for January showed an increase of slightly more than 50 per cent over December. This is taken to indicate a strong upward trend in the tire industry, as an increase of only 25 per cent over December business had been forecast.

Orders for February and March business are coming in so rapidly, according to Mr. Stadleman, that as soon as the refinancing is definitely concluded, the company expects to increase production more than 100 per cent, and will go to fully 18,000 tires daily at the earliest possible date. Estimates now place Goodyear production at between 8000 and 8500 tires daily.

Stadleman is mentioned prominently in industrial and financial circles, as the man who perhaps will succeed to the presidency of the Goodyear company, should there be any change in official personnel in compliance with terms of the refinancing program. It is regarded as not improbable that President F. A. Seiberling, although remaining with the company, will surrender direct control to interests dictated by bankers negotiating the company's loan.

DANIELS FAVORS OIL EMBARGO

WASHINGTON, Feb. 2—Senator Phelan's bill which would authorize the President to embargo petroleum exports has been approved by Secretary of the Navy Daniels. The bill is now before the Senate Naval Committee and it is expected the measure will be reported. Senator Phelan wants immediate action but it is probable appropriation bills will block its early consideration. Exportation of California oil to Japan caused the bill.

Surplus Tire Stocks Show Big Reduction

Heavy Buying May Cause Spring Shortage, Officials Believe—January Sales Heavy

AKRON, Jan. 29—Estimates prepared by rubber manufacturers of Akron indicate that the country will be faced with a tire shortage, possibly by March 1, unless tire production is increased materially at once. Great inroads have been made into the surplus of tires, estimated conservatively at 10,000,000 last September, and actual production of tires now is only one-fourth of consumption, according to estimates prepared by the B. F. Goodrich Co.

Tire production, according to Goodrich estimates, has been at the rate of not more than 8,000,000 tires a year, or about 660,000 a month since last September. Although tire sales are admitted to have slumped, due to the financial depression, business is improving as indicated by the fact that Akron tire factories expect to do more than $50,000,000 worth of business this month.

Based upon the reports of January business booked by Akron tire companies, and upon the estimates of the Goodrich company that 32,000,000 tires are needed this year to equip the 9,295,252 motor vehicles now in use in America, the monthly demand is 2,000,000 tires in excess of actual production.

Goodrich, by restoring its ten-hour factory shifts, has increased tire production materially this month, while a further increase to a basis of 10,000 tires daily will become effective this week. Goodyear, according to the latest available information, has been manufacturing not to exceed 6500 tires daily. Under conditions of the temporary loan of $28,300,000 negotiated with Goldman-Sachs Co., New York, which matures Feb. 15, the Goodyear company is precluded from increasing its payroll.

Plenty of Orders on Hand

It is stated authoritatively by Goodyear officals, however, that with negotiations satisfactorily consummated for permanent refinancing to replace the temporary financing program, it will become necessary to increase production in order to keep production apace with present increasing demand. Goodyear has not less than $15,000,000 worth of business booked for January delivery, while February orders are coming in in an encouraging manner. The increase in production, it is stated, will be accomplished by restoring present factory forces to normal hours, and that additional men will not be employed in the immediate future.

Miller Tire & Rubber Co. is slowing down production somewhat but expects to resume on a basis closely approaching normal, within a few weeks. Miller, which is recognized to be in as sound a financial condition as any rubber company in Akron, has not felt the tire sale slump or business depression as severely as other companies until this month. The lull in production is merely transitory and is enforced so that present surplus of finished product can be absorbed, Miller officials state.

The open winter has been largely responsible for the present improvement noted in the tire situation. "The possibility of a spring tire shortage is greatly increased by the open winter," state Goodrich officials, "and the surplus existing last fall cannot be counted upon to ward off a shortage when the full buying movement starts."

River Rouge Damages Fixed at $470,142

DETROIT, Jan. 29—A jury in Federal court hearing the River Rouge condemnation proceedings through which Henry Ford seeks widening the river channel to permit the passage of heavy freight steamers to and from his blast furnaces, handed down a decision this week awarding a total of $470,142.30 to property owners whose land had been condemned. The warrant is considered a distinct victory for Ford, though the government rather than Ford appeared as plaintiff in the action. However, in view of the fact that Ford was to be the chief beneficiary of the improvement, he agreed to pay all awards and costs of the litigation in the government's behalf and at the outset was compelled to deposit Liberty Bonds and other securities amounting to approximately $4,000,000 to cover costs and damages that might be assessed as a result of suits by property owners.

It has been more than four years since the War Department advised dredging the Rouge river, and immediately after Congress appropriated money to cover the work property owners began filing suits to prevent the condemnation and carried their case through the Circuit Court of Appeals.

The largest single award was made to the Delray Inland Salt Co. which was given $73,244.16, although it only asked $40,000. Other plants were cut down materially in their damage claims. The completion of the River Rouge project is expected by August 1.

FORD WORKS OUT RAIL PLANS

DETROIT, Jan. 28—It has been announced by officials of the Detroit, Toledo & Ironton Railroad, that it is the desire of Henry Ford, who controls the road, that as he is against the idea of working on Sunday, the road will not operate trains on that day. There is no let-up in the plan to put the road on a thoroughly efficient and profitable basis. After the winter months the real big work will begin, although already considerable headway has been made in that direction. For instance, it is stated that a large number of freight cars, formerly used by the road, have been discarded being considered by the experts chosen by Henry Ford as a liability to the road's good operations.

Packard Shuts Down To Balance Stocks

Shortage of Bodies Due to Strikes Upsets Schedules—Western Sales Slump

DETROIT, Jan. 29—Packard Motor Car Co.'s plant closed at noon to-day for an indefinite period to permit of balancing inventories, according to E. F. Roberts, vice president in charge of manufacturing. Plant officials expressed the hope that conditions would permit of resumption of production in ten days but employees were informed that the maximum period of idleness would be thirty days. More than 3000 men in the factory and many of the employees in the offices were included in the suspension order.

A decided slump in the West following buying activity during the week of the New York show and for a few days thereafter is declared to be in the main responsible for the order, though a strike of body finishers at the Packard plant and also at the plants of two independent concerns which are employed chiefly on Packard work, prevented completion of cars and resulted in other departments getting so far ahead of the body plant as to force cessation of production until the body plant could catch up. The strike began three weeks ago when, according to employees, a cut of 44 cents an hour went into effect.

The following statement was made today by Vice President Roberts:

"We are closing today in order to permit balancing our inventories but we hope to resume within the next ten days. At all events the plant will not be closed longer than March 1. Many circumstances have combined to bring about the decision to close, though it is due chiefly to the fact that some of our departments have to run too far ahead of others resulting in greatly unbalanced inventories. Then too there has been a check in the sales mainly in Western territory though there is every indication that that section now is passing through the depression period and in a short time will show signs of reaction and improvement such as has resulted in the East following the recent distinct slump there."

Present Demand Satisfactory

The closing order coming on the heels of reports that Ford would reopen in part Monday was a great surprise though manufacturers were inclined to attribute Packard conditions chiefly to the labor situation in the body plant rather than over-production or lack of demand. Packard has been building about 400 single sixes a month for the last four months. The plant closed for inventory during the holidays but reopened Jan. 3 and had been running steadily since that time. Orders stopping all incoming freight shipments also were sent out today.

Cleveland Puts Over Many Sales at Show

Attendance Records Indicate Wide Public Interest—Factory Representatives Stir Dealers

CLEVELAND, Jan. 29—Cleveland's twentieth automobile show closed to-day with all attendance records broken by fully 30 per cent and with an encouraging report on both wholesale and retail sales. No actual count of orders is ever made here but there are indications that the aggregate will run at least a little way into the hundreds in retail business alone.

The show received wide and dignified attention from the Cleveland newspapers and brought into town prospects from all of northern Ohio. Dealer meetings, several of them addressed by high factory executives, avoided frills and resulted in a quite satisfactory placing of wholesale orders.

With a wide diversification of industries, Cleveland has not suffered in the readjustment as have some centers but the heavy car registration in Ohio, one to every nine of the population, has created a serious used car problem, which had a good deal to do with preventing sales at the show from attaining even more encouraging totals.

The large attendance at the show was in spite of an increase in the admission fee from 50 to 75 cents.

Baltimore Develops Trade

BALTIMORE, Jan. 31—From a buying standpoint, the automobile show which closed Saturday night probably was 50 per cent as good as that of last year. Firms which did an actual business of eight or ten cars in 1920 and 1919 were well satisfied with four or five last week. There appeared to be more interest in the high-priced cars than in the cheaper ones. The attendance was unusually large but it was obvious that many of those who visited the show were merely sightseers.

Milwaukee Sells 300 Cars

MILWAUKEE, Feb. 1—Informal reports of sales at the Milwaukee show indicate that upwards of 300 cars were sold at retail. Since the close of the show dealers report that business has been of satisfactory volume and much in excess of the pre-show period. Unofficial figures of attendance at the exhibit disclose that approximately 48,000 paid admission. Lists of about 2500 prospective buyers were built up from the show visitors. Distributers in the territory say the show was unusually successful in stirring the dealer and sub-dealer trade.

Addresses at the annual dinner of the Wisconsin Automotive Dealers Association were by Alfred Reeves, manager of the National Automobile Chamber of Commerce; David Beecroft, directing editor of the Class Journal Co., and A. R. Kroh, of Goodyear.

TRAVELING SERVICE TRIED IN ENGLAND

LONDON, Jan. 14.—(*Special Correspondence*).—The Associated Equipment Co. (Inc.) of Walthamstow, London, E., whose fame was largely made by Sam Wallace, production engineer there during the war period, and now chief director of the Wallace truck interests, has started a truck service plan which is making good and earning favor by rapid renovations of A. E. C. trucks when in trouble. The company has six traveling repair shop trucks covering the whole of England and Wales. Each is allotted a territory to tour in, and carries a stock of replacement parts and workshop plant. When a breakdown is reported the district repair truck makes for the spot and the job proceeds until finished. Some record times are reported for such jobs as engine overhauls.

Congressmen Getting Protests of Dealers

(*Continued from page* 236)

market at Los Angeles and dealers in that city, with the exception of one who is acting as agent for the Slough company, are protesting vigorously to their representatives in Congress in the hope that something may be done to amend the law. The Congressmen view these appeals with much sympathy and believe an injustice is being done to the American truck industry but there is no action they can take as the law stands now. The suggestion has been made, however, that some amendment be proposed. The appeals of individual dealers are being backed by the representative here of the Los Angeles Chamber of Commerce which has gone on record as opposed to the sale of these trucks.

It is understood other chambers of commerce throughout the country will be asked to take similar action and thus arouse sentiment against the purchase of these trucks. As the situation stands at present, it is largely a moral issue and individuals in the market for motor vehicles must decide for themselves whether to buy these rebuilt army trucks from a British company rather than a used vehicle in the same general condition for a little more money.

New York Agents Named

NEW YORK, Feb. 2 — Roskam-Scott Co., 1869 Broadway, will represent the Slough Trading Co. in New York. E. I. Roskam, head of the company, said arrangements had been made for the handling of a large quantity of parts, reshipped to this country by the Slough company, and that a percentage of the truck total would also be handled here. No arrangement had been made for the shipping of any definite number, he said.

Dealers Contracts to Be Considered

N. A. C. C. Accepts Invitation From N. A. D. A. for Conference on Relations

CHICAGO, Feb. 2—Directors of the National Automobile Chamber of Commerce to-day accepted the invitation of the National Automobile Dealers Association for a joint conference to consider manufacturer and dealer relations, including the question of contracts.

The directors, in a resolution, extended greetings to the dealers association in convention here and referred to the dealers action in inviting the conference as one based on a broad view of the good of the industry.

It is expected that the manufacturers and dealers will appoint their committees in the near future and that the general question of relations between makers and merchandisers of cars and trucks will be taken up.

The traffic committee of the N. A. C. C. reported carload shipments from the factories in January 35 per cent of those in January, 1920.

The Chicago show has gone ahead of that in New York in attendance for the first time in history. The first three days had the largest paid attendance at any national show.

SPRINGFIELD PLANTS ACTIVE

SPRINGFIELD, OHIO, Feb. 2—A. K. Stewart of the Hare's Motors Corp., formerly with the Packard Motor Car Co., has assumed his new duties as manager of the Kelly Springfield Motor Truck Co. Production is gradually increasing at this plant.

All departments at the plant of the Westcott Motor Car Co. resumed operations yesterday on a 50 per cent basis. More men will be added soon, it is announced by General Manager H. G. Root.

REPUBLIC TIRE OUTPUT LOW

YOUNGSTOWN, OHIO, Jan. 29—Operations at the Republic Rubber Co., scheduled to start Jan. 10, were not under way until this week. Cord tire production is on only a small scale. Only the mechanical rubber goods department is working to near full production. The announced eight-hour shift plan has not been put into effect and it is doubtful now whether or not it will be adopted.

MULLINS REDUCES PRODUCTION

SALEM, OHIO, Jan. 29—Production has been almost entirely suspended at the Mullins Body Co., according to officials who assert that they have no definite information as to when work will be resumed. Although a quantity of orders is unfilled, the Mullins company has been notified to withhold shipments.

Efficiency to Bring Wide Use of Trucks

White Sees Greater Trend to Highway Shipping — Time Economy Important

CLEVELAND, Jan. 29—Windsor T. White, president of the White Motor Co., and chairman of the National Motor Truck Committee of the National Automobile Chamber of Commerce, in giving a review of what the motor truck is doing toward transporting freight of the country, says that more than 10,000 regularly established rural motor express lines are in operation and the number is increasing constantly.

The coal situation offers a striking proof of the country's dependency on the motor truck as a means for increasing production, and economical distribution. Of the 4000 coal mines in the country 2000 are without railroad connection. Of the 5000 precious and semi-precious ore mines in the country about 2500 use motor trucks.

At Terre Haute, Ind., coal is being hauled directly from the mines to the consumer. The mines are several miles east of the city and are owned by the coal dealers. Due to the fact that this operation lies within the short haul sphere, the truck was able to cut the delivery time from weeks by railroad to days. The Civic Association of Birmingham, Ala., has contracted with a motor truck corporation to move coal direct from the mines to the consumer at the rate of 200 tons a day.

At such centers as New York, Cincinnati, Minneapolis, Cleveland, St. Louis and Grand Rapids, motor freight terminals have been established. These exercise important influence on transportation and production. In Cincinnati alone 66,000 cars were released for through traffic; shipments that took four days by railroad cars from one part of Cincinnati to another were transferred in four hours by truck.

The conditions of competition for motor transportation at present are different from those which stimulated the rapid increase in the use of trucks during the war. Except for perishable goods, time is the only consideration. The older transportation systems will eventually adjust their facilities to accommodate the traffic for which they are best adapted so that the motor truck must bid for business on the basis of efficiency alone.

OHIO NAMES NEW ENGINEER

YOUNGSTOWN, OHIO, Jan. 29—Ett S. Smith, city service director, becomes State highway engineer Feb. 1, according to announcement from the office of Governor Davis. Smith has been county highway engineer for a number of years until Jan. 1, 1920, when he was named service director. His record has been a distinct improvement of city streets and great advances toward repair of main thoroughfares that have been "sore spots" for several administrations. He is recognized as one of the leading engineers of the State. He has been an owner and operator of passenger cars and commercial vehicles for several years and is known to look with high favor on the motor vehicle and its large benefits to society. It is believed by automobile men that his efforts will be directed toward building roads that will stand up under modern transportation.

Federal Aid Extension Favored by Congress

WASHINGTON, Jan. 31—The Senate Committee on Post Offices and Post Roads and the House Committee on Good Roads have favorably reported bills amending the Federal Aid act simplifying and extending Government assistance to the States in construction of highways.

The measure sponsored by Senator Phipps of Colorado, provides that the present limit of $20,000 per mile which may be contributed by the Federal Government should be increased in those States in which the percentage of participation required of the State is decreased under another section of the bill. While this section would not increase the amount of Federal aid, it would allow public land States to avail themselves of their allotments by appropriating a smaller amount of State funds. The Senator announced to-day that he would call it up for early consideration.

Ohio Court to Rule on Bridge Weight Limit

YOUNGSTOWN, OHIO, Jan. 29.—Decision by Judge Cooper in the suit of Albert Buehrle and others, against the county commissioners, seeking permanent injunction against enforcement by the commissioners of stringent regulations restricting weights of loads carried by motor trucks over bridges on main market highways will be made Feb. 5. The plaintiffs introduced evidence showing that there had been a number of arrests of truck operators charged with violating the weight limitations prescribed by the commissioners, a maximum of eight tons gross and as low as five tons gross, including 17 bridges.

The plaintiffs contend that the statute requirements are twelve tons gross and that the commissioners are required to maintain bridges at that loading. The commissioners contend that an act passed some years before motor vehicles were generally used in transportation gave them the right to restrict bridge loading. This act has as its principal feature a restriction "that not more than 40 head of horses or cattle" shall be on a bridge at one time.

C. W. REID DIES

WASHINGTON, Jan. 31—C. W. Reid, manager of the Transportation Bureau of the Federal Highway Council, is dead here after a brief illness.

METAL MARKETS

IN all departments of the iron and steel markets stress is being laid on the silver lining which the clouds are beginning to disclose. Resumption of operations by automotive plants that have been shut down was naturally preceded and accompanied by some purchases in the iron, steel and non-ferrous metal markets. Every one interprets what buying has taken place to suit his own particular purposes. A large pig iron interest says: "It appears as though at least one buyer has reached the conclusion that the pig iron market has struck bottom and that the present is as good a time as any to buy for the first half. He has backed this opinion to the extent of 3000 tons for prompt shipment to be stored on the yard for future use, and is inquiring for approximately 10,000 tons of another grade for use over the first half." To which the buyer of a fair-sized tonnage of pig iron, when asked if he was the purchaser alluded to in the foregoing, retorted: "I am not backing any such opinion. In fact, I have no opinion whatsoever to back. But my plant needs pig iron for prompt shipment and I am trying to cover part of our wants over the next six months." Similar conditions are encountered in finished steel. Some of the mills have received modest sheet orders from automotive buyers. From the buyer's point of view, the placing of these orders is not to be interpreted as denoting anything else than that he requires the material and, therefore, is willing to pay the seller's price. If the latter has reached the conclusion that this modest buying indicates that buyers have made up their mind that prices will not go lower, such a deduction is utterly unwarranted. In fact, most buyers, and especially those who are now placing orders for small tonnages, are of the belief that there will be a further downward readjustment in prices. But they believe that it will come gradually and that it can be best and easiest brought about by a resumption of buying on a conservative scale, so that competition between the mills will be encouraged, and those which are really anxious to maintain a fair rate of operations will have an incentive to offer inducements for a corresponding backlog of orders.

Pig Iron—In spite of the ado that some Pittsburgh correspondents make about the coming of a $30 valley market, the fact is that they are rehashing ancient history. Published quotations notwithstanding, the market has been a $30 affair ever since Jan. 2. In fact, there have been sales at $1 and $2 below that level, but none on a higher basis.

Steel—The largest Chicago district independent is reported to be cutting sheet prices, but Youngstown district rolling mills claim to be maintaining previous quotations. Only a slight improvement is noted in the interest manifested by automotive parts makers in cold finished steel bar offerings. Further reductions are reported in bolts and nuts from the Middle West.

Ferro-Vanadium—The Vanadium Corp. of America has fixed its 1921 price for ferro-vanadium, open hearth grade, at $5 per pound, contained, base. For low-silicon and low-carbon alloy extras range from $1.50 to $2.

Aluminum—Importers have revised their price views upward and appear unwilling to shade 25c., duty paid, for 98 to 99 per cent virgin ingots. The domestic manufacturer's price remains unaltered.

Tin—Rumors that the Federated Malay States Government had reduced the minimum price for Straits tin caused a break followed by speculative ups and downs.

FINANCIAL NOTES

Packard Motor Car Co. inventories, including finished vehicles, show a total of $16,683,605 as of Nov. 31 last. This compares with $16,063,189 as of Dec. 31, 1919. Between Sept. 1, 1920, when Packard's fiscal year opened, and Nov. 30 there was an inventory reduction of slightly more than $1,000,000. In accounts for the year ended Aug. 31, 1920, the company set aside a reserve of $2,500,000 to offset possible depreciation in inventory values, to be determined from physical inventory as of Dec. 31. Apparently no serious depreciation in value has occurred.

Gillette Motor Products Co. stockholders at a meeting this week voted to increase the capital from $150,000 to $300,000. R. N. Gillette, J. D. Stewart, B. H. Carnahan, B. E. Githens and J. A. Golden were named directors. The plant, which manufactures floor and running boards for automobiles and trucks, resumed operations Monday after a shutdown of three months.

H. H. Franklin Mfg. Co. estimates inventory as of Dec. 31 at $8,160,000, of which $4,140,000 is work in process and $4,020,000 stores inventory. This compares with a total of $6,384,446 as of Dec. 31, 1919. The current inventory shows a big reduction from the peak during the year.

New Castle Rubber Co. schedules in bankruptcy as filed in the United States District Court at Pittsburgh show liabilities of $3,833,567 and assets of $745,021.

Kelly-Springfield Tire Co. has had listed on the New York Stock Exchange $1,250,000 additional common stock, on notice of issuance as a stock dividend.

Eisemann Magneto Corp. paid a regular quarterly dividend of $1.75 a share on the preferred capital stock of the company Feb. 1.

Studebaker Corp. has declared the regular quarterly dividend of 1¾ per cent on preferred and common stocks, payable March 1.

Buckeye Traction Ditcher Co. will increase its capital stock from $300,000 to $1,000,000 to provide for increased operation.

Maxwell to Receive Balance of Claims

DETROIT, Jan. 31—Creditors of the Maxwell Motor Co. holding claims amounting to less than $5,000 have been ordered to present their claims to Special Master William S. Sayres, Jr., on or before Feb. 15 in the suit of Jenks & Muir Mfg. Co. against Maxwell Motor Co. Inc., a friendly action in which the company joins.

The suit was filed according to Special Master Sayres for the purpose of permitting the reorganization plans to proceed without interruption from the smaller creditors who necessarily would be inclined to file suits, attachments, garnishments, etc., and in fact, would enter into a contest to see which would be first to tie up the company's property. All of the claims above $5,000 were deposited with the reorganization committee, and the smaller claims will be given hearings by the Special Master and will be settled in full or on an equitable basis, he said.

While the Jenks & Muir action in no sense involves a receivership, it is in effect the same thing inasmuch as the plant will have to be sold by the Special Master after the hearings, and it is presumed the reorganization committee will be on hand and become buyer of the plant.

Dragon Stock Sales Banned in Illinois

CHICAGO, Jan. 28—In mandamus proceedings brought in the Sangamon county court under the "blue sky" law by the Dragon Motors Corp., a Chicago company, Judge E. S. Smith upheld the action of Secretary of State Louis A. Emmerson in refusing to file the application of the corporation for permission to sell its stock in Illinois.

The company organized to manufacture automobiles had begun an extensive advertising campaign to sell its stock. The value of the assets of the corporation was fixed at $581,000, a figure obtained, according to the attorneys for the company, by an appraisal on the basis of production of the plant, which was not new, less depreciation.

DUPLEX NAMES NEW OFFICERS

BEAVER DAM, WIS., Jan. 31—The Duplex Storage Battery Co., which moved its works from Milwaukee to Beaver Dam, Wis., several months ago, has reorganized its official personnel and management. The new officers are: President, J. W. Deniger, Beaver Dam; vice-president, Herman L. Schickel, Milwaukee; secretary-treasurer, M. A. Jacobs, Beaver Dam; general manager, Peter M. Kettenhofen; factory superintendent, Joseph Mollerus; directors, John V. Zweck, Beaver Dam, and A. H. Luckenbach, Chicago.

KELLY TRUCK ADDS TO FORCE

SPRINGFIELD, OHIO, Jan. 28—Gradually the force at the Kelly-Springfield Motor Truck Co. plant is being increased. Orders are coming in slowly. With the additional facilities provided not long ago the company is in a position to meet any demands of the trade.

GEORGE HALLEY DIES

LONDON, Jan. 14 (*Special Correspondence*)—The death has occurred this week of George Halley, founder of the well known Glasgow company, makers of Halley trucks. His first vehicles were steamers, but more recently the company concentrated wholly on a 6-cylinder truck which is probably the only "six" truck of British make.

TO ACT ON SLOCUM OFFER

NEWARK, N. J., Feb. 2—Creditors and stockholders of the Slocum, Avram & Slocum Laboratories, Inc., have been directed to show cause on Feb. 14 why the receivers should not accept an offer of $161,000 for the property of the company exclusive of land, buildings, equipment and accounts receivable.

BANK CREDITS

NEW YORK, Feb. 3—While the week-end bank statements seemed to warrant the predictions for easier money, the local loan market last week showed a firmness which became pronounced on Monday of this week when call money reached 8 per cent. During the last week call money ruled at 7 per cent, as compared with a range of 6 to 7 per cent the week before. There was little activity in the time money market. Demand was light and the supply of loanable money was not plentiful. The single rate of 6½ per cent was quoted for all maturities up to six months until Monday, when a range of 6½ to 7 per cent was established. A uniform rate of 6 per cent was quoted a week ago. Loans secured by all-industrial collateral were quoted at about ¼ of 1 per cent higher.

The Federal Reserve System as a whole continued the improvement which had been taking place in its reserve position during the month of January. The gold reserves increased $10,368,000, while Federal Reserve notes in circulation declined $24,562,000. Total bills on hand declined $29,446,000 and total earning assets $32,675,000. As a result, the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against net deposits, increased from 55.6 per cent to 56.5 per cent.

The continued rise in sterling and francs was again the feature of the foreign exchange market. Other European exchanges continued to move up sympathetically. Apparently, an expectation of a favorable outcome to the deliberations of the Allied premiers at the Paris Conference was responsible in a large degree for the activity in the foreign exchange

The stock market was very quiet, with the total turnover for the week at less than 2,700,000 shares. The bond market also was quiet, with indications that the recent rise in prices for high grade securities has received at least a temporary check. This probably is due in part to the flotation of high-coupon-rate foreign securities and the expectation of further similar flotations in the near future. The over-subscription of the Belgium 20-year 8 per cent loan and of the Pennsylvania Railroad 6½s indicates the continued acceptability of such new issues in the investment market.

SEEK GLAMORGAN REFINANCING

SPRINGFIELD, OHIO, Feb. 2—An effort is to be made by stockholders to reorganize and refinance the Glamorgan Tire & Rubber Co., which has plants at Delphos, Oakhill and Byesville. Fifty stockholders met here this afternoon by order of the United States court at Toledo to determine what they desired to do. A new board of directors was elected to serve with Receiver Arnold V. King. It is stated that the assets amount to $611,000 and the liabilities are $650,000, according to the auditor's accounts.

MEN OF THE INDUSTRY

E. A. Taylor, formerly production engineer of the Pierce-Arrow Motor Car Co., has been appointed works manager in charge of production for the Liberty Motor Car Co. Before going with the Pierce-Arrow Co., where he was responsible for plant layout and the installation of progressive assembly as well as criticisms of design from a manufacturing point of view, Taylor was in charge of the manufacturing department of the Cadillac Motor Car Co. for two years and later was in charge of the Maxwell Motor Co.'s plants at Detroit and Dayton. He became general superintendent of the Chalmers plant in 1917 and was in complete charge of important war work in addition to the manufacturing of cars. He joined the Pierce-Arrow organization in 1919.

W. F. Taylor, New York, has been appointed eastern sales director of the Acason Motor Truck Co. Taylor was formerly sales manager for the Federal truck distributer in Philadelphia and later was associated with his brother in handling Signal trucks in New York territory.

D. Minard Shaw has been appointed field representative of the Briscoe Motor Corp. Shaw has been for several years connected with Briscoe distributing interests in the South. He will make his headquarters at Memphis, Tenn.

J. A. Palmer has become sales manager of the Neville More-Room Steering Wheel Co. of Wayne, Mich. He will have charge of sales and advertising. Palmer has been connected with the Burroughs Adding Machine Co.

James N. Gunn, president of the United States Rubber Co., has been elected president of the Lincoln Highway Association, succeeding F. A. Seiberling, president of Goodyear Tire & Rubber Co., who resigned.

Clifford M. Sparks, formerly captain of the University of Michigan football team and who is widely known in athletics, has been placed in charge of sales for the Sparks-Withington Co. at Jackson, Mich.

C. W. Hodges, Galesburg, Mich., has purchased the interest of Henry Lane of Kalamazoo, in the Kalamazoo Chain Co. and the name of the concern has been changed to the Hodges Chain Co. of Galesburg.

Glen D. Hiller, formerly sales manager of the Nelson Motor Truck Co., has been appointed assistant general manager in charge of sales of the Triangle Motor Truck Co., St. Johns, Mich.

Arthur H. Lacey, formerly assistant engineer of the Hall-Scott Motor Car Co. and latterly chief engineer at the Moon Tractor Co., has established a consulting engineering office at Oakland, Cal.

E. G. Edwards, Chicago, for many years associated with George W. Kellogg, founder of the Kellogg Mfg. Co., has been elected to the board of directors of the Wayland Specialty Mfg. Co., Inc.,

R. J. Firestone has been elected a vice-president of the United States Motor Truck Co., Cincinnati. Firestone has been connected with the rubber industry for a number of years.

Louis H. Dusenbury has been named vice president, and Harold W. Schwab, secretary, of Louis Dusenbury & Co., Inc., upholstery manufacturers, New York.

A. N. Pollen of London is at the St. Regis Hotel, New York, investigating the local conditions with a view of bringing the Daimler car to this country.

S. L. Warner has resigned as vice-president and general manager of the National Tire & Rubber Co. to join the Robinson Clay Products Co., Akron.

L. A. Brown, formerly district manager for the United States Rubber Co., has been elected president of the Grand Rapids Tire & Rubber Corp.

Omar Wicklin has been appointed assistant western sales manager of the Moon Motor Car Co. and will make his headquarters at Los Angeles.

George W. Copp Co., Inc., has located a new plant at Long Island City for the building of winter tops and automobile bodies.

A. G. Maney and H. L. Franklin have been elected directors of the H. H. Franklin Mfg. Co. and O. A. Lawton has retired.

Andrew J. Pierce Dies; Had Built New Engine

CHICAGO, Jan. 29—Andrew J. Pierce, builder of the old Pierce motor car which was taken over by the J. I. Case T. M. Co. of Racine, died here yesterday of pneumonia. Mr. Pierce was born in Rochester, N. Y., on Jan. 11, 1859, and after working on a newspaper in that city, became associated through the efforts of the owner who perceived his mechanical bent with a well-known machinist in that city. In 1887 he moved to Racine and became connected with the Racine Hardware Co. in charge of the engine production department making an oil engine.

In 1892 he entered into business for himself, manufacturing a gasoline engine of his own invention which was a long step in advance at that time in power machines and organized the Pierce Engine Mfg. Co. After a few years, he established and built a large plant at Lakeside, a suburb of Racine, and formed the Pierce Motor Co. for the manufacture of the Pierce automobile, this being an out-growth of the engine company.

The Pierce company was sold in 1910 to Case who continued to manufacture the Pierce car for two years. A new engine was then adopted and the Pierce name discontinued.

Mr. Pierce was a mechanical engineer, and a designer and manufacturer of gasoline engines. He has been allowed many United States patents on engines which have been used in launches, automobiles and stationary machinery and at the time of his death, had just perfected and obtained letters patent on a new engine for which he claimed great efficiency.

BARLEY NAMES NEW OFFICERS

KALAMAZOO, MICH., Jan. 31—Reports filed at the annual meeting indicate that the Barley Motor Car Co., makers of the Roamer, enjoyed a very prosperous year during 1920. The election of officers resulted in the naming of A. C. Barley, president; C. G. Barley, Marion, Ind., vice-president; C. E. Stephenson, treasurer, and George B. Hopkins, secretary and assistant to President Barley. Hopkins was also added to the board of directors, which includes the officers and M. A. Barley of Kalamazoo and Howard Gould of New York.

INDUSTRIAL NOTES

Security Sales Corp., with offices in New York and Chicago, has been dissolved, but has been granted the privilege of operating within the respective territories as factory branches of the Security Mfg. Co., Los Angeles. Lea J. Orr is in charge of the Chicago office and Marcel J. Orr of the New York branch.

Larco Wrench & Mfg. Corp. has purchased the plant and wrench business of the Cochran Mfg. & Forging Co., 78th Street and Woodlawn Avenue, Chicago. The Cochran company and its forging business is now being operated as the Great Lakes Forge Co., at 119th Street and Racine Avenue.

Cincinnati Milling Machine Co. has bought an interest in the Cincinnati Grinder Co. and will manufacture the latter company's line of machinery. The Grinding company will continue the sales end of the business.

Wharton Motors Co., Inc., Dallas, Texas, is completing the first unit of its plant. It will manufacture a line of cars, trucks and tractors.

Autocar Co. has increased its directorate from seven to nine with the addition of J. Howard Reber and Roscoe T. Anthony.

Block Rubber & Tire Co., Indianapolis, has awarded a contract for the first unit of its new plant estimated to cost $100,000.

Lincoln Motor Car Co. will continue operations on half-time for several weeks. It reports a gradual increase in orders.

Vim Tractor Co. has purchased the patent rights, patterns, etc., of the Tiger Drill Co., Beaver Dam, Wis.

Mac-Lar Battery Co. assets will be sold at auction on Feb. 14 by the Detroit Truck Co., receiver.

Locomobile Co. has reduced wages at the factory 10 per cent.

MOTOR WHEEL UNITS START

LANSING, MICH., Jan. 28—All units of the Motor Wheel Corp. are in operation this week, the Auto Wheel unit having been started Monday morning, as was also the Gier Pressed Steel plant. The Pruden Wheel unit was started some time ago, and the southern unit in Tennessee, which produces raw material for the Lansing plants, has been going at full blast for several weeks.

VICTOR ON 300 DAILY BASIS

SPRINGFIELD, OHIO, Jan. 28—Stockholders of the Victor Rubber Co. at the annual meeting yesterday elected directors and heard reports showing that the plant is turning out 300 cord tires daily. The normal output is 500 per day. Directors elected are:—Otto Miller, Allard Smith and W. L. Timmons, Cleveland; H. J. Robben, Cincinnati; F. R. Talbott, C. A. Swinehart and H. H. Durr, Springfield.

PREMIER PRESIDENT DIES

KANSAS CITY, Feb. 2—Dr. L. S. Skelton, president of the Premier Motor Corp. of Indianapolis, died here Saturday after a brief illness.

Calendar

SHOWS

Feb. 5-12—Minneapolis, Annual Automobile Show, Minneapolis Automobile Trade Ass'n.

Feb. 7-12—Columbus, National Tractor Show, Columbus Tractor & Implement Club, Ohio State Fair Grounds.

Feb. 7-12—St. Louis, Annual Automobile Show, St. Louis Automobile M'f'rs & Dealers' Ass'n, Robt. E. Lee, Mgr.

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n, Armory, Arthur Fifoot, Mgr.

Feb. 12-19—Kansas City. Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, Secy'.

Feb. 21-26—Salt Lake City, Annual Automobile Show, Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatzky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Feb. 7—Delhi, India, Delhi Motor Show.

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

October—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

CONVENTIONS

May 4-7 — Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

Test Highway to Show Construction Defects

CHICAGO, Jan. 29—A road is being built in Illinois, Federal and State governments co-operating, for the purpose of determining what kind of road to construct to meet present-day traffic conditions. This test road which is well under way now and which will probably be completed early this summer is expected to answer the following questions which are confronting the engineers of to-day:

"What is the economical limit for motor truck loads?

"What is the corresponding limit for the type and thickness of the pavement?

"What is the load-carrying capacity of the standard types of hard-surfaced pavements of varying thicknesses?"

Clifford Older, chief engineer for the state highway department, believes "that the results obtained will give a definite idea of the value of the different types and thicknesses of pavement for carrying truck loads and also will furnish a basis for deciding how heavy pavements should be built and the limits of the loads which should be carried on them."

PAIGE RECORD AUTHENTICATED

NEW YORK, Jan. 31—The American Automobile Assn. has authenticated the record for stock cars established when Ralph Mulford covered a mile straightaway at Daytona in 35.01 seconds in a Paige "6-66" Daytona stock model.

IOWA EXTENDS ROAD WORK

DAVENPORT, IOWA, Jan. 28—Fifteen Iowa counties last year began paving primary roads, according to reports from the highway engineer's office, but this represented only about a ninth of the program road building forces in the state were ready to undertake.

Forty-five miles of hard-surfaced road were completed and 177 miles contracted for, to be completed this season. Two months ago there were ninety-four projects under way in thirty-two counties and these presented paving of 166 miles, gravelling of 203 miles and grading of 913 miles of highway.

Fiat Enters Three Cars in French Grand Prix

PARIS, Jan. 15 (*Special Correspondence*)—Fiat has just entered three cars for the French Grand Prix 183 cu. in. race to be run on July 23, probably at Strasbourg. This is the first appearance of the big Italian firm in an open speed contest since 1914. Drivers selected for these cars are Louis Wagner, who frequently raced for Fiat prior to the war, and the two Italians Minoia and Bordino. The two latter have figured up to the present as mechanicians.

SPAIN TO SHOW TRACTORS

NEW YORK, Feb. 1—An international exhibition of agricultural machinery, including tractor trials, will be held at Lerida, Spain, April 1-10. All machinery for the exhibition will be exempt from Spanish customs duties and exhibitors desiring information should write to the Comite de Organizacion, Exposicion Internacional de Maquinariam Agricola en Lerida, Urgel 187, Barcelona, Spain. The tractor trials will include a four-hour plowing competition, the minimum depth of furrows to be 20 centimeters.

Pennsylvania University Starts Highway Course

PHILADELPHIA, Jan. 31—State, municipal and private engineers have just begun attendance at a special course in highway engineering opened at the University of Pennsylvania. To qualify for the course, the men must have either a degree in engineering, or experienced in highway work.

The class started with seventy-eight members. Included in the number are thirty-six from the Pennsylvania State Highway Bureau, ten from the New York State Highway Bureau, six from the Delaware State Highway Bureau and ten from New England. The men taking the course average from thirty to forty years of age. The course, under the direction of Prof. Milo S. Ketchum, of the civil engineering department of the University, includes among its lecturers many of the most famous road builders of the country. In this connection, on Feb. 7, there will be a conference of highway engineers.

NEW ZEALAND PLANS AIR MAIL

NEW YORK, Jan. 29—New Zealand will establish airplane mail routes along lines proven to be practical by the United States Post Office Department, according to J. B. Murphy, of Timarou, who is in New York. He is interested in an aircraft operating company in Timarou and came to New York for a demonstration of the ten-passenger Liberty-engined Curtiss "Eagle," with a view to utilizing it in a tourist sightseeing service over Mt. Cook. The government is also encouraging civilian aeronautics by the enactment of laws and establishing landing fields.

Trucks and Tractors Discussed at Chicago S. A. E. Meeting

Most of the professional sessions given over to discussion of maintenance and service problems. Truck fleet operation and the application of power to trucks are also considered. 500 attend the dinner.

By J. Edward Schipper

ENGINEERING activities during Chicago show week centered in the S. A. E. meeting. Professional sessions occupied an entire day and were followed by a dinner attended by over 500 members and guests.

The first session was given over to the subject of trucks and the second to maintenance and operation. The morning session included papers by L. L. Scott on steam power applied to a truck; N. J. Ocksreider on engineering analysis applied to truck selling and Capt. J. B. Haney on progress in design of ordnance equipment.

The afternoon session, which took up maintenance and operation, also had a program of three papers. N. J. Smith spoke of truck fleet operation, J. C. Thorpe on tractor service requirements, and T. F. Cullen on designing to facilitate service work. At the banquet H. L. Horning acted as toastmaster. The speakers were: David Beecroft, directing editor of the Class Journal publications and president of the S. A. E.; H. H. Merrick, president Great Lakes Trust Co., and Prof. John Paul Good of the University of Chicago.

The feature of the meeting was the discussion of truck operation maintenance and sales.

N. J. Smith, who is manager of truck maintenance of the Consumers Co., Chicago, spoke of the good results obtained by carrying maintenance to the greatest possible efficiency. The Consumers Co. operates over 150 trucks and by the system used under Smith's jurisdiction every one of these trucks receives a thorough inspection every night. A number of specially drilled men organized into specializing groups take care of the cleaning, lubricating and mechanical upkeep of these vehicles. The trucks in use there, as was brought out in the discussion, average about 1000 miles a month. They are washed every night and after the washing is completed they are checked over and must be satisfactory to the inspector before they are allowed to go out on the next day's work.

By carefully lubricating the trucks and by changing the oil as often as required, an astonishingly low upkeep cost has resulted. While it is true that the overhead of maintenance has somewhat increased by the elaborate care given, the cost of operating the fleet has been materially reduced in the long run and the depreciation of the equipment has been cut down to the limit. A number of questions put to Mr. Smith by the truck men present brought out some interesting information.

For instance, it developed that an average of 10,000 miles is secured on a set of tire chains. This figure does not apply to all classes of work, for in hauling coal it is possible to get an average of 15,000 miles

to the set of chains while in hauling stone or sand the mileage will be considerably shorter.

Regarding the regrinding of cylinders, Mr. Smith stated that he could not lay down any set rule. Some cylinders have run 30,000 miles without regrinding, while others have run shorter or longer than this distance by a very large margin. One of the members inquired regarding the regrinding of crankshafts, to which the speaker replied that he had not reground a crankshaft for four years. He stated that shafts which had been measured after having been in service for this length of time showed less than .002 in. wear.

Another variable factor in maintenance is the friction disk on the clutch. Some have to be refaced in one month while others will run for years. He thought that an average figure would be in the neighborhood of one and one-half or two years.

Smith has a man whose entire time is taken up by fuel and oil research. As a result mileage on fuel and oil has been continually increasing. This is accomplished by absolutely correct setting of carbureter and spark for each truck, by seeing that the proper timing of the valves and their correct setting is not departed from and also by the use of up-to-date devices which would tend to better conditions necessary to the attainment of economy. Crankcase oil, after it has been withdrawn when the oil is changed, is utilized for the lubrication of hoists and for other auxiliary machinery about the garage. Mr. Smith is at present experimenting with reclaimed oil for the cylinder lubrication, but has not as yet arrived at a definite conclusion.

Considerable interest and some amusement was expressed by the hearers to Mr. Smith's frank reply to the question of whether or not he was overloading his trucks. He stated bluntly that he is. He amplified his statement however by saying that the overload was compensated for by insisting that the trucks be never overspeeded. He confessed that the overloads sometimes amount to 30 per cent but said that overspeeding is far more damaging to the truck than overloading, hence the rigid rule against excessive speed.

N. J. Ocksreider, in his talk on engineering analysis applied to truck selling, divided his topics into two heads, first, the analysis of a given market, and second, the ability to analyze the transportation needs of the prospect. As an example of what he meant by proper analysis of the truck market he pointed out that a city district might be divided according to area, and while superficially all of the salesmen were allotted equal territories, the potential market in one division of the district might be far greater than in another. He outlined the necessity for making a careful study of all the factors involved in determining the number of actual prospects and the actual number of trucks required to meet all the transportation problems of any given district. Mr. Ocksreider, by his analysis, made clear the importance of apportioning sales effort and expense according to the possibilities of any definite areas.

The other phase of analysis applied to truck selling is in the use of engineers equipped to enter the establishment of a prospect and to properly analyze the truck equipment necessary to most efficiently handle the transportation problem involved. The factors taken into consideration include not only the number of trucks and their size but the routing, control and maintenance of the vehicle. The man to handle this work will of necessity be a qualified transportation engineer of sufficiently broad business experience to thoroughly grasp the needs of the plant under consideration. Not only must he accurately gage the type of equipment and the number of trucks of each capacity but also their performance characteristics as determined by engine size, wheel size, gear ratio, etc.

One of the most interesting talks of the entire session was that of J. C. Thorpe, a graduate engineer who has been an automobile dealer for several years and lately a tractor dealer. His views on the ethics of salesmanship and the obligations of the factory to the ultimate consumer have been voiced on previous occasions. He summed up his views of the dealer in the following words: "The only man who has a right to be a dealer is the man who sells good merchandise by good merchandising methods and who, having made the sale, remains in the capacity of a consulting expert on the use of the goods."

There has been considerable discussion on who is the best qualified man to be a tractor dealer. Thorpe gave it as his opinion that the best tractor dealer, regardless of whether he formerly sold automobiles, hardware or farm implements, is the man who keeps his tractors sold. The manufacturer should, he said, study the interest of the purchaser through the dealer. He must do it through the dealer because of the proximity of the dealer and his acquaintance with the purchaser. In doing this the manufacturer gradually develops his good will.

It takes years of effort to develop the desired degree of public good will and it may be destroyed entirely by one bad step. As an example of the method necessary for the manufacturer to develop this good Thorpe cited the policy employed by Marshall Field & Co., which is embodied in the expression, "The customer is always right."

In many instances the farmer buys a tractor by selecting the dealer rather than the machine. This, he said, should not be so. The matter of service, of course, enters into the relations between the tractor dealer and his customers to a marked degree, but it must be remembered that there is no such thing as free service. Some one must pay and it must be the customer unless the dealer is to go out of business. We must reach a definite understanding of the meaning of the word service and we will not do so until there is proper co-ordination between the engineering and merchandising departments of our factories. Good service is the result of cooperation between the dealer, factory and owner during the life of the machine to the end that the owner shall receive continuous use at reasonable cost.

Age of the tractor, Thorpe contended, makes no difference as regards the rendering of service. Neither should it make any difference whether the machine is in the hands of the original purchaser or not. In order for the dealer to give the proper quality of service he must be amply supplied with parts and the necessary technical knowledge to perform the repairs he is called upon to make. An incompetent dealer will discredit a good design and set at naught all the care and study given to the original design of the machine.

Mr. Thorpe stated that he did not look with favor on the practice of replacing parts at shipping and labor cost to the customer where these replacements are due to defective material, even though the ninety-day guarantee period had elapsed.

In discussing the faults of design common to tractors, Mr. Thorpe brought up the point that probably the most common defect is the absolute neglect of attention to the comfort of the operator. He said that it is absurd to expect an operator to sit with any comfort in a cast iron seat for 10 or 12 hours at a stretch. He pointed out the remarkable sales value in the tractor in which this point has been given attention. No one but the farmer can appreciate the courage necessary to get

up at 4 o'clock the morning after spending a 12-hour day in a seat upholstered only with black enamel.

Another feature of design which the speaker stated is overlooked is that of supplementary tools. He stated that because the tractor is considered only as a plowing machine by a large percentage of operators the average use is only 35 days per year. Proper supplementary tools would make the tractor available for many more tasks and for longer periods during the year, bringing the average up to 65 to 70 days. This would spread the overhead and reduce the operating expense, making the tractor appeal to the farmer as a better investment than it does to-day.

One point which the speaker brought out is applicable to the truck dealer as well as to the tractor dealer. The data the dealer has available should be interpreted to the prospect in terms of his problems. He said there is a woeful lack of the right kind of data. Where tests have been made they are of a highly technical character and the results have seldom been expressed in such a way that the customer can apply the information to his own particular problems.

T. F. Cullen spoke on the need for greater service accessibility in car design. He made the point that greater accessibility for service work also tends to lengthen the life of a car, as it makes service work easier to perform, less costly and therefore more likely to be undertaken at the first indication of trouble. He said the supply of skilled mechanics is never large enough to fill the demand. Any improvement, such as better service accessibility, which cuts down the time per operation in service work without impairing the car's subsequent efficiency, has exactly the same effect as increasing the number of skilled mechanics. With more accessible cars, service stations can turn out more work with fewer mechanics and therefore make bigger profits, or show a profit where they now show a loss, as many of them do. The dealer's success, both in selling cars and in servicing them, is just as essential to the factory as the owner's satisfaction.

More and more cars are sold each succeeding year to replace worn-out vehicles. Service reputation, based on the cars now in use, is rapidly becoming the predominating factor in these resales. Therefore anything that can be done to improve service work will make resales easier.

As an example of the results which could be secured by improving service accessibility, it is only necessary to recall that there are over 8,000,000 cars in use to-day, and improved design which would reduce the time necessary for service work to the extent of only 2 hr. per car per year, would save the owners over $15,000,000 per year on upkeep.

The paper by Louis L. Scott, chief engineer of the Standard Engineering Co., St. Louis, on the application of steam power to an automotive truck, will be reviewed in a later issue.

Tax on Automobiles Is a Tax on a Utility

THERE still remains in the public mind a vague belief that the passenger automobile can truthfully be called a "pleasure" car—in other words, that it is to a large extent a luxury. There even remains the feeling that the automotive truck is an expensive form of transportation and should be discouraged. These beliefs, erroneous as they are, have had a decided effect upon the sentiments both of bankers and of the buying public. Those sentiments are responsible for the effort now being urged before Congress to impose greatly increased taxes upon both cars and trucks.

It seems impossible that any policy so suicidal to the prosperity of the whole country as well as one so unjust to a great industry can be adopted. It is surprising that any argument is necessary in regard to the truck. The Government itself has records showing that the postal express lines running over distances up to 248 miles from Maryland into Washington resulted in selling farm products to consumers at something like 43 per cent less than the normal market prices. Other statistics show that truck haulage can often produce a saving over rail transportation up to distances around 200 miles. The advantages of truck transportation for shorter distances, especially in cities, have been proved by hundreds of thousands of truck owners. Even a slight investigation would show these services conclusively.

The fact that the passenger car is a factor of equal economic importance is not so easily demonstrated by statistics and this perhaps accounts for the feeling that the passenger car is a luxury, although the car passed out of that condition at least six years ago. A recent questionnaire sent out by the National Automobile Chamber of Commerce showed that 90 per cent of all passenger cars are used more or less for business purposes, and that more than two-thirds of the total mileage run by passenger cars is for business. So the utmost that can be charged against the passenger car to-day is that it gives pleasure after it has done a full day's work. The questionnaire brought out an even more startling fact that the average motor car owner increases his earning capacity about 57 per cent through its use. The value to the farmer has been shown time and again, and altogether no doubt can remain in the mind of any candid man who investigates that the automobile is far more than paying its own way to-day. In addition, of course, are the great intangible values that the automobile is giving—its contribution to comfort, pleasure and health.—From J. G. Vincent's address at Annual S. A. E. Meeting.

Airplane Taxi Fares

AN aerial taxicab in London costs approximately the same as an earthbound taxi in New York, according to Prof. E. P. Warner of the Massachusetts Institute of Technology and the National Advisory Committee for Aeronautics, in his paper, "Commercial Aviation in Europe," read before the Commercial Aviation Session of the Annual Meeting of the Society of Automotive Engineers.

The charge in England for an aerial taxi is 2s. 6d., or 44 cents for two persons per mile. This fare is only two and one-half times as large as that for an ordinary taxi in London, and it costs approximately the same amount to travel by airplane in England as by taxicab in New York. The actual costs of air travel in Europe have shown a tendency to steady reduction.

During the first eleven months of commercial flying between England and the Continent there was a total of twenty-four accidents, but only one passenger was killed. This works out roughly as one death for every 67,000 passengers, or one fatality for 1,640,000 passenger miles.

No European country operates its own mail planes, as has been the practice here. The mail operating companies are privately conducted and receive a fixed fee from the government.

Vauxhall Producing Two Chassis Types

That for general purposes has 130 in. wheelbase and a 3¾ x 5½ engine. The sporting type has 114 in. wheelbase but uses a larger engine, is lighter and has a higher gear ratio.

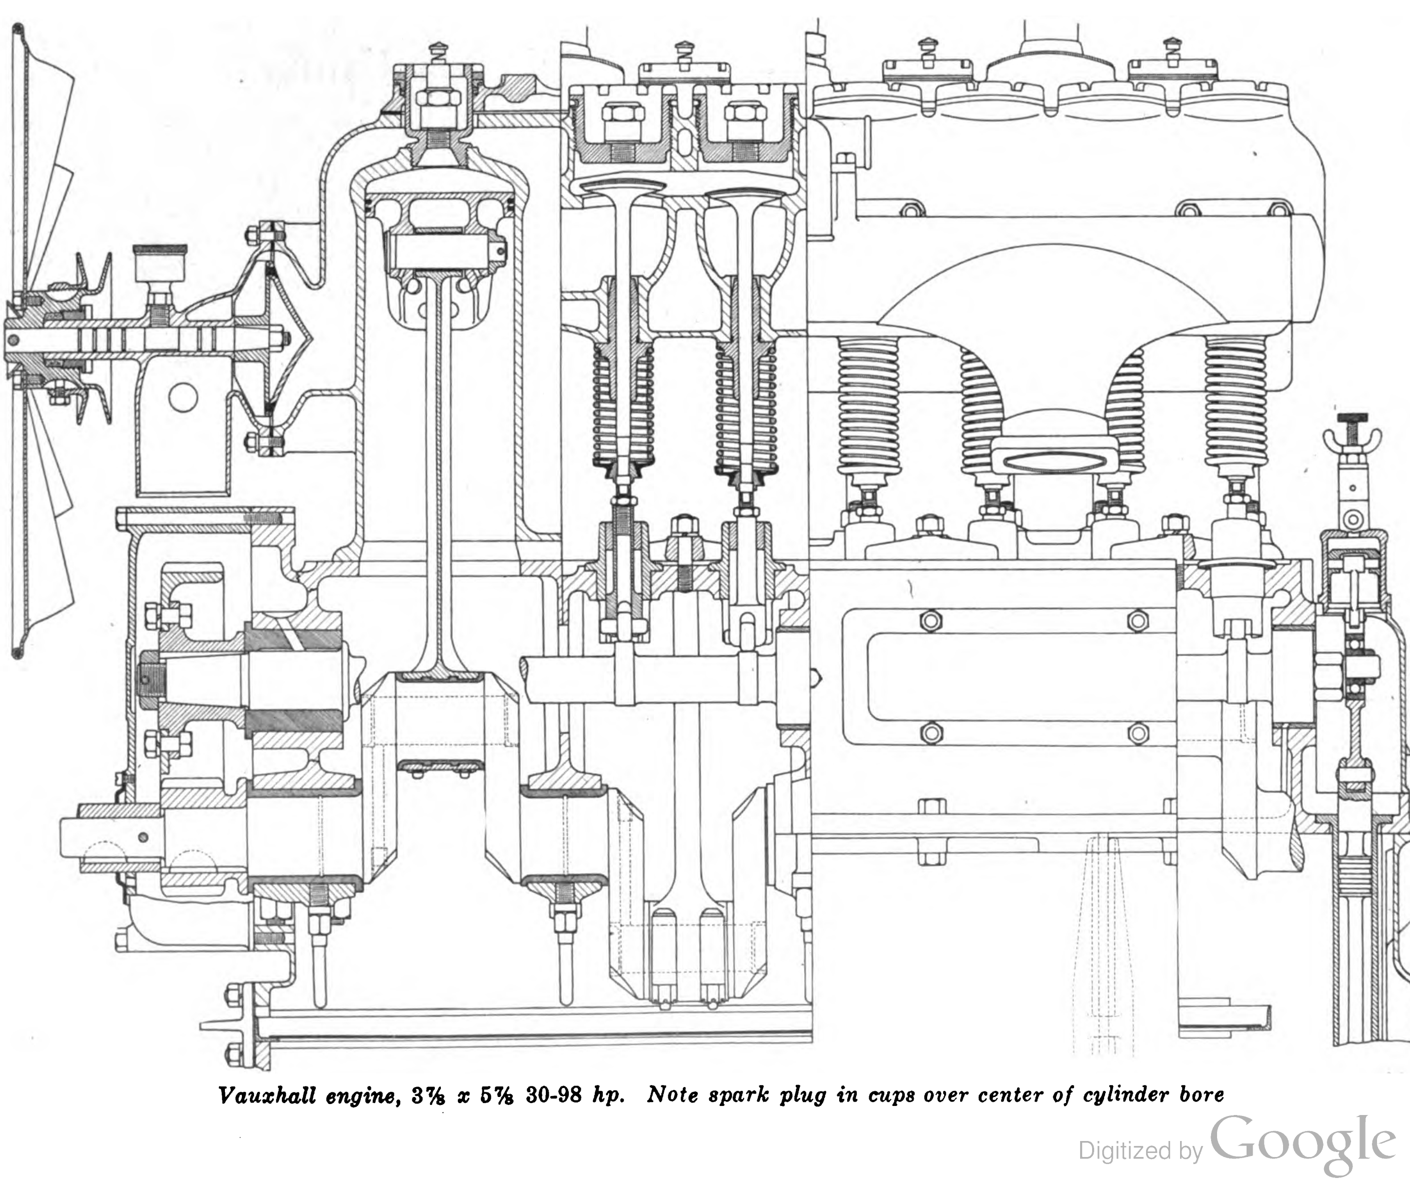
By M. W. Bourdon

TWO types of Vauxhall cars are to be made this season, as in past years. The smaller, termed the 25 hp. model, has a bore of 95 mm. and a stroke of 140 mm. (3¾ x 5½ in.). The block cast cylinders have L heads with the valves considerably inclined from the vertical. The cast iron pistons carry three rings and have the wrist pins fixed in their bosses. Pressure lubrication is employed. Oil is forced through the hollow crankshaft by a plunger pump operated from an eccentric pin at the rear end of the camshaft through a link having a ball-bearing on the pin. An upward extending link or connecting rod operates the piston of an air pump for the pressure feed fuel system.

Water circulation is of the assisted thermosyphon type, the belt driven fan shaft having at its rear end the impeller of a water accelerator enclosed at the front of the cylinder block. Magneto ignition is standard, the magneto being driven directly from the chain distribution on the left of the crankcase. The carbureter, located on the right, is bolted to an induction branch integral with the cylinder block on that side and leading by cored passages to the valve ports on the left, where the separate exhaust manifold is located.

A feature of both Vauxhall engines is the filter tray of gauze, which forms a false bottom to the crankcase, and can be withdrawn from the front below the cross member by removing the six nuts which hold the flanged front end to the front face of the oil sump.

Engine and gear-box are separately mounted on a subframe. The multi-disk clutch is connected to the four-speed gear-set by a shaft and flexible coupling. Right-hand control is employed and to the transmission is fitted



Vauxhall engine, 3⅞ x 5⅞ 30-98 hp. Note spark plug in cups over center of cylinder bore

an expanding type brake. An open propeller shaft, with star and block joints at front and rear ends respectively, conveys the drive to the spiral bevel gearing with 3.6 to 1 ratio in the rear back axle. Semi-elliptic springs are used, but the torque and drive are taken by a triangulated tubular torque member attached to the axle casing center at the rear and to a tubular cross member at the front. This chassis, which has a wheelbase of 130 in., has recently been reduced in price to $5,000, a reduction of approximately $1,000.

The second Vauxhall chassis is termed 30-98 hp. and has a bore and stroke of 3⅞ x 5⅞ in. As with the 25 hp., the four cylinders are block cast with L heads, but a distinct variation occurs in the position of the spark plug, which is mounted immediately over the center of the cylinder bore in a recessed cap, passing through a cored hole in the cylinder jacket and cylinder head. High lift cams with valves of 2¼ in. diameter, stiffer springs and slipper type aluminum pistons with two rings are other features wherein the larger model differs from the other. It has a five-bearing hollow crankshaft arranged for pressure lubrication, with the same type of oil and air pumps as in the case of the 25 hp. model.

There is very little difference, except in the points mentioned, between the two chassis in general construction, though the larger one has a shorter wheelbase (114 in. as against 130 in.) and straight bevel final drive instead of the spiral bevel. This chassis is also considerably lighter than the other, viz., 2650 lb. as compared with 2900 lb.; naturally, then, it has a higher gear ratio, viz., 3 to 1. It is made primarily for light sporting type four-passenger bodies and not for general purposes, as is the 25 hp. chassis. The sporting type shown at Olympia was fitted with a body of the clover leaf pattern seating three passengers and having a very light superstructure.

This chassis has also been subject to a price reduction of approximately $1,000, now being sold at $6,250.

Valuable Work Done by the Forest Products Laboratory

ORGANIZED research to-day is becoming more and more of a factor in progressive business. There is a decided advantage from the standpoint of the wood-using industries in having available a neutral research organization, such as the Forest Products Laboratory, which is not only the foremost of its kind in existence, but which is well organized, efficiently operated, equipped already with a large knowledge of the basic properties of wood, and with facilities for advancing research economically.

The laboratory's activities have touched practically all wood-using industries and have advanced in one way or another their knowledge of wood and their methods of using it. Every thousand feet of lumber (88 1/3 cu. ft.) made available through better utilization relieves the drain upon the forest by about 250 cu. ft. This is because under present utilization three cubic feet of wood must be grown in the forest for each cubic foot of finished lumber.

The work of the laboratory is concentrated upon devising means for saving as many of these cubic feet as possible, and upon securing the adoption of the improved methods by the industries. Almost invariably, the methods which have been developed have resulted, not only in an actual saving of wood, but also in a better or cheaper product delivered to the consumer.

Very definite progress has been made by the laboratory along many lines of conservation and utilization, and also along other lines, such as in the development of water-resistant glues.

The function of the Forest Products Laboratory is, in the main, two-fold—first, to carry on research and obtain authoritative information concerning wood and other forest products, and second, to make this information available, in usable form, to the industries and to the general public.

During the ten years of its existence the laboratory has made much progress in connection with items listed below. Aircraft parts boxing, crating, packing, chemistry of wood, decay and decay prevention, ethyl alcohol from wood waste, glues for wood, grading lumber, grading structural timbers, hardwood and softwood distillation, identification of wood, kiln drying and air seasoning, mechanical properties of wood, structure of wood, needle and leaf oils, preservation of wood, pulp and paper, steam bending, veneers and plywood, wood finishes.

As illustrations of the kind of work carried out at the laboratory, a few typical accomplishments are presented here.

1. The art of testing containers has been developed at the laboratory in the past five years. During that period much has been discovered concerning the proper construction of boxes and help has been given to various associations and to many individual manufacturers and users of boxes in the most efficient and economical methods of design and construction. Much progress has also been made in the design of crates for machinery. To make the knowledge gained more effective, and in response to insistent demands from box makers, packers, and shippers, courses of instruction in box and crate design are given periodically at the laboratory.

2. The experiments conducted at the laboratory during the past nine years have developed kiln drying from a haphazard, wasteful and thoroughly unsatisfactory rule-of-thumb process to a reasonably precise art. Methods and drying schedules have been developed for the drying of most commercial woods, ranging from oak vehicle stock, green from the saw, to one-inch pine and fir. Numerous patents have been taken out on apparatus for artificial seasoning, and two types of dry kiln have been developed to a state of high efficiency.

The most spectacular, and also the most urgent, applications of this drying work were the drying of gunstocks, artillery stock, and airplane stock during the war. This was done with thorough success in many kilns of the type developed at the laboratory, and according to specifications and schedules prepared by the laboratory. Courses of instruction in kiln drying are given each month and are proving of great help to the industry.

3. Search for substitute woods to replace the rapidly vanishing spruce and other commonly used pulpwoods has been going on steadily for many years.

4. All the important American woods, in commercial use, have been tested and their mechanical properties determined, and made available to the industries.

5. Investigations into the efficiency of many wood preservatives and into the best way to impregnate the important commercial woods of the United States have done much to advance the art of wood preservation.

Editorial on Doubling Fuel Mileage Commended by Prominent Engineers

Effort to arouse automotive industry to need and possibilities of greatly increasing miles per gallon of fuel meets with favorable response. Some conservative engineers consider radical changes desirable.

THE editorial bearing the title, Can We Double Mileage Per Gallon of Fuel? which appeared in AUTOMOTIVE INDUSTRIES for Jan. 27, has resulted in comment which indicates that many engineers agree with the view that it is possible to greatly increase the number of miles per gallon that cars travel under present conditions, and some of them state that radical changes must be made. While nearly all the comment received indicates that the basic cause of inefficiency of present day engines as now applied is recognized and must, as we pointed out, be remedied before very material increase in efficiency can be attained, there is naturally much difference of opinion as to the methods by which the desired result can best be attained. Some consider rather radical changes desirable while others point to lack of refinement in the average present day engine as the first problem to be attacked. Some doubt the possibility of attaining double the mileage now secured, at least in the case of cars which are now performing well above the average, but others think such an increase within the realm of possibilities.

Some of the comment we have received deals, primarily, with the methods we mentioned as being promising, one or two taking the view that the evidence to date in favor of these methods is not sufficient to justify a prediction of their general application. Our intention is not, of course, to "boost" any one method of securing the desired result, and we have tried to make it clear that much careful research is necessary before any method can hope to see general adoption. Our purpose was, first, to point out the inherent defects in present practice; second, to show that there are possibilities of material improvement, and third, to urge upon those in a position to develop these possibilities the importance of supporting and prosecuting research which will enable the industry to realize the benefits which are within its reach.

We propose to follow out this policy and give space to descriptions of any methods which seem to us to promise the desired results, as well as to reports of research work and constructive comment which lead in this direction. It is our intention to hammer away at the fuel problem until concrete results are attained, or at least until it becomes evident that such results are not attainable or that the automotive industry is too little interested to make the effort worth while. We bespeak the co-operation of those who we know have this matter at heart, but will, of course, welcome constructive criticism.

The following extracts from letters referring to the above-mentioned editorial will, we believe, prove interesting and instructive. They represent only a fraction of the total number of comments received.—THE EDITOR.

Andrew L. Riker.—I am heartily in accord with the editorial which appeared in AUTOMOTIVE INDUSTRIES of Jan. 27, as I believe that something must be done to make the automobile engine more efficient. I have had this in mind for some years past, having designed an engine some 18 years ago, operating on constant pressure cycles, as against the constant volume cycle, and cannot help but feel that we must abandon our old ideas and secure a new system of using fuel, which will permit us to have at least a fair efficiency on part load, as that is about the condition we are operating under practically 90 per cent of the time.

Harry L. Horning.—Accept my thanks and compliments for the very well-put editorial in your issue of the 27th. It certainly hits the nail on the head.

Percival S. Tice.—I have found your editorial of very great interest.

We have been working with a method of localized carburetion, which has given some very interesting results. At the same time it seems to be proven that the full advantage in economy of this method of supplying an engine with charge, cannot be realized unless the compression ratio is carried quite high—that is to say, so high as to be practically unusable in the ordinary class of automotive equipment.

It must be granted that there are very material improvements in thermal efficiency at small loads when full charges of air are taken into the cylinder under all conditions of load, but it must not be overlooked that to a very great extent the improvement in efficiency under small load conditions follows from the great reduction in charge dilution in such an engine, rather than from the increased compression pressure. In the ordinary engine, operating at about one-tenth load the charge dilution amounts to approximately 60 per cent by weight, while when full quantity of air is pumped the dilution will run from 4 to 6 per cent.

It is the writer's opinion that a more flexible and generally usable engine would result with localized fuel charges if it should be found possible to obviate this excessive dilution with products of previous combustion, and at the same time not very materially alter the compression pressures now obtaining over the load range.

A. L. Nelson.—I was very glad indeed to see the editorial comment on doubling the mileage per gallon on fuel which is published in the Jan. 27 issue.

I believe that the editorial is along the right line and that it is very commendable to urge engineers on at the

present time in order that they put forth their best efforts to produce engines and cars which will give us a much better efficiency than we are getting to-day.

It is also very apparent that we have to make more than an ordinary change in the present time equipment used, and it is surprising the many schemes which appear very feasible that are available when one looks at the problem with a view of seeing what can be done. I might add that we are making some analyses now which appear to offer perhaps 100 per cent increase in mileage without departing very far from standard construction of to-day.

I wish to personally thank you for the efforts you are making to get the problem before the engineers in the industry.

C. A. Norman.—I was very glad to read the editorial on improved fuel economy in AUTOMOTIVE INDUSTRIES for Jan. 27. It is certainly highly commendable for you to take this matter up and urge its careful consideration on engineers and manufacturers.

It may perhaps be of some interest to point out that the improvement attained (in the type of engine described) would not appear to be due simply to increased compression pressure at reduced load. The compression pressure in the Diesel engine remains constant at all loads, yet the thermal efficiency is actually improved at reduced load, on account of decreased "admission," meaning increased expansion. The improvement due to increased compression pressure is caused directly by the smaller amount of residue remaining to foul the charge and impair ignition; by the lower end temperature of compression due to less heat by the residue and consequent greater temperature and pressure ratio available from combustion; by the reduced cooling losses due to possible lower temperatures with leaner mixtures; finally, and perhaps mainly, by the possibility of securing good ignition with sufficiently high air ratio for complete combustion of the fuel.

I have been trying to discuss all these matters a little more thoroughly in a bulletin of the University Experiment Station, which also will contain my entropy chart. Very naturally, you could not enter upon all these things in an editorial without losing something in force of the main point to be driven home. Nevertheless, in engineering discussions I think that it may be of some value to set forth the detail function of expansion and compression separately in their influence on fuel utilization.

H. C. Dickinson.—The possibilities in the line of designing more efficient automobiles and power systems are almost unlimited. There is probably no question whatever that we could, and probably will, design automobiles capable of giving two or three, or possibly four times the mileage of present designs without any appreciable sacrifice in comfort, convenience or speed. The main possibilities along this line would seem to be: (1) Improvement of the fundamental economy of the power plant; (2) Development of a suitable transmission system which will enable the power plant to operate always at an economical speed and load; (3) Design of vehicles to permit much lighter weight without sacrificing speed and comfort.

Whatever may be the possibilities of improving car design with a view to economy, or even the possibilities of modifying existing engines to improve economy, the fact remains that there are at present in existence some eight to ten million motor vehicles, that these vehicles will be in service for an average of perhaps four years, that they are going to be operated and supplied with fuel as long as fuel is available at any price less than say double the present price, that no substantial modifications are going to be made in the vast majority of these vehicles. If the foregoing statements are true, the existing vehicles alone are destined to consume, before they are worn out, a very large part of all the motor fuel which will be produced from United States petroleum. I believe that the Geological Survey has estimated that the crude oil left in the ground would last about twelve years at the present rate of consumption. If this is the case, the existing cars running for four years would consume about 30 per cent of the total gasoline available from this crude oil by present methods of refining. It might be of interest to make a more definite estimate of this figure. In view of these facts, even if not a single additional uneconomical vehicle were constructed, the problem of fuel conservation in existing vehicles would be of paramount importance. As a matter of fact, millions of additional vehicles will be built substantially on present designs. There is no question, therefore, that the most immediate results in the way of fuel conservation can be secured through improvement in the fuel economy of existing equipment, without the addition of any complicated or expensive devices.

The figures given by the Bureau of Mines, indicating that 25 per cent of the fuel used is not even burned, are probably conservative. Moreover, probably much more than a 25 per cent increase in mileage of the average vehicle could be secured by careful operation alone. Almost any engineer or skilled mechanic can secure a large increase in the mileage of the average vehicle without any sacrifice in performance, and we can no longer afford to dismiss the fact with the simple statement that the fault is all due to the ignorance and carelessness of the average driver. The ten million drivers in this country are average people with average intelligence and are interested in saving fuel. If a saving of 25 per cent to 40 per cent of the fuel bill is as simple as it seems to be in the hands of the engineer, there certainly is a possibility of educating a considerable percentage of these ten million drivers so that they can secure such saving. Is it not worth while for the engineer to first determine precisely how the average driver can improve his mileage and then to proceed to educate the average driver to a point where he can secure this result?

Henry M. Crane.—Of course what you say regarding the necessity of maintaining the highest possible compression at the actual running speeds is absolutely true, and it is equally true that this is a condition almost impossible to obtain in the ordinary type of four-cycle engine. There is evidently, therefore, a possibility of very radical improvement in road mileage per gallon by changing the type of engine. No engineer has the right to overlook this possibility. On the other hand, we know that very many cars to-day are being put on the market that would be capable of great improvement in mileage if better design and also better workmanship were used in their construction. I think that the industry as a whole is very lax in its attitude toward such improvement and would like to feel that there is no use of doing much except wait for some revolutionary invention to come along.

I know you say that work should not cease on the development of the present conventional designs, but I am discussing the effect that the general tone of the article had on me and would be sure to have on the men in the industry who are not engineers.

Hugo C. Gibson.—The editorial in AUTOMOTIVE INDUSTRIES is very interesting. I believe that you can do no better service to the automotive industry than to harp and harp along these lines until the manufacturers are

forced into a position of attacking this problem wholeheartedly.

We are going right after it, hard. Of course, we have a strong incentive in the absolute necessity for furnishing the public with a quiet engine, and I believe that quietness of operation and economy go very much hand in hand. I never heard of a detonation that was either quiet or economical.

Th present tendency of the automotive industry, practically throughout the world, toward the small high-speed engine is, in my opinion, only justified by such economy as is represented in the low first cost of the apparatus. We all know that the Otto-cycle automotive engine is most economical in consumption at moderate speed—say from 900 to 1400, averaging perhaps 1100 r.p.m.—and that a really serious increase of cost of operation, not only of fuel and oil but a great depreciation of every operative part in the power line, occurs just so soon as we increase the rotative speed of the engine.

European practice is tending more and more toward the use of an increased number of selectable gear ratios which, providing the engine is large enough to permit its use at the economical speed of rotation, is a real step toward economy. This leads us to the question as to whether a four-speed gear driving direct on third, with stepped up fourth or direct on fourth, would be the most desirable. Personally I believe in the direct on third.

It is a fact that no high-speed machinery is quiet, and that noise means wear—even the high-speed electric motor is not quiet and it surely does wear in comparison with low speed. Friction horsepower curves show us clearly enough that the amount of gasoline used up in turning the small engine over at a high speed, apart from the amount used to deliver turning effort to the rear wheels of the car, is not in any sense compensated for by the slightly less effort required to propel a similar car, but fitted with a few more pounds weight in the engine.

Taking all the above into consideration, you can see why I am in favor of an engine large enough to furnish a reasonable touring speed at an economical r.p.m.

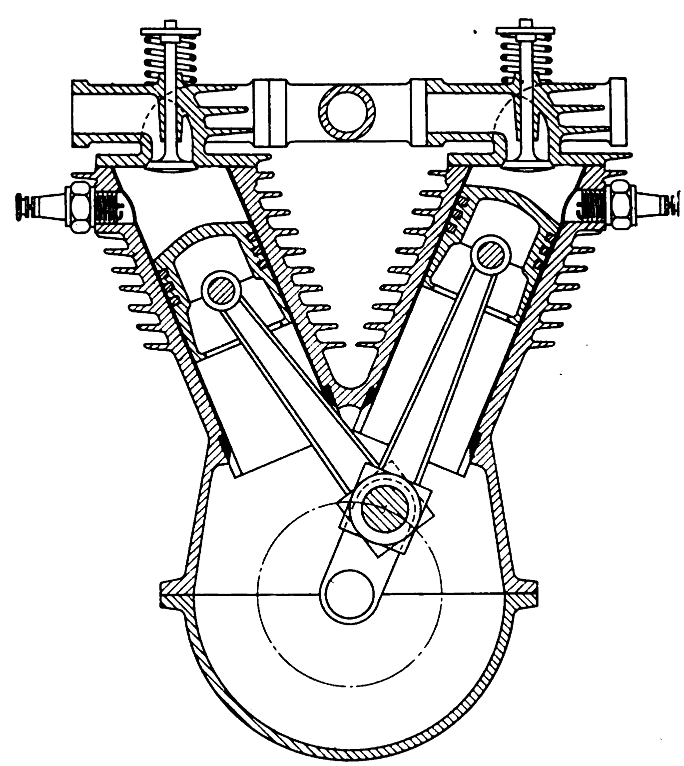
I believe with you that it is time for radical improvement and it is possible that this improvement may lie in raising the physical duty per piston—in other words, making a smaller boiler do the same work at the same speed of operation.

Otto M. Burkhardt.—I am very much interested in the editorial in AUTOMOTIVE INDUSTRIES of Jan. 27, 1921. In this it is stated that a prominent manufacturer has increased the fuel efficiency by admitting pure air through one of the dual inlet valves and a rich mixture through the other. In consequence the full compression pressure is claimed to be maintained regardless of load. This is truly an ideal, engineers have been hoping to materialize. The most reliable experiments in this direction of which I have knowledge are those by H. R. Ricardo compiled in a paper that was read before the Royal Aeronautical Society of Great Britain. This paper was published very recently in the English paper *Engineering*. Ricardo's success was not nearly as marked as stated in the editorial mentioned above, and what is more important Ricardo's success in saving fuel entirely depended on his success of keeping the mixture in strata.

Stratification of the charge it must be admitted in one way conflicts with high efficiency because strata preclude turbulence and turbulence as we know is all important to secure reasonably fast combustion. There are, of course, other difficulties such as uneven distribution of the charge in a long manifold. This condition is accentuated if only one part of the cylinder charge is taken through the carbureter.

An Aluminum Motorcycle Engine

A NEW type of motorcycle engine, which should be very light in weight, is described in *The Motorwagen*. It is of the 2-cylinder "V" type, and the two cylinders are cast together with the top half of the crankcase of aluminum. Cylinder liners of cast iron are set into the mold, and therefore do not have to be fitted. The cylinder heads are separate castings, and the upper surfaces of the cylinders are parallel with the lower surface of the upper half of the crankcase, hence both surfaces can be machined in a single operation. Making the cylinder heads separate obviates the necessity for valve cages. It appears to be the intention to use a ground joint for the cylinder heads, and no gaskets. The valves are arranged perpendicular to the cylinder head joints. The carburetor can be conveniently attached to a short, straight length of pipe between the two cylinder heads. Aside from the inclined cylinder bores, an arrangement which, of course, cannot be avoided, in a V type motor, all inclined surfaces have been eliminated, so that a casting can be machined on any suitable tool without special fixtures. Even the bosses for the spark plugs are arranged horizontally. In small engines the location of the spark plug bosses usually causes the designer considerable difficulty, but the problem has here been solved in a rather skilful manner.



Motorcycle engine with cylinders and upper half of crankcase cast in one piece

A CCORDING to G. C. Loening, the world war hindered rather than helped the development of commercial aviation, due to the fact that many interested in aeronautics have learned to think in terms of war machines rather than of types better suited to commercial work.

Cast Aluminum Instrument Boards in Wider Use

Are applied to most high-priced chassis of British and Continental make and, in simplified construction, to cars of moderate price. The all-metal board is smart in appearance and very workmanlike in arrangement.

By M. W. Bourdon

THE practice of using cast aluminum for dashboards and instrument boards, which first became pronounced at the Paris Salon of 1919, is spreading appreciably on European cars, and this form of construction appeared at the London show on cars of quite low power and on others of medium price, as well as on the high-grade jobs. Cast aluminum unquestionably makes a more workmanlike arrangement, though objections are raised against it in that when sand-blasted it shows up dirty finger marks very prominently, and when polished it forms another item to keep clean if its smart appearance is to be maintained. A smooth but dull finish would seem to be the best.

A simple form is shown in Fig. 1, the Vermorel, but here the dashboard itself is of wood with two latticed brackets of channel section carrying the separate aluminum instrument board and continued below to support the sloping front footboard. It will be noticed that a bracket extending from the right hand side serves as an additional support for the steering column, an unusual feature, but one which might with advantage be more widely adopted, for steering columns on many cars of all nationalities are prone to vibrate appreciably.

A more substantial construction is that of the Star, made by a firm usually inclined to be very conservative and one of the last it was imagined would adopt such an up-to-date construction. The photograph (Fig. 2) is almost self-explanatory, the only feature worthy of special mention being the pivoting of the throttle pedal on the aluminum "ramp" (sloping floorboard). The pedal consists of a curved plate with a tongue projecting down through a slot in the "board," the bottom end of this tongue abutting the flat surface of a lever linked to the carbureter and secured independently of the board. Thus the latter can be lifted clear with the pedal without breaking any joint in the throttle connections. The dashboard is separate from the ramp brackets, its foot being bolted to the top of the latter.

Another fairly simple construction is the D.F.P. (Fig. 3), but this does not give the idea of stability which should be a feature of cast aluminum boards; the dashboard, for instance, needs support from the cowl paneling, whereas, obviously, the reverse condition should apply. The Charron Laycock arrangement (Fig. 4) is far better in this respect, for the dashboard is a box-like casting with its rear face brought well back to cover the ramp. This car is one of quite small dimensions. It has a four-cylinder engine of but 2 9/16 x 4 5/16 in. and sell at $3,000 with a two-seated body.

The Brasier design (Figs. 5 and 6) is also of box form, but this differs considerably in that the space between instrument board and dashboard is enclosed below, the parts and wiring within being accessible, when the cowl has been fitted, only by removing the panels of the dashboard. This is an unnecessarily involved arrangement, as one of the illustrations makes clear. It consists of a number of separate castings with detachable panels and filling-in pieces of specially shaped sheet.

The Straker-Squire construction is unique. As seen in Fig. 7, the unit cast dashboard and ramp support the instrument board by a tubular cast bracket, which contains all the wires and other connections to the instruments. The Klaxon horn is so placed that the passenger's feet may cause damage to the terminals, and where it is somewhat inaccessible when adjustment is required—points which should not be overlooked if this location is selected.

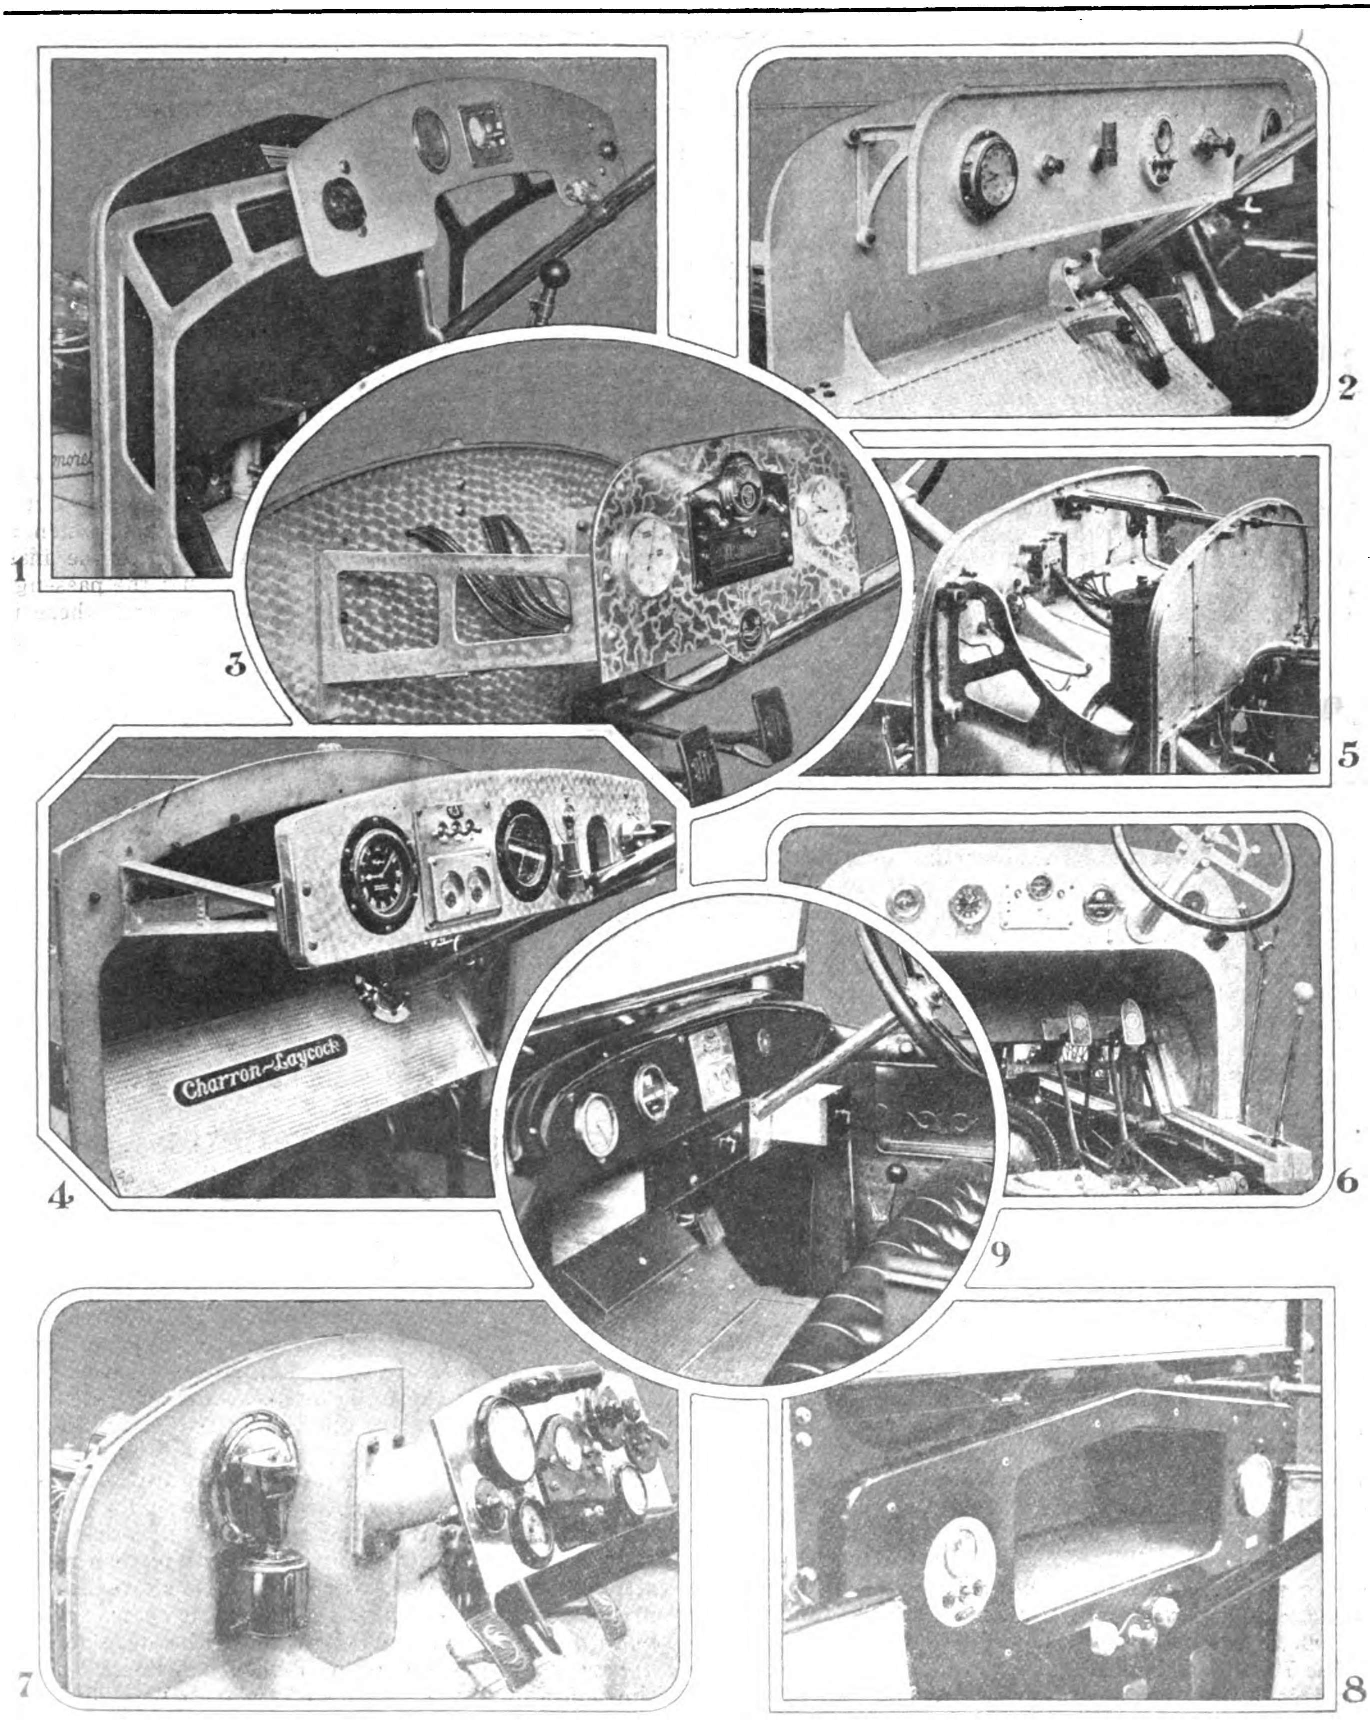
But by no means have the majority of British car manufacturers adopted the aluminum construction. Wolseley, for example, has an instrument board of polished mahogany depending from the cowl but, although the fuel tank is carried at the rear, no attempt is made to utilize the space in front thus made available for other purposes. Standard cars have a roomy enclosed shelf (Fig. 8) at the center for small parcels, gloves, etc., while Humbers (Fig. 9) provide a deep cupboard and a couple of drawers 14 in. long, all these finding space under the actual instrument board and in no way incommoding the occupants of the front seat—they are a distinct advantage and might well be used whenever space for them is available.

Developing a Magnetic Test for Twist Drills

THE Bureau of Standards is taking part in a co-operative investigation by a committee of the American Society for Testing Materials on the testing of twist drills by magnetic analysis. The steel has been specially prepared by one member of the committee and tested for homogeneity by a magnetic method at the Bureau. The drills are to be manufactured from this steel by another member of the committee under carefully controlled conditions, after which they will be tested again magnetically by various members of the committee. Following the magnetic tests, the drills will be returned to the manufacturer, who is to give them a thorough mechanical test. The committee will then meet and atttempt to correlate the mechanical performance of the drills with the results of the magnetic tests. The ultimate object of this investigation is the development of apparatus which can be used in a commercial way for the non-destructive testing of twist drills. The special apparatus for this work is in process of construction at the Bureau.

Types of Instrument Boards Used on British Chassis

(Note extensive use of cast aluminum)



Mechanical Requirements for Trailer Progress

The use of trailers began long before the development of the motor truck; railway trains utilize the principle. Certain mechanical changes are necessary, however, for the progressive development of the trailer in connection with motor driven vehicles. This article discusses this important question.

By Marius C. Krarup

UNTIL twenty years ago nearly all loads in transportation work, on land, were hauled in vehicles trailing after the power unit, unless the loads were very small, the roads very rough and tortuous or primitive customs prevailed. Elephants, camels, llamas, burros, pack mules and saddle horses, all combined, did not figure big in tons or miles as against railway trains and the standard combinations of horses and wagons. Then came the automobile and the motor truck, with their high speeds, and temporarily broke up the trailing system for transportation on common roads, while the tractor continued it for the slowest forms of work only.

There never was any much better reason for abandoning the trailing system for fast work than technical or industrial difficulty in getting all features in transportation by engine power perfected at the same time and quickly enough for satisfying the public demand.

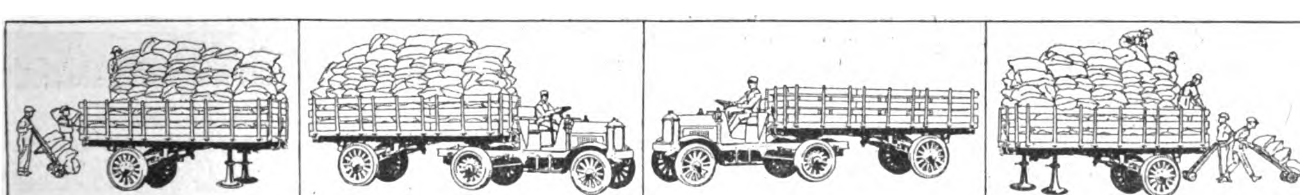
Motor trucks have come as an avalanche, rather than a development, as all can now see by looking backward over the last few years, and the almost abrupt transition to new methods would be more marvelous than anything that is real can be, if there were not many things in the use of trucks still to be adjusted to the great variety of working conditions. The orderly reintroduction of the trailer system, changed as much as necessary for reconciling it with the peculiarities of engine power, as well as modern production and marketing methods, is naturally among the first and most important steps toward improved adjustment to the realities, and has already been widely accepted as indispensable for strict and competitive economy in many lines of business.

Terminology of the Industry

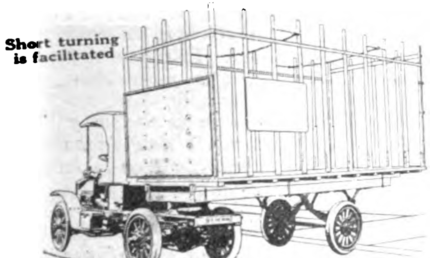
There are, perhaps, 50,000 trailers in use now in the United States, not counting railway cars or the working machines pulled by the tractors. The word "trailer" has, in fact, already become specialized in its sense, so as to refer particularly to separate structures intended for carrying loads in connection with automobiles, motor trucks or tractors. We speak of "four-wheeled trailers," "two-wheeled trailers," "semi-trailers" and "pole trailers." The phraseology is awkward as yet. Terms sounding more natural and businesslike may be found and adopted.

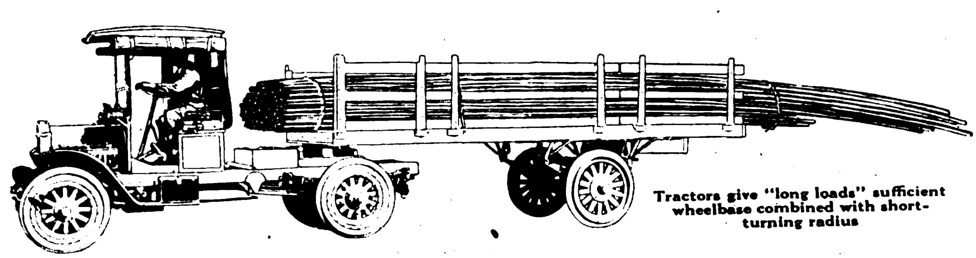
Such words as trailer, trailcart, loader or loadcart and pole-dolly or dolly—for designating the same types in the same order as before—might be found preferable. The word "dolly" is already widely used, though usually with a prefix indicating the purpose of its employment, as lumber-dolly, timber-dolly, pipe-dolly. The latter is used much in the oil regions.

The term "tractor-truck" is sometimes used to denote the shortened truck or light tractor used for hauling a semi-trailer. Traction-cab or cab would be more accu-

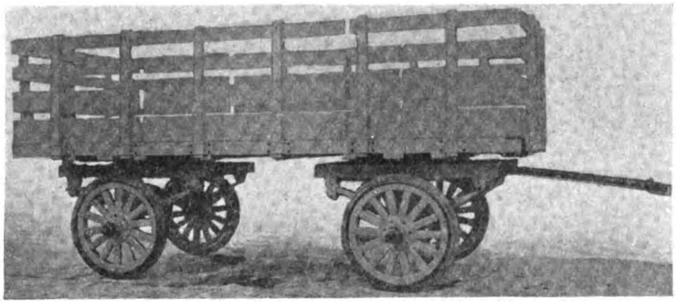


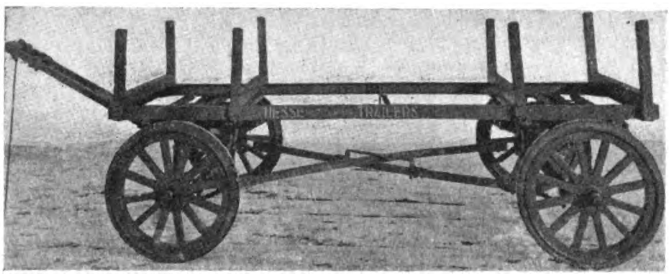
While one Trailer is being loaded— —the Tractor is hauling a loaded Trailer— —or returning with an empty Trailer— —while another Trailer is being unloaded.





(Above) Some operative advantages of the trailer system. (Below) Shows the short turn, the ease of maneuvering in tight places, and the suitability for long loads





(Above) Reversible four-wheel trailer made with two-wheel-and-axle assemblies turning on fifth-wheels under frame carrying body. In towing, the rear one is locked. In backing the front one may be locked. (Below) One manufacturer employs cross-connected axles and two fifth-wheels for a four-wheel trailer, which can be reversible

rate and handier. But in the following the current terms must generally be used.

Effect of Competition

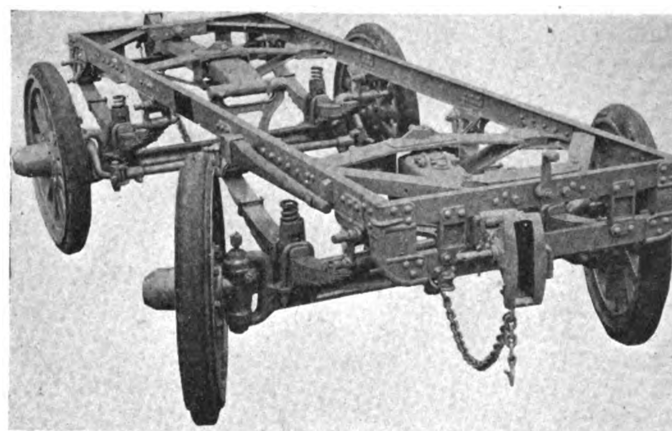
In order to perceive easily the reasons for special construction features in modern trailers it may be useful to note first the evident reasons for that temporary abandonment of the trailing system which has been witnessed. It was possible to give the motor truck a load capacity comparing fairly well with that of the draft truck. But it had no advantage on this point, and it became soon an article of faith that the merits of the motor truck were due to its speed, its capacity for sustained work and the extension of the business zone following the increased daily mileage.

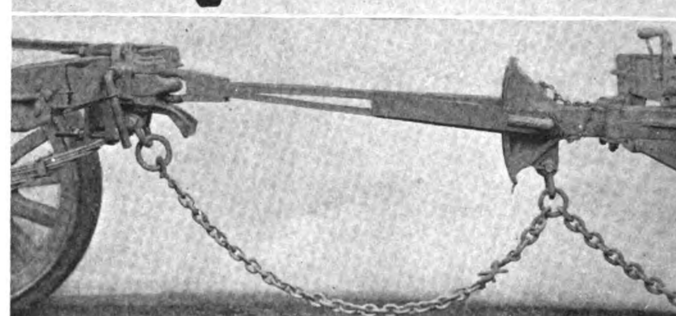
These advantages seemed sufficient so long as the motor truck competed mainly with its predecessor. We humans are modest in our demands if it is not evident that we can get more by insisting. Then there was the traction problem; tires and differential gears were imperfect, and too frequently the motor truck was in trouble taking care of its own propulsion. If it was found in practice that a certain large apparent surplus of engine power was required for the dependable operation of a truck, why would it not eventually be found that a corresponding and larger surplus would be required for operating with the larger load of a truck with a trailer? The answer was not at that time as clear as it is now. Furthermore, couplings suitable for motor truck speeds and short turning angles had not been devised. Neither could they be copied from railway practice, where short turns do not occur.

But in the course of a few years, when motor trucks became so common that they competed in the same lines of business, it was natural to look around for new advantages in economy and operation. The employment of trailers, when that point was reached, presented the conspicuous inducements of an old and familiar expedient and one whose adoption did not call for reconstruction of the expensive motor unit. All other methods that might be contemplated belonged in the realms of radical and dubious engineering—referring to such possibilities as are represented in the heavy steam lorries of England or the introduction of tractors for city commerce. They spelled heavy investments and postponed results. The rejuvenated trailer system, on the other hand, could be inaugurated by the owner and user of motor trucks at small initial expense, involved few delays and could be extended in the measure as it proved itself profitable.

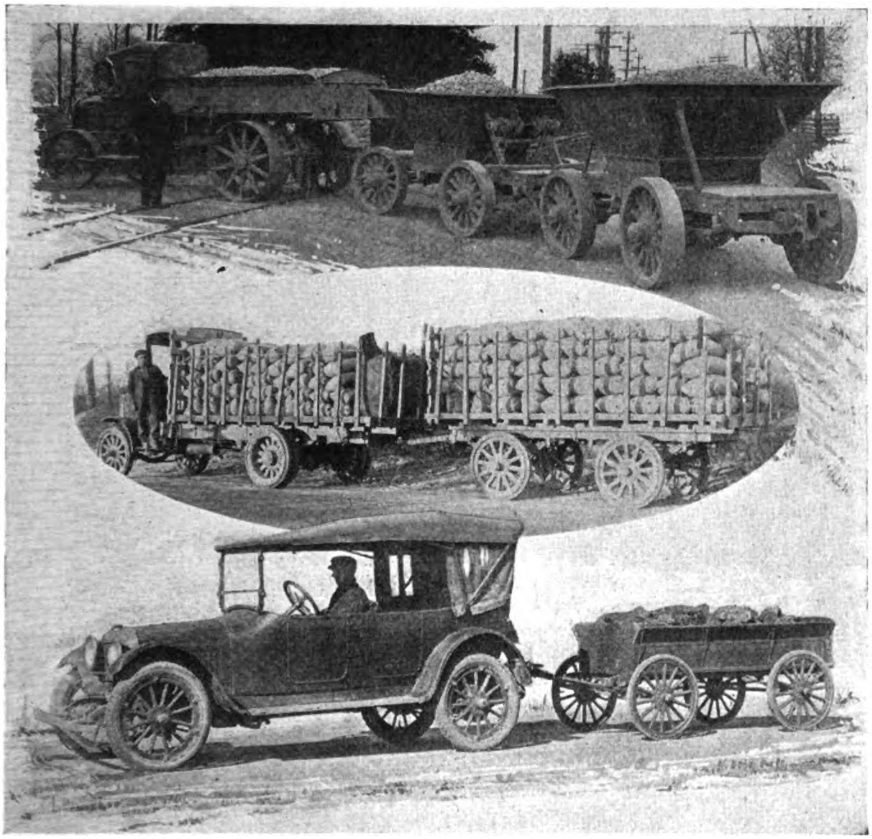
Operating and Upkeep Costs

The inception and rapid growth of the modernized trailer movement is therefore a natural upshot of conditions, logical and inevitable like every other materialistic movement that makes way for itself. The business-man no longer shows his enterprise and intelligence by adopting or resisting it, but by deciding in what particular form he can best make use of it. In some cases he may properly conclude to wait, but if he has a growing business with rush periods or seasons and the local roads are favorable, a trailer equipment of one type or another will usually save him operating and upkeep costs, even in those cases that seem most doubtful at first glance.





(Above) Typical four-wheel trailer chassis of reversible pattern, having hinged yoke at end of swiveled drawbar to compensate for spring action. The yoke is hinged to a horizontal yoke journaled at its rear end to center of transverse steering rod. Drawbar has a bumper head and encloses double-acting draft springs. A drawbar lock, to immobilize rear steering gear in turning or front gear in backing, is released by turning lock crank. To back, the bar at side of frame is inserted in rear drawbar and used as steering lever. (Below) Automatic hitch secured to motor unit in connection with chassis shown above. To couple, the operator raises hand lever and thereby parts the jaws. Then inserts connecting bar into guide and backs motor unit (truck or tractor), tripping the lock. The chains are for safety. To uncouple, the hand lever is raised, the chain unhooked and the motor unit is driven forward. When coupling is made, and the pivoted jaws are closed in the eye of the connecting bar, the spring on hand lever forces a lug between opposite ends of the jaws, securing the coupling till it is released by hand



This group represents three forms of standard practice for four-wheel trailers. (Upper) A loaded truck (designed on tractor lines) operates as tractor hauling two reversible trailers with dump bodies, having fixed axles and automobile steering linkage for each pair of wheels. (Oval) A clear case of the possibilities for surplus traction which the heavy loads on the truck's driving wheels affords. (Lower) Illustrates how the trailer system is applied to the domestic or industrial wants of farmers who own automobiles

The local roads need not be favorable if the goods handled are too bulky to make a full-weight load in the loading space of standard truck bodies. In the large majority of instances the economic issue is much clearer than it ever was between electric trucks and gasoline engine trucks. To decide it, one must know the facts—the facts of the business in question, of the motor trucks on hand or in the market, and of the trailer vehicles and methods.

Though it is generally said, or even admitted by trailer manufacturers, that trailers cannot be used very well for retail merchandise delivery, this implied restriction of the field seems too broad. Tricycle delivery carts operated on the semi-trailer principle have been employed successfully for many years, specially in Europe, antedating the heavy semi-trailers and escaping their name. And the side-car, which is also used for light delivery work, may be considered as a motor unit with a trailer at its side. The possibilities for light semi-trailers for this field of work seem to be wide open.

Adaptability to Requirements

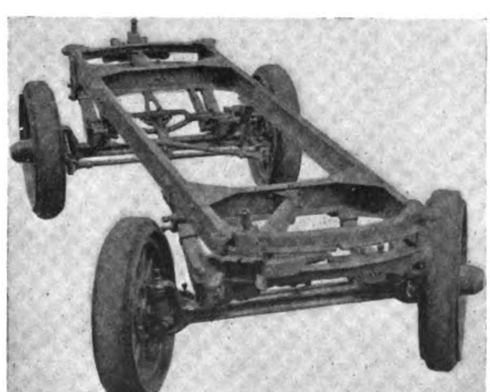
Perhaps the trailer system has been viewed too closely with reference to the improvement in load capacity which it offers in comparison with motor trucks alone. Trailers are based upon the fact, it is constantly said, that every motor truck, to be able to cope with emergencies, must be superpowered for its normal work, so that the idle surplus of motor and man power can and should be utilized for hauling additional loads whenever the working conditions are dependably normal, and particularly where road surfaces and grades are favorable. The same reasoning would argue for very large trucks with very small power, if other considerations were not active. But industrially and commercially only a limited number of motor types can be made and marketed, and the salable type is the superpowered truck having a large range of working capacity plus a margin for temporary or permanent deterioration.

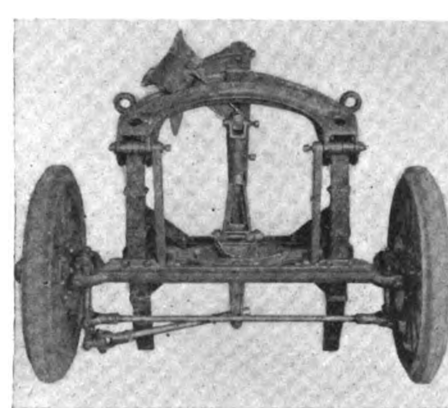
The trailer system does more than fill the gaps between motor trucks of different types and sizes; it adds a flexibility in operation which the largest assortment of specialized motor trucks could not supply in practice and provides a way for taking care of loads of abnormal lengths, bulk or weight which are incompatible with transportation in normal motor truck bodies.

Motor trucks have done so well that this broad opportunity for the trailer system could be slighted for a while, but it is now accentuated wherever loading time and waiting time make inroads in the truck's working hours, and in the driver's. There it appears plainly what the indivisibility of the motor truck unit means economically in contrast with the great flexibility in operating methods which trailers introduce and render practicable. What chance, to mention a parallel case, would electric trucks have had if batteries and battery cells had not been removable and interchangeable?

Three Main Characteristics

The trailer system is thus seen to be based on three principal characteristics. It is not based on the possibility of hauling a larger load by sailing closer to the

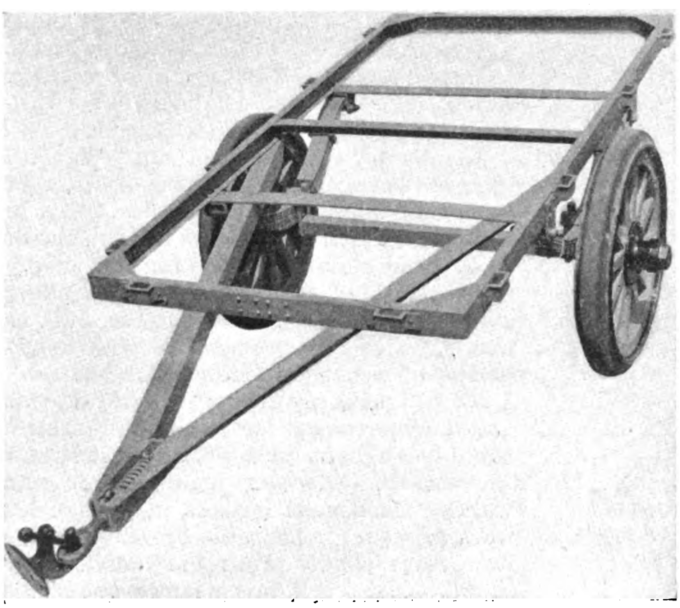




To the left—Another typical four-wheel trailer chassis. Outstanding features are the use of radius rods to safeguard the steering against being influenced by oscillations of the vehicle springs and a pivoted connection between drawhead and drawbar. This connection is utilized for backing but is ordinarily immobilized by a locking bolt. To the right—One end of chassis tipped to show details of steering gear from underneath. Drawhead is shown in pivoted connection with the locked drawbar

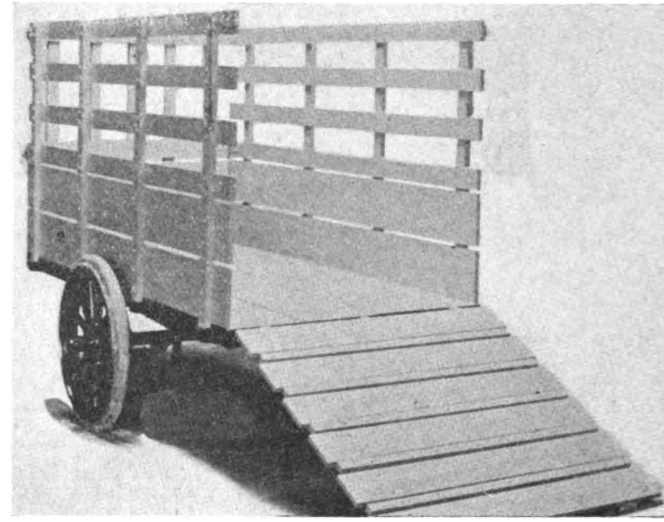
chance of a stall than a motor truck is expected to do. That would not be good business. But it is based on—

(1) Increased load capacity due to a better fit to the work on hand than normally may be expected of an unchangeable and uncompromising motor truck unit.
(2) Suitability for loads so awkward in shape, bulk or weight that the motor truck cannot handle them.
(3) Compound transportation unit, flexible in its application to work of varying demands and suited for keeping engine power and man power profitably employed during all the working hours.



Simple construction of typical two-wheel trailer with drawbar attached to pintle hook secured to the motor unit. The frame shown is adapted for receiving a stake body

Labor recognizes the last-mentioned point when it usually demands a somewhat higher wage where trailers are regularly employed. It wants a share in the advantages, and usually gets it. It gets the same in other cases without giving the value in work which is secured automatically by the trailer system properly organized.



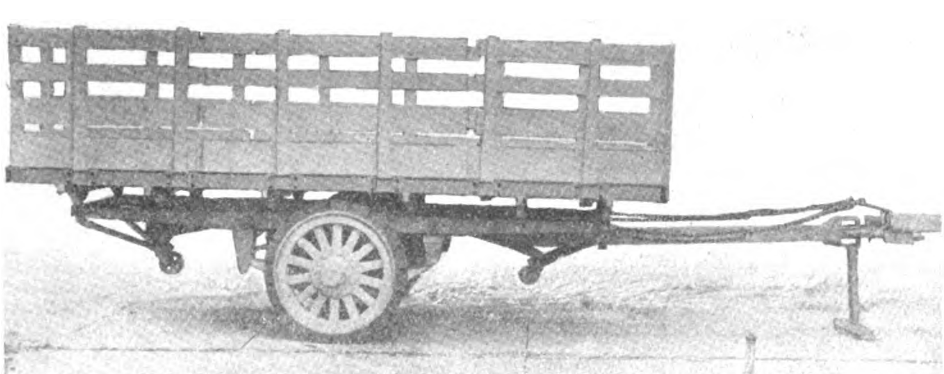
Light two-wheel trailer intended for transporting of one head of cattle and provided with hinged end gate than can be used as a ramp, as shown

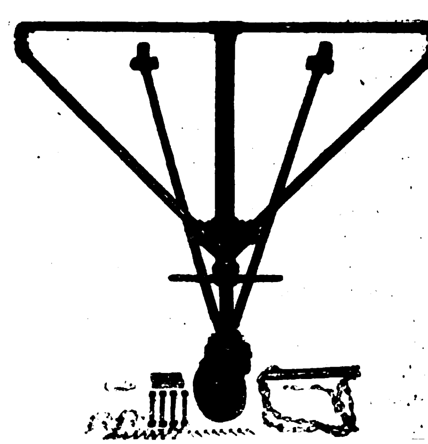
The semi-trailer type is often employed solely to gain the operative advantages of a "divisible unit," including that of the short turn, and this type has already reacted upon the motor truck industry with great force, causing short-wheelbase trucks or tractors to be manufactured specially for semi-trailer service. The tractor, the truck and the trailer are blended in variable proportions in this compound transportation unit.

Mechanical Construction

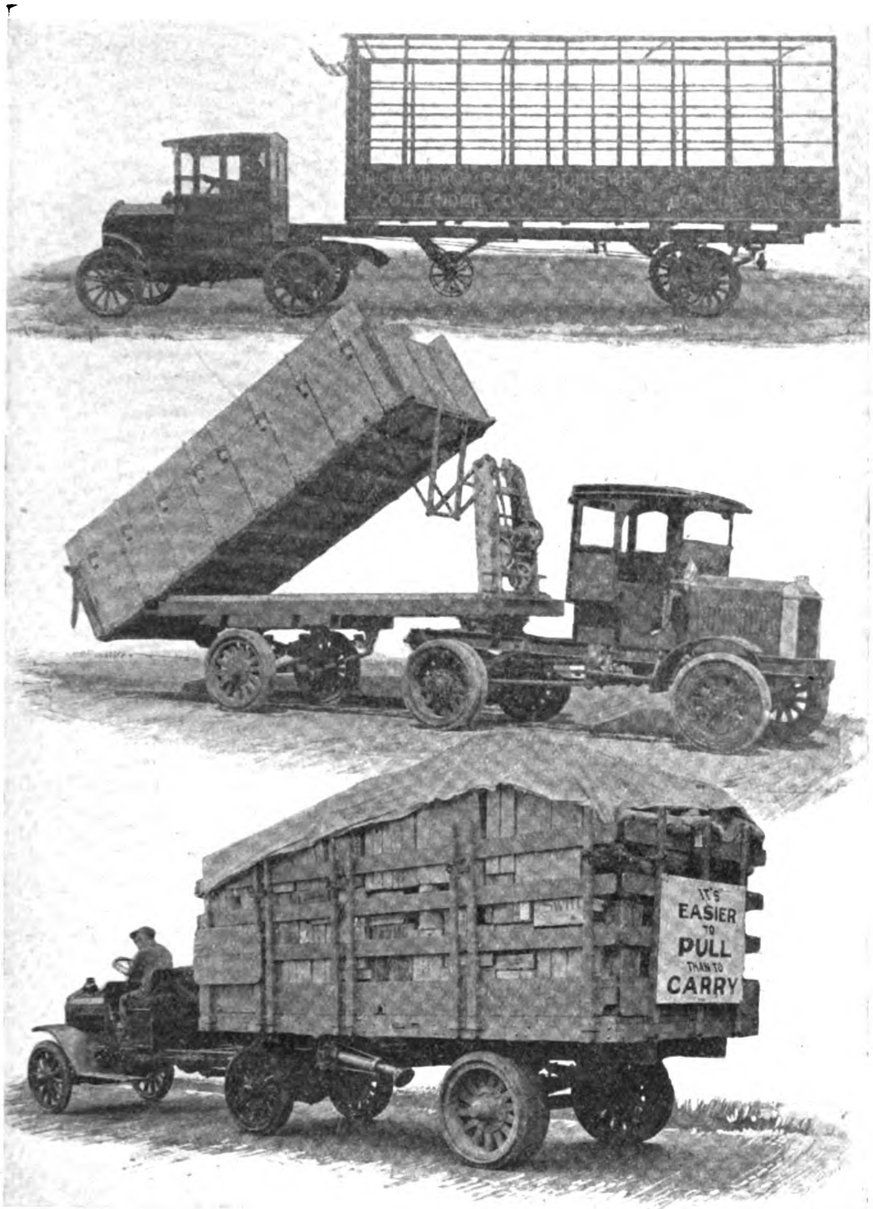
Much has been written on these fundamental matters and they are perhaps clear in principle to a majority of those interested, but when it comes to choosing a trailer outfit its mechanical construction detail and the relation of such detail to the work contemplated naturally enter for consideration.

The parts are not mechanically complicated, and generally accomplish what the maker intended, but there is some difference of opinion as to the necessity or importance of the functions. The intentions vary somewhat according to the views held, but more according to the type of the trailer outfit. The main points of interest in this respect are indicated in the accompanying illustrations and their captions. Some of the leading ideas





(To the left) Heavy two-wheel trailers known as "flats" are sometimes used with a truck as the motor unit. The connecting bar is adjustable in length and height and is hinged to a cross member of the trailer frame. The trailer load can be dumped automatically by releasing a lock on the drawbar and backing the trailer slightly, forcing the center of gravity backward beyond the vertical plane of the axle. Upon moving forward, the pull of the drawbar brings the body back into the horizontal position and locks it to the drawbar automatically. Folding screw jacks serve to uphold either end. (To the right) One of the folding screw jacks with caster foot. A similar jack is sometimes used for light semi-trailers



This group shows typical semi-trailers in use. (Upper) The fifth-wheel connection is here automatic and the required rocking movement in the relations of the trailer to the motor unit is effected by two rollers which also steer the two units into or out of hitch, running on rails with converging guide flanges. The foldable front support of the detached trailer takes the form of two substantial wheels. (Center) The use of dump bodies for semi- trailers is here exemplified. (Lower) The heavy structure, carrying the motto of the trailer industry, is provided with a telescoping folding jack, for supporting its front end, having a foot that rocks freely to perpendicular or slanting positions of the jack

in connection with this phase of the subject may be briefly mentioned separately, however.

If the trailer reduces the road speed, some of its advantages are lost, and it is therefore the aim to produce a construction which admits of as high speed as for a motor truck alone. In practice motor truck speed is perhaps actually reduced an average of 10 per cent to 15 per cent when the load is doubled, owing to the larger amount of work done and more frequent employment of the lower gears, but the speed consideration has led to very substantial construction of trailer chassis and to the adoption of interesting devices for securing accurate steering, approximate tracking, elimination of slamming in couplings, avoidance of shifting of loads and of all independent accelerations and decelerations of the trailer. Backing and maneuvering call for other mechanical provisions. The needed facilities for coupling, uncoupling, loading and unloading vary for the different types.

The ideal, mechanically, would be to have all trailer outfits perfect and foolproof on these points, but cost, weight and simplicity of construction are also involved, and the requirements vary greatly in importance as between outfits intended for 5 to 10 miles per hour with loads of 5 to 20 tons and other outfits meant for 15 miles per hour or more with loads which may be of great length or volume but of relatively small weight. The suitability of the mechanical equipment of trailers can, therefore, scarcely be judged on general principles but only with sharp reference to the line of business for which they are designed and the nature of the roads in the territory where they are to be operated.

The same may be said of choosing among the four types of outfits. In all cases there is a premium for applying to the limit the traffic manager's common sense and experience in his line of transportation work, while in the selection of motor trucks good business judgment is not enough but must be supplemented by scholarly insight in engineering and positive knowledge of the truck data which experience has established. The unaided business man must usually rely in large degree on commercial faith in buying motor trucks, but in buying trailers his own competence can easily be made good enough.

Summary of Mechanical Requirements

The requirements and functions which must be reflected in the mechanical equipment of trailers may be summarized as follows with special reference to each of the four types and to train formation:

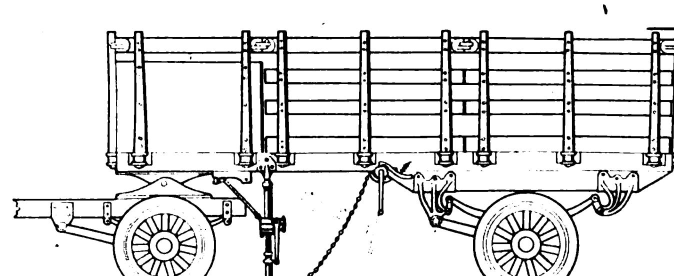
Four-wheel Trailers—Operation by one person, and he the driver of the motor unit.

Coupling and uncoupling handy, safe and reliable but not necessarily automatic.

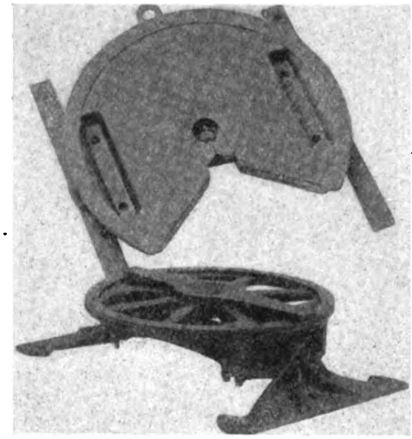
Double-cushioned drawbar action.

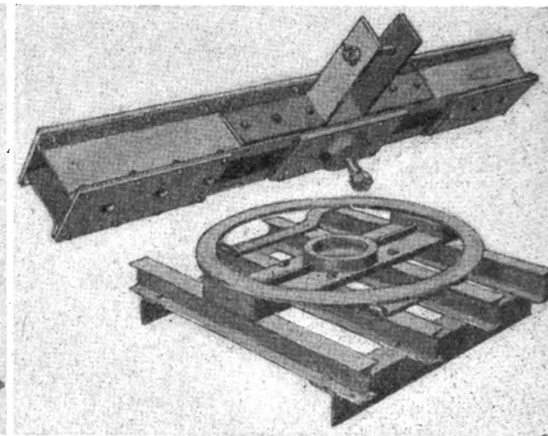
Automatic steering in tow.

Tracking with driving wheels of



Twin screw jacks hinged to trailer frame and arranged to be folded away by chain and winch. Both jacks are raised or lowered in unison by a crank from either side, but each may be adjusted independently





(Upper left) To make the fifth-wheel device couple automatically, a type has been developed in which the lower disk has a gate with converging edges and spring actuated locking jaws which close around the kingbolt in an annular groove when motor and trailer units are brought together. (Lower left) In semi-trailer equipment the fifth-wheel coupling is paramount, as it must transmit the traction pull, must cushion starting and stopping actions, steer the trailer and permit the latter varying relations to the motor unit. The top disk is bolted to the underside of the trailer body or frame and carries the kingbolt which couples the upper and lower disks, so as to maintain continuous contact between them and avoid wobbling. The lower disk is pivotally mounted by means of a transverse bar in brackets secured to the motor unit, so as to admit of forward and backward rocking, and the bar is held between drawbar springs allowing as much other movement as is necessary. (To the right) Details of a fifth-wheel device intended for a heavy pole-trailer. Rocking movement is effected by using a single transverse bolt for connection of the bolster with the adjustable trailer pole. Load chocks and adjustment chains are used, but are not shown

motor unit, approximate or as close as demanded by law.
Backing and maneuvering.
Braking, if high speeds or hilly roads are factors.
Reversibility, if required.

Two-wheel Trailers—Simplicity is the keynote for this type, which is usually intended for light loads balanced over the axle.
When intended for heavier work, drawbar and couplings should be equal to those required for four-wheeled trailers and should tend to prevent teetering.
Supports for either end when the vehicle is unhitched, to facilitate loading.

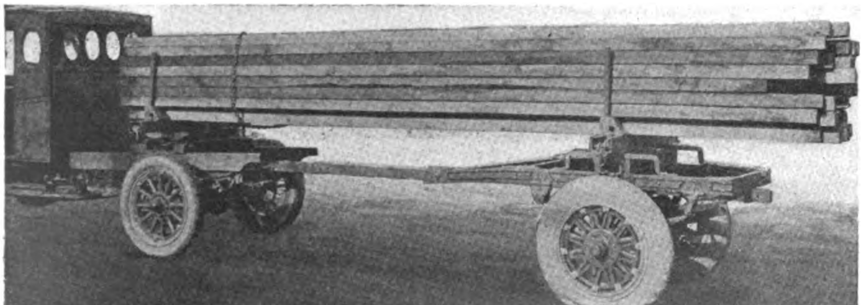
Semi-trailers—Operation by one person, and he the driver of the motor unit.
Equivalent of double-cushion drawbar action.
Adequate support for front end when unhitched, adjustable in height.
Simplicity of coupling and uncoupling, preferably automatic.

Pole-dollies—These share the nature of semi-trailers in some degree, as a portion of the load is always supported on the motor unit.
Adjustability to length of load, by extension reach.
Provision against shifting and twisting of load.
Equivalent of double-cushioned drawbar action, for heavy loads.

Train Formation—Four-wheeled trailers intended for use in train formation must have a steering and tracking system that will operate properly for this condition of service.
Close tracking, essential for short turns.
Reversibility, with drawhead for coupling at either end.
Trains of semi-trailers are not known to be in use.

Steering and Tracking Automatic.

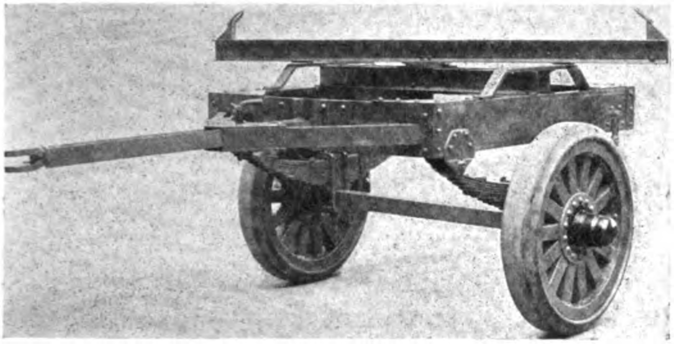
With reference to automatic steering and tracking, it may be recalled that rear wheels of wagons and motor vehicles do not track accurately with the steering wheels, but each wheel follows its own curve. To track accurately, it is evident that the follower-wheel should not begin to turn until it arrives at the spot where its leading wheel began turning, but the follower-wheel, when left free, begins turning at the same moment (instead of at the same spot) as the leading wheel. Close tracking must, therefore, be forced by positive mechanical action and consumes a little more power than free turning. It causes more tire strain and wear. It seems also probable that an automatic steering and tracking method, by causing the wheels to depart from the lines of smallest resistance in a more or less irregular manner—if the design is imperfect—may become responsible for a tendency to "snaking" at the higher speeds, considering that most road tracks are more or less tortuous while all positive mechanism for guiding the wheels, including the automobile or Ackerman system, has so far been only approximately correct, and is liable to be less correct when close tracking is aimed for.



Pole-trailer at work in lumber business. Shows similarity to semi-trailer type, but towing connection between the units is by adjustable pole, and load rests on swiveled bolsters and is closely held between laterally adjustable chocks and stakes forming parts of the bolsters

The trailer industry, as the illustrations show, employs both the Ackerman and the fifth-wheel methods, opinion being divided with regard to their comparative merits. Tracking may be approximated sufficiently well by either, depending much on details in design and workmanship. The issue between the two methods may be decided by considerations of load space and body shape. Side dump bodies, for example, find a large available space with low drop frames and rod-steering than two fifth wheels would allow.

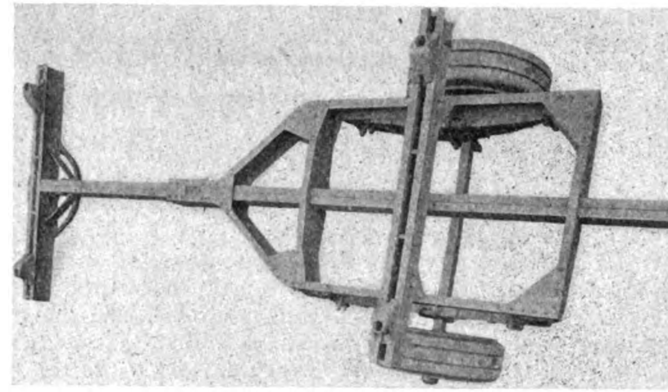
As to the degree of accuracy in tracking which is provided, we are practically stopping now at the idea that front wheels of each unit are made to track quite closely with rear wheels of the preceding



Pole-trailer with long pole adjustable, with a locking device in the trailer frame, to different distances from the motor unit, to which it is coupled by eye and pintle hook. Front end of load rests on bolster swiveled to platform of motor unit, similar to swivel bolster on trailer

unit, speaking of four-wheel trailers, but rear wheels are left free—a sensible compromise favoring simple construction and applicable in train formation.

Questions relating to the steering system are subject to debate, of course, and may be more fully elucidated with diagrams, but they are overshadowed in practical importance by questions of progress in couplings and supports. These apply particularly to semi-trailers, but also to two-wheel trailers and dollies. It is reserved for inventive ingenuity to make them more fully automatic while losing none of their present dependability.



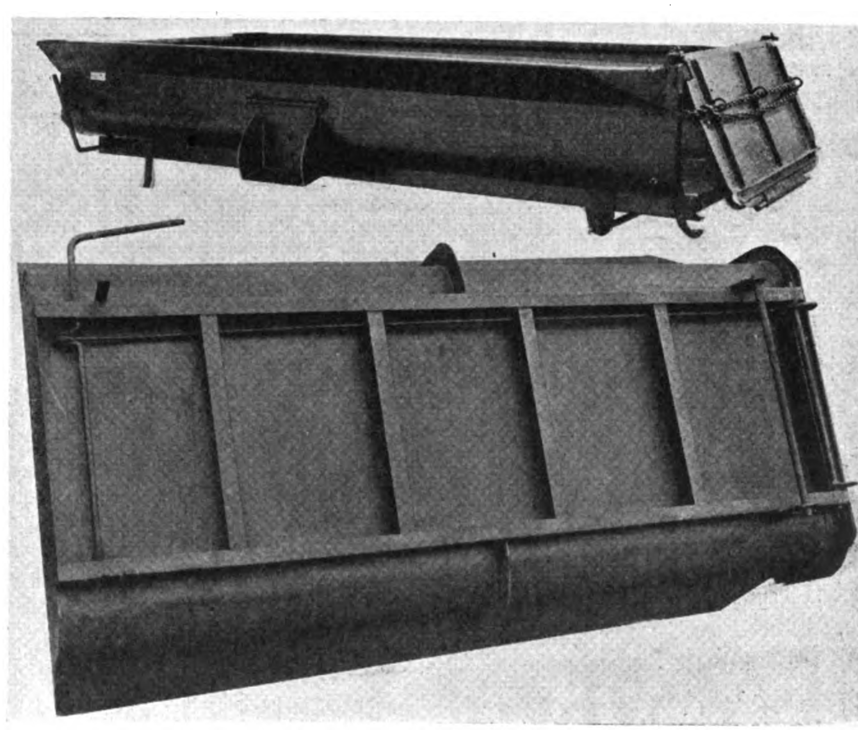
When intended for heavy loads the adjustable pole of the pole trailer is sometimes provided with the upper portion of a fifth-wheel coupling and a front bolster integral therewith, and neither front nor rear bolster is then swiveled. The picture shows adjustable load chock arranged for receiving round stakes

New All-Steel Truck Body

METAL construction, strangely enough, has not made as much progress to date in connection with truck bodies as with passenger bodies, although the service conditions in truck work are much more severe. Herewith are shown two photographs of an all-metal truck body made in Kansas City, in the production of which the electric welding process plays an important part.

The body is practically one piece, for the individual parts are welded together electrically. The longitudinal sills and cross sills are formed into a girder-like structure and provide a rigid bed to which the body itself is welded. This construction produces a body with a smooth interior, which is an advantage when hauling clay and similar materials, as there is then very little tendency for the load to adhere to the body when the latter is tilted.

Another feature is the double acting tail-gate which can be opened either from the bottom or the top. When opened from the top the two cotter pins are removed, as shown in one of the photographs, and the opening may then be regulated by the adjusting chain.



Two views showing the construction of the all-steel truck body

AN average of 120 pounds of aluminum is used in the manufacture of all automobiles—Fords excluded—according to a brief filed by the National Automobile Chamber of Commerce with the Ways and Means Committee of the House of Representatives. This figure was obtained from the Aluminum Company of America and it refers to the allotment of the crude aluminum set apart for the automotive industry by this company. In some cars the weight of aluminum used is as high as 250 pounds. The automotive use of aluminum is estimated at 120,000,000 pounds, 60 per cent of the production.

The brief was filed as supporting the request that the present duty on aluminum of two cents a pound should not be increased. One of the present obstacles to the use of aluminum in our industry is the price and if the tariff is removed, the demand for the metal would increase.

A British Traction Dynamometer

Instrument designed by National Physical Laboratory intended primarily for use in measuring drawbar pull of tractors. Hydrostatic pressure on plunger is registered on Bourdon gage and recorded together with time on paper arranged to travel at a speed proportional to that of the tractor.

THE National Physical Laboratory designed a special traction dynamometer which can be inserted between the tractor and plow without interfering with the control of the plow by the tractor operator for use at the farm tractor trials held at Lincoln, England, during the fall of 1920. To make this possible the recording instrument is separated from the dynamometer proper and placed on a light wheeled carriage which is towed alongside the tractor under test. The following description is abstracted from an article which appeared in *Engineering*.

The coupling between the tractor and plow consists of a cylinder and plunger, the former being attached to the draw-bar of the tractor and the latter, through links, to the plow. The pull on the coupling sets up a pressure in the oil confined in the cylinder, and this pressure is transmitted to a recording pressure gage by a flexible hydraulic tube. The best flexible tube that could be obtained would safely withstand an internal pressure of only one ton per square inch without reduction of flexibility, and as the dynamometer was required for pulls up to 3 tons, a diameter of plunger of approximately 2 in. was necessary.

The cylinder was made of steel and the plunger of bronze, the clearance between the two was made 0.001 in. and the plunger was provided with a very thin packing ring of oiled leather. In order to avoid the use of a gland the drawbar pull was converted to a thrust on a plunger by means of the links L, L, and the pins P_1, P_2. The thrust on the plunger is transmitted through the second plunger E, which is suitably guided in a continuation of the cylinder, and the connection between the two plungers is a loose one in order to allow the larger plunger to float freely in its cylinder. The pin P_1 passes through the slots in the guide-piece.

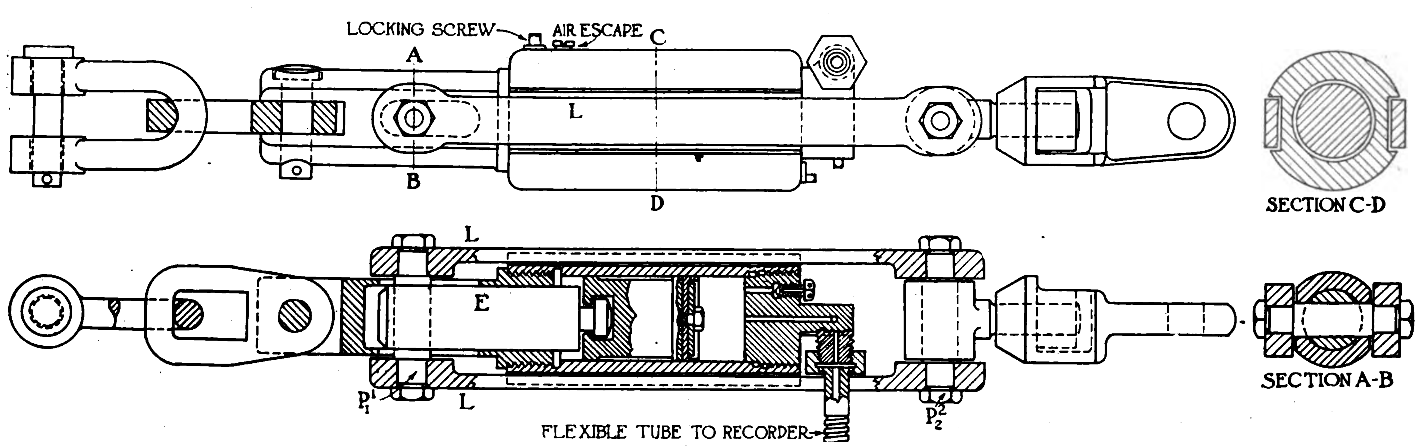
The connection to the tractor draw-bar was made in such a manner that the cylinder could rotate, and the opposite end of the dynamometer was provided with a swivel attachment for the plow. A rubber cover over the front portion served to exclude dust and grit from interior of cylinder.

The recording instrument consists of a standard Schaeffer & Budenberg pressure recorder modified for the present purpose by the addition of a second Bourdon tube, a clock, and the paper driving device. The recording paper is driven through gearing and a chain from one of the carriage wheels, and three speeds of the paper are provided for, namely, 1 in. of travel to 100 ft., 50 feet or 10 ft. motion of the carriage over the ground. The speed-change can be made while running if desired. As the recorder proper rests on the thick felt pads, the final drive is made by means of a leather vee belt, with tension adjustment. The hydraulic tube from the dynamometer is connected to a small valve-box, by which the pressure can be diverted to either of two Bourdon tubes.

The motion of the end of each Bourdon tube is magnified by a pen mechanism which is such that the travel of the pen is 4 in. for a maximum draw-bar pull of 4000 lb. using one of the tubes, and 3¾ in. for a maximum pull of 7000 lb. using the other tube. The pen mechanism can be transferred to either tube during a test if required.

A clock is provided for indicating time on the record paper. An electrical contact is made at equal pre-determined intervals of time which can be varied from 2 seconds to 6 seconds, and the time recording pen, which normally draws a straight line, is momentarily moved to one side when the contact takes place. A robust escapement from the clock is provided and in order that the number of time intervals indicated can be readily counted, every fourth contact is missed. Another similar pen is provided for recording revolutions of the tractor engine, or of the tractor driving wheels.

An oil pump taking oil from a small reservoir placed under the carriage, serves to prime the dynamometer and recorder. This pump is shut off when the apparatus is working. Measured distances on the chart between indications of equal time intervals are directly proportional to the speed, because the travel of the paper is proportional to the distance traveled. The average speed for an interval of 5 seconds can, therefore, be readily obtained, and the curve of speed plotted on the chart.



Traction dynamometer for measuring drawbar pull of tractors

A Budget Control System Which Is Producing Results

Manufacturers are taking special interest in the selling methods of dealers and distributers. This article gives valuable information which might be suggested to any distributer. The system deals with a branch-organized concern, but can be modified to suit other conditions.

By Norman G. Shidle

THE efficiency of budget control of finances has never been seriously disputed, but along with other recognized theories for good business administration such control is not always practiced. The present industrial situation emphasizes anew the necessity for business efficiency and demands in no uncertain tones a more economical and efficient expenditure of whatever funds are at hand.

Manufacturers are taking particular interest in the merchandising methods of their distributors and dealers, and are aiding in every way the intensive sales efforts which are being put forth. Probably no aid of greater value could be rendered than by the suggestion of a means of budget control which would eliminate waste and require a minimum effort for operation. Such a system has been developed at the Packard-Chicago distributors, and has been in successful operation for over a year.

The chief functions of this system of budget control, which is supplementary to the regular accounting system, may be enumerated as follows:

1. To enable the management to know at any time the exact status of the business.
2. To enable the management to pick out weak spots in the organization immediately and to bolster them up before any considerable damage has been done.
3. To place accurately and definitely responsibility for success or failure in a particular case.
4. To enable both distributer and branch manager to know which departments are making money and which departments are not making money. In other words, one department which is inefficiently operated cannot hide its deficiencies under cover of a total profit for the business.

The general purpose of the system may best be described by quoting from a talk made by C. G. Embleton, general manager of Packard-Chicago, when the budget plan was first presented to the branches. He said, in part:

"A budget system can be favorably compared to the governor on a truck. A truck without a governor is in a position to run wild at any time, and before long runs itself to destruction. Without some sort of a budget system, a business can also run wild up to the point of destruction, just as the truck can.

"A budget system is not a theory—it is a practical and necessary part of a business. Without such a system, the management is not in a position to purchase intelligently, whether it be the purchase of material or man-power. Without the budget you are not in a position to definitely know what to purchase and when, or how much money to spend at certain points.

"A budget plan, such as we have worked up, certainly will place the management in a position to know our business and how we stand at all times, and this also applies to every department head in our organization to whom will be handed that portion of the plan covering his particular department.

"Often we feel quite confident that a certain department is getting along in good shape, basing this opinion on their sales record and apparent efficient handling of their business, yet this analysis that we have taken brings to my attention a department that is not in healthy condition at all, and yet, prior to this analysis, I was of the opinion that this particular department was being handled in a very satisfactory manner.

"This plan will enable us to immediately draw our attention to the department that is weak. This being brought to our attention permits us to concentrate on this particular department and find out just what brings about the weakness as shown. It may be that the department is under-organized. It may be possible that there is too much help—too many of the wrong sort and not enough of the proper kind. It may be that the department will call for an extra advertising effort. At any rate, this plan will point out weakness, if any, which will permit us to take the necessary steps to strengthen."

The system devised is simple both in principle and application, but calls for a very careful and detailed study if its operation is to be thoroughly clear. To understand the working of the system, a general knowledge of the form of organization used by this firm is necessary. This does not mean that the system is applicable only to firms with a similar form of organization; on the contrary, it is adaptable to almost any of the usual forms of business organization. The purpose of presenting the chart of this particular concern is simply to facilitate a detailed explanation of the system.

The chart shown in Fig. 1 indicates the form of the Packard-Chicago organization. It will be noted that under the general manager there are four departmental managers, beside the advertising and financial managers who need not figure in this description. The service manager handles both parts and repairs. The budget administration is divided into these parts:

1. Carriages.
2. Trucks.
3. Accessories.
4. Parts.
5. Repairs.

In addition, however, the various branches function directly in connection with the general manager as well as indirectly through the various department heads. Each

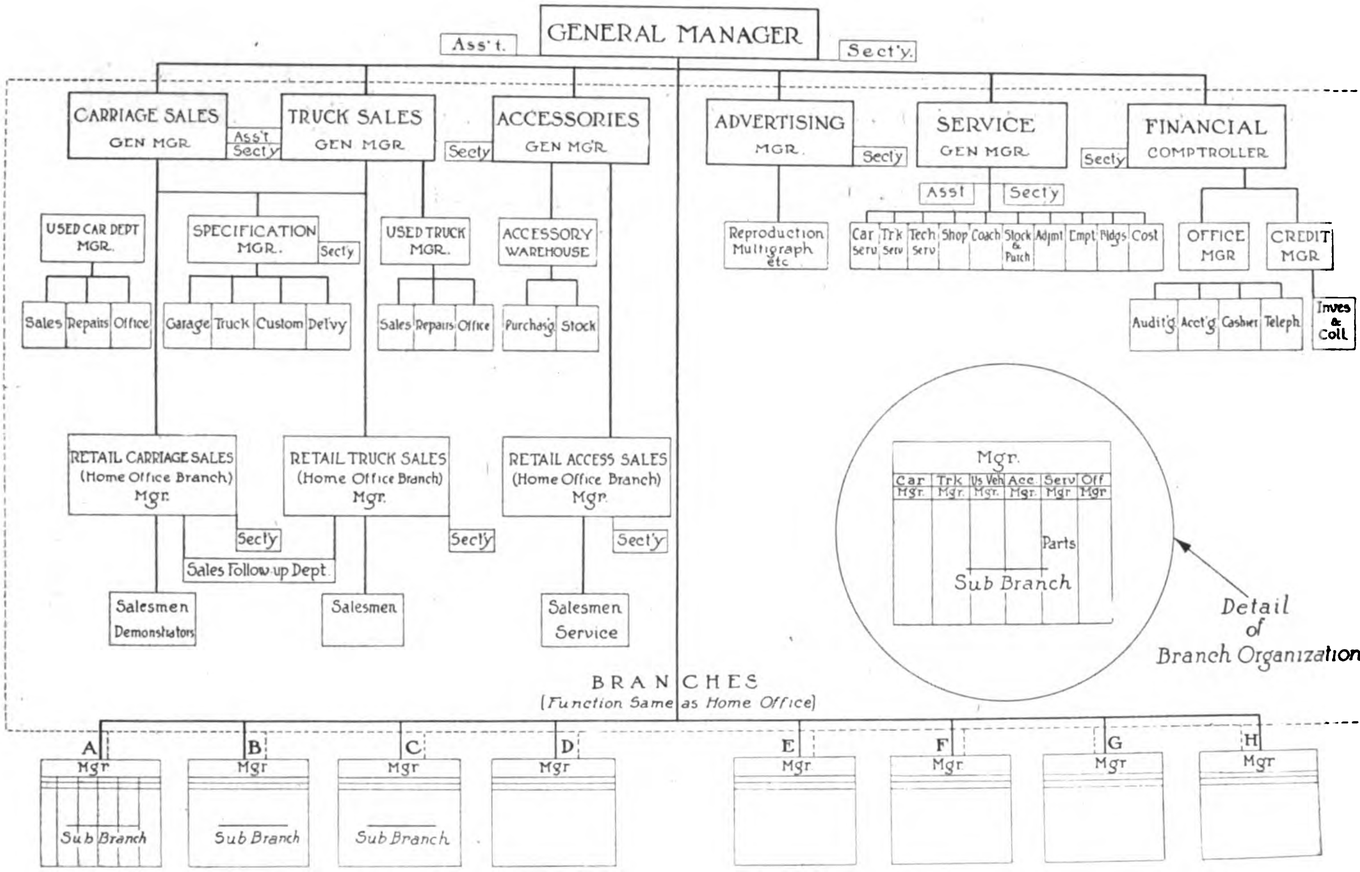


Fig. 1—Packard-Chicago organization chart

branch in turn has its operations divided into the five parts mentioned above, the branch organizations individually following the general lines of the main office organization. In the case of the smaller branches, of course, that organization is not carried out to as many refinements or with so large a staff, but in all cases the five departments—carriages, trucks, accessories, parts and repairs—are separately accounted for.

It may be well for the time being to forget the department managers, and consider simply the direct relationship between the general manager and the branch manager, for it is through this channel that the chief part of the system functions. The part played by the main office department heads can be fitted in later.

The first step is the determination of a quota for the year for the entire organization; that is, the number of vehicles which must be sold. The fiscal year extends from Sept. 1 to Aug. 31. The budget system is laid down to apply on the fiscal year and consequently the quota is determined by two operations:

1. Taking an inventory at time of beginning budget system.
2. Adding to that the shipment from the factory scheduled for next eleven months (assuming that system was installed at beginning of a fiscal year).

Since deliveries only, and not sales contracts, effect profits, shipments made during the month of August are not considered in the budget for the particular year, since the shipments made during that month will not be deliveries until the following year. This inventory of stock on hand and shipments to be received give the total of carriages which are to be sold. A similar form is used for trucks, accessories, parts and repairs, but the carriage forms will be used here alone to simplify the discussion.

The figure so determined is listed at the top of the form illustrated in Fig. 2. To make plain the operation, hypothetical figures may be inserted in the form. In this case, the quota for the entire carriage organization may be assumed to be, for instance, 800. Referring still to Fig. 2, the next figure to be filled in is the "average sales price," which may be assumed to be $5,000. This can be readily determined, of course, by dividing the total sales

Fig. 3

price of the allotment by the number of vehicles comprising the allotment. Next the gross profit per carriage is inserted; this is simply the difference between the buying and the selling price of the vehicle, and is in this case assumed to be $1,000.

The net profit desired is 8 per cent of the gross sales. Next are inserted the figures for gross sales and gross profit, both of which are readily calculated on the basis of figures already given. Since a profit of 8 per cent on gross sales is desired the net profit will be in this instance $320,000.

Subtracting this desired net profit from the gross profit of $800,000, the allowable expense figure of $480,000 is found. That is, $480,000 can be spent by the entire carriage organization in selling the quota of 800 and still make the desired profit of 8 per cent.

The data so far presented may in a sense seem to be "primer" material, but its chief utility is in its very simplicity. That is, the reasoning is simple enough, but the advantage lies in the clear, concise picture which is presented of the information as shown in Fig. 2.

Next the average monthly deliveries are filled in by percentages. By taking as an approximate basis the monthly averages for the three previous years, the percentage of the entire new quota which should be delivered each month is approximately determined. By means of this budget, a check on the selling progress of the entire carriage organization is available month by month. A certain percentage of the entire quota must be sold each month, and any "falling down" can be immediately checked.

A certain proportion of the entire quota is then assigned to each of the various branches. The individual quota of a branch is determined by records of previous years, together with an analysis of financial statistics for the particular region. In connection with estimating the sales possibilities of a particular territory, the financial statistics have been found to be a far better unit of measure than population figures; especially is this true as regards possible carriage sales.

On the bottom of this form, then, is listed by branches the number of vehicles to be sold by each branch during the entire year, the percentage of the total assigned to each branch, the gross sales in dollars expected of each branch, the gross profit desired, and the expense budget, that is the amount of money which may be expended by each branch in selling its assigned quota.

Thus, on this one sheet, is presented at beginning of the year in brief and clear form these things:

1. Quota for entire carriage organization, and total expenditures allowable for selling that quota.
2. Percentage of quota which must be sold each month by entire carriage organization.
3. Quota for each branch, and expenditure allowed to be expended by each branch to sell that quota.

This form presents in a broad way the task of the carriage organization, the scope of its work, and the limit of expenditure. This information is made available for the chief executive at a glance.

Centralized Cost Accounting

It must be noted at this point that the accounting for all the branches is handled through a central accounting department at the main office. That is, retail representatives of this organization who correspond to the ordinary dealers as regards sales functions, are really branch managers. Their bills are paid through the main office, and the costs of the various divisions of each of the branches are recorded and compiled at that central accounting office.

About the middle of every month, a balance sheet report for the previous month, together with a detail record of the expenses for his branch, is sent to every branch manager by the accounting department. These expenses are subdivided under the following classifications:

Miscellaneous Supplies.
Shop Tools.
Repairs to Machinery and Tools.
Repairs to Buildings, Fixtures and Equipment.
Power, Light, Heat and Water.
Errors and Allowances.
Miscellaneous Expense.
Rent.
Stationery and Office Supplies.
Telephone.
Telegraph.

An examination of the figures included in these reports enables the branch manager to fill out each month the columns marked "Deliveries and Actual" on his copy of the form shown in Fig. 3, original of which is in the general manager's office.

Fig. 3 shows the form upon which a branch manager reports each month to the general manager the progress of his carriage sales. He fills out a similar form for trucks, accessories, parts and repairs.

An examination of Fig. 3 will show that approximately one-half of the columns are filled out at the beginning of the year; that is, the figures which go into them comprise the budget limits for the particular branch. The first column, "Sales," is used simply for general information and does not enter into the budget system, since, as previously explained, only deliveries count. The "quota" columns under the general head "Vehicles" and "Per Cent of Quota" are filled out at the beginning of the year on the basis of the figures compiled and recorded on the form shown in Fig. 2. The same is true of the columns marked "budget" under "Gross Sales," "Gross Profits," "Expense," "Net Profit," and "Per Cent to Sales" records the percentage relationship of the net profit to sales for the month.

The other columns, then, are to be filled in by the branch manager every month, after he has received his cost figures from the accounting department. To make the operation clear, we may again insert hypothetical figures, taking the month of September as an example.

Referring back to Fig. 2, it will be seen that 6 per cent of the entire quota should be sold during September and that the "A" branch was assigned an actual quota of 100 carriages for the year.

Then 6 per cent of that 100 is 6 carriages, which comprise the quota for September. In the same way, using the basis established on Fig. 2, the gross sales budget for carriages for September is $30,000 and the gross profit budget $6,000. The gross expense budget is simply prorated equally for each month of the year, because it was found that an excessive amount of accounting procedure would be necessary if an attempt were made to pro-rate the expense budget in accordance with the varying expense of each month. Thus the expense budget for September would be merely one-twelfth of the yearly budget or $5,000. The next profit budget total for the year is figured at 8 per cent of gross sales, but because of expense distribution being equal, the monthly budget profit per cent varies, and we see that this month only calls for 1000, or 3.33 per cent for the carriage department of this branch. Though expense is equal in its distribution, the net profit per cent called for in later months will of course be higher, due to deliveries being seasonable, and the total budget for the year as mentioned above will be 8 per cent.

The balance sheet and expense accounting reports, from the main office, it is evident, are necessary for filling out the "Actual Gross Profit," "Actual Expense," and "Actual Net Profit" columns. This entire budget system is supplementary to a thorough and efficient accounting system, the

Fig. 5

purpose of the budget system being to limit expenditures, map out necessary achievement in advance, and present to both general manager and branch managers at any given time a clear and brief picture of the exact status of the business and all of its component parts.

Each branch manager, then, fills out each month a copy of Fig. 3 or each of the five departments of his branch, and studies them, while waiting comments from the general manager. Before noting the further use of the assembled branch office reports made by the general manager, it is well to note the use of the reports to the branch manager.

The form described enables the branch manager to determine immediately whether or not his carriage department is operating as effectively as it should. He knows each month whether each of his departments is yielding the fair profit desired. It is not enough that his branch is making money, each department must be operating profitably. By these five similar forms, the progress of each department is noted separately, and he is informed immediately by this record if any unit is not coming up to the standards set.

He can compare, at a glance, the actual expense with the budget of allowed expenditures. If that actual expense is higher than it should be, he can immediately refer to his detailed cost list and determine what expenses have been too heavy, and whether or not the increased expenditure was justified.

In addition to these five separate similar forms of each department, the branch manager is given each month the form shown in Fig. 4. This form comprises the same data as Fig. 3, except that the presentation is made in a different manner and brings out different points. Fig. 4 shows the comparative status of each of the various departments for the month, and below, the comparative status of the departments to date for the year. The branch manager can see, at a glance again, what departments are falling down, what departments are operating successfully. A duplicate copy of Fig. 4 is handed the general manager every month, together with an analysis, by the general manager's assistant.

From these reports data is compiled for the general manager which place before him a detailed, yet brief and concise, picture of:

1. The entire business.
2. The status of a particular branch.
3. The status of the various departments of a particular branch.
4. The status of the various departments of all branches combined.

When the form shown in Fig. 3 comes to the general manager, a summary of them is compiled and presented to the executive on an exactly similar form. Thus the executive has on Fig. 3 the same information for the entire organization that the branch manager has for his own branch. In like manner, the general manager has prepared a form similar to Fig. 4, which presents to him the facts in this classification for the entire organization. These forms differ only in that one is headed "A Branch," and the other "Entire Organization."

Thus Fig. 3 gives the general manager the month by month progress of one department of all the branches combined, a copy of which is given the division manager, thus effecting a united tie-up of sales effort and co-operative direction along lines of good business.

Fig. 4 gives him the status of each of the various departments of all branches combined, both for the preceding month, and to date for the year.

The general manager is enabled to compare at a glance the status of the various branches by reference to the form shown in Fig. 5. This form is compiled from the same data as was used in connection with Fig. 3, but is differently arranged in order to present a different phase of the business status. It shows the relation of the business of each branch to the budget for the preceding month; along with the same information for each branch to date for the year.

The forms shown in Figs. 6, 7 and 8 are almost self-

explanatory. These are prepared at quarterly intervals and are presented to the general manager as additional simplified data showing the status of certain phases of the business.

The form in Fig. 6 presents a comparison of gross profit, expense, and net profit for each department of each individual branch. The form in Fig. 7 is a comparison of gross profit, expense, and net profit average per vehicle by branches.

Fig. 8 shows a form on which the business of the various departments of the individual branches is compared on a percentage basis. The data on this form enables the general manager quickly to determine in a general way by the fairest yardstick which branches are doing exceptionally well and which ones are not coming up to the set standards.

It will be noted that the forms shown in Figs. 2, 3 and 4 are those which appertain directly to the operation of the budget system. That is, it is through these forms, and the other forms used, which are similar to them, that the actual operation of the business is compared with the standards set by the budget.

The other forms chiefly comprise data compiled from the information contained in the forms of Figs. 2, 3 and 4, but so arranged as to present clearly and briefly to the chief executive the exact status of any particular phase of any branch or the entire business at any given time. The forms shown in Figs. 5, 6 and 7 are little more than examples of an idea which is capable in innumerable variations and adaptations. That is, these same figures might be re-arranged and re-grouped in many other ways in order to present at sight certain other angles of the business. As a matter of fact, several other variations are used in the work of this organization.

If the budget control system consists in nothing more than the filling out of these forms, it would be comparatively barren of results and scarcely to be counted as profitable. The usefulness of the summarized information which can be placed before the chief executive in brief form is so obvious as to need no discussion. In no way other than the budget can the final net profit objective for the year be charted out and be made available by the easy stages of monthly comparisons.

The forms sent by the general manager to the branch managers, however, call for definite action. When these forms are first received by the general manager, he immediately dictates a short note to the branch manager upon any phases of that manager's report which seem to require it. Thus the attention of the branch manager is called to any deficiencies in his organization, and he is required to determine the "why and wherefore." Having done this he must reply to the comment of the general manager, explaining the reason for any trouble which has been brought to his attention, or noting the unusual circumstances which made the difficulty inevitable.

In this way every detail which goes wrong in any of the branch organizations is immediately apparent, and is immediately attended to and corrected. Such efficient action is obviously impossible without a budget system of some kind similar to the one described here. It is possible to know that a department is running behind only when a normal standard has been determined beforehand.

Fig. 7

It is necessary each year to make out Fig. 2 again, thus beginning every new year as though the system were starting for the first time insofar as the determination of the budget is concerned. This makes the budget for each year conform with current conditions and changes in the industry so that it always presents a fair standard by which to gage performance.

The system at Packard-Chicago is considered to have been highly successful in every way. As the operation continues further refinements and improvements are made, but the system as outlined here involves all the essential points necessary to insure an efficient and constant budget control of the various phases of the business. To George J. Saxon, assistant to the general manager, is due much of the credit for the effective working out and operating of this budget control system.

It has been impossible, of course, in an article of this length to explain every detail, but enough has been presented to show clearly how the system operates, and to indicate the workings of those parts not fully discussed here. The chief accomplishments of such a system of budget control are included in this list:

1. It simplifies for the chief executive the complex accounting reports and terms.
2. It gives the general manager and the branch managers simple, easily readable, concise pictures of the business.
3. It points out where control or greater effort are necessary and permits remediable measures at the time when they should do the most good.
4. It makes an accounting record a conversational picture instead of a set of cold figures difficult to interpret.

Cast Nichrome Carbonizing Containers

IN case hardening steel by the cyanide process, a great deal of difficulty is being encountered by reason of the short life of the containers which hold the molten cyanide. In the past these containers have been generally made of iron or steel, and these materials oxidize rapidly and holes burn through their walls, or cracks form in them. The loss of the container is not the most serious damage done in such a case, as the molten cyanide will leak through and destroy the fire brick lining of the furnace.

Recently, crucibles or containers of a nickel chromium alloy, known as nichrome, have been used for this purpose. Nichrome (which is made by the Driver-Harris Co.) has the valuable property that it resists corrosion at high temperatures. One of its earlier important applications was as resistance wire in electric circuits where the wire sometimes becomes exceedingly hot yet must not oxidize.

Cast nichrome can be machined readily with high speed tool steel, but owing to the toughness of the alloy the tools must be ground with special angles. The use of the alloy is practical at all temperatures up to 2000 deg. F. Not only does it not oxidize at these high temperatures, but it is also practically non-warping, retaining its shape up to the temperature limit mentioned. The alloy can also be forged when heated to the proper temperature, but it must be handled very carefully. It is malleable and ductile, but during the rolling and drawing operations, repeated annealings are necessary. It can be readily welded by experienced welders, by either the oxy-acetylene or the electric arc method. The operation calls for considerable skill, however, as welds of cast nichrome cannot be made in the same manner as a weld of cast iron or steel. Preheating is almost invariably necessary, and a thorough cleaning of the surfaces to be welded is important. The best results have been obtained by chipping, with an air or cold chisel, the surfaces of the parts to be welded, so that new metal is exposed. A flux is necessary for gas welding but not for arc welding.

Besides its great resistance to oxidization at high temperature, nichrome is resistant to the action of most acids and alkalies, hot or cold, and the castings are said to give satisfactory service in a great many applications in conjunction with the use of acids. The melting temperature of cast nichrome is 2660 deg. F., the softening temperature 2300-2200 deg. and the same working temperature 2000 deg. The specific gravity is 8.15. Its specific heat is 1.1 at 68 deg. F., and the weight 0.29 lb. per cu. in. It shows a Brinell hardness of 160-170 and a scleroscope hardness of 27-30. The coefficient of linear expansion is 0.0000091 per deg. F. between 32 and 212 deg. F.

Following are the physical properties at 70 deg. F.: Elastic limit, 40,000 lb. per sq. in.; ultimate tensile strength, 54,000 lb. per sq. in.; elongation, 1 per cent; reduction of area, 2½ per cent.

The physical properties at 1500 deg. F. are as follows: Elastic limit, 20,100 lb. per sq. in.; tensile strength, 24,500 lb. per sq. in.; elongation, 4 per cent; reduction of area, 4.3 per cent.

Experimental work done by the Driver-Harris Co. has led to the conclusion that the most efficient and economical cyanide furnace is one in which the cyanide pot is sealed into the furnace by means of a seal of chrome ore or magnesite. The seal is placed between the brick lining and the flange of the pot. In this type of furnace the waste gases of combustion are led into a separate flue, and there is, therefore, no connection between the combustion chamber and the hood which covers the cyanide pot. This method of construction effectually prevents the cyanide vapors from passing into the combustion chamber, thus prolonging the life of the nichrome cyanide pot.

Other advantages of the use of cast nichrome containers are a saving of cyanide, an increase in the life of the furnace lining and a more uniform temperature.

Cast nichrome containers are also used for lead hardening. Round, rectangular and bath tub shaped lead pots are made of cast nichrome in all sizes and weights, the largest being of 2000 lb. capacity.

For some years past cast nichrome has also been used for pyrometer protection tubes. Iron or steel tubes were formerly used for this purpose, but cast nichrome tubes are said to have proven much more durable. These tubes are supplied in either the plain, threaded or flanged forms, with either light or heavy walls.

The above information is taken from a book on Case Carbonizing published by the Driver-Harris Co.

THERE has been compiled by the Bureau of Standards for distribution, a table of equivalents of cubic feet in terms of cubic meters arranged in units from 1 to 1000 cubic feet; also cubic meters in terms of cubic feet, the arrangement being by tenths from 0.1 to 29 cubic meters.

What Dealers Think About Merchandizing New Models

There can be two reasons for a new model; one strictly a merchandizing reason, the other to keep the motor car up with the times. The latter point is for the engineers, and is not considered here. The dealers quoted in this article have decided opinions on the other point.

By Clyde Jennings

FOR what seems to be a very long time we had a market in which the factory capacity was the measure of car production. Now we are entering a period during which the car production will be measured by the selling capacity of the dealer.

This entire reversal of the situation makes for much more interesting circumstances. In the new circumstances there is not much of romance or thrill in the factory as a whole. It is only the production or labor man, who gets into the details which cannot be passed on to the public, who senses the thrill. There is too much that must be kept secret. In the recent past there was too much of "passing the buck" in the way of paying fancy freight rates and increased wages that were merely passed on to the public, through the kindly influence of the dealer. **Even the labor problem lost its savor when the men were merely bribed to work.**

During this period one very interesting observer remarked:

> **"We buy our automobiles from the man who insults us the least."**

Now it all is so different that it looks like a new world. The automobile selling situation, and in fact the entire industry, is like a landscape the morning after a big snow storm. Here and there is a spot where some dealer, who was happy in his factory connection, an optimist by nature and with something of the bulldog in him, just kept on selling. These dealers are the spots in this landscape where the snow has melted. Here and there is a larger spot where a factory, with a sales campaign unspoiled by days of hurry, has maintained production.

But in the main the landscape is unspoiled except by the memories which are covered. There is a fine opportunity for a new line of work. If this opportunity was mine I would do this thing as a starter:

> **Get very close to my dealers and hear what they think about my methods and what advice they have for the improvements of these methods.**
>
> **Listen to the advice of any man who can sell cars to the user. More than that, seek his advice, even ask for it and promise him immunity as a reward for his testimony.**
>
> **And the more sullen the dealer or salesman appeared to be, the more his advice would be sought. I would try to learn of every sore spot in his memory.**

Do the dealers have opinions?

Most certainly they do, and very frequently they are quite intelligent opinions. This may surprise some factory sales managers and advertising managers (more of the latter), but it is true and I know a good many successful sales managers who have the highest respect for dealer opinions. There have been some changes in selling and advertising staffs during the last few weeks that have been very interesting. Several men whose names and methods were recorded unfavorably in memory have sought new jobs.

It seems to be difficult for some men to learn that arrogance is not knowledge and that the show of arrogance does not often impress the other fellow.

But enough of this. The object of this article is to present to the manufacturers and their sales departments some opinions on a much discussed topic:

That of the changing of models.

Thirteen dealers have testified through a channel that was entirely friendly to them as to their best opinion on the merchandising side of the new model program. These opinions do not agree. That was to be expected. They do, however, indicate that a number of factories have treated their dealers fairly on this point. In fact, the factory record here is not nearly as bad as in other points on which these dealers testified. But the ideal is not arrived.

> **One interesting point is the outspoken opinion of several of these successful automobile sellers that the announcing of a new model is not a good merchandising point at all and that changes should be made entirely without the brass band accompaniment.**

Here is the question these dealers were asked to discuss:

> **When do you believe that models should be changed? Supposing you have on hand quite a number of cars and the model is suddenly changed, do you believe that the dealer should be given protection for those which he has been unable to move prior to entrance of new models?**

The first reply reads like the feudal system of government was in control of the automotive industry. Read it:

1—It is always bad policy to change models in midsummer. This makes the dealers stop buying and has a tendency to make the public stop buying, not knowing what is going to happen. This is especially bad when it comes immediately after having liberal shipments.

> **It is a well known fact that many manufacturers load up the dealers and distributers when about to change models and even though changes are not made, if the dealer does not take a certain number**

of cars, which would be impossible for him to sell, the factory will take the agency away from him leaving him with a lot of cars on hand.

This is also bad for the new dealer as well as the old inasmuch as the old dealer is often forced to sell at a low price in order to dispose of stock on hand.

I believe that models should be changed in any event about Jan. 1. Dealers should have an ample protection and ample notice of the change of models. Dealers should have at this particular time protection against decline in price where there is so much talk of depreciation of value.

—

The next two opinions are milder but point to the wrong:

2—Most of the standard car factories are not making any model changes and have not in the past two years. They have come to the conclusion that the series system is preferable. Make slight changes as they go along. I do not think that any reputable factory will change its model and leave the dealer hold the sack. They can never build up a real dealer organization with that policy.

Witness the Blank factory to-day. Their past sins are enough to keep the live one off of them. The factory that treats their dealers thus is composed of poor business men, and the dealer left in the lurch with old models on hand will gain if he ceases to do business with such concerns.

—

3—Model changes should be made Jan. 1, and first announcement at New York shows. Factories that wish to be square should protect their agents against change of models, unless plenty of advance notice is given that models will be changed. Too few factories give any consideration to distributer organizations but prefer to keep all distributers in the dark.

—

Now we will open the windows and let in some fresh air, for the next installment of dealer opinions indicates better thoughts about the factory. But they still are interesting:

4—The Blank people have always told us sixty days, at least, in advance when a model or a price was to be changed in normal times, giving us time to clear our boards and have our sub-dealers in the same shape.

During the present high cost of work, they have on all occasions, with the exception of one time, protected us as far as they could on all orders we had taken at the old price. This one occasion was entirely excusable and we distributers had to take our share of the loss.

I believe the manufacturer should notify the distributer and he in turn the dealers in advance of any change in model or price, and if the distributer or dealer has not been on his toes to move his product, he cannot consider that the manufacturer has not done all he could.

If the manufacturer does not notify the distributer, I should think that the distributer has a perfect right to use any means he could to get back at the manufacturer and to fight him to a standstill if necessary.

5—Dealers should be notified in ample time to unload. If over-stocked and they cannot unload, they should be given protection for cars they have been unable to move prior to entrance of new models. By notifying dealers sufficiently in advance of new models and not crowding or unloading on dealers, factories would receive the co-operation in disposing of all old models before new models come out.

—

6—I do not believe that any reputable factory would make any changes of model in mid-summer or at any time immediately following heavy shipments of previous models. Blank always makes its changes when the demand is at the very lowest point and so far it has protected the dealers to some extent on cars he had in stock. Another thing, it has always protected the dealer when there has been any reduction in price. Whether this will be done in the future, I cannot tell.

The factories would show very poor judgment in producing an entirely new model when the dealers were stocked heavily with the old ones.

—

The following replies are even more constructive than the last. These dealers have real opinions on this subject of such great mutual interest to the manufacturer and dealer. Read closely what follows.

7—Practically every factory has changed the very foolish method which prevailed heretofore of bringing out new models at regular intervals.

Practically all of them will pursue the plan of effecting improvements as they are perfected. In other words, as soon as a gear shift locking device is perfected by any factory, they will immediately be put into production without any statements as to changing models. Factories cannot expect distributers to operate on a large scale and carry a large stock, co-operate with them when production is large, unless they protect them in the event of a decline in price.

The fundamental principle of the business which has made it best for the manufacturer to set the resale price to my mind also makes it obligatory upon him to protect the distributer in the event of a decline.

—

8—I believe that the idea of changing models is soon to be a thing of the past. I believe the various manufacturers will arrive at a standard chassis and that such improvements or changes as they see fit to make will be made from time to time without advance notice or other schedule. In other words, as certain developments prove themselves, they will be incorporated into the standard product of the various manufacturers at any time of the year that the occasion may justify. This is my idea of the proper method of handling stock.

I know of several cases where dealers and distributers have bought very heavily to protect themselves against a price raise. It is poor merchandising to buy beyond one's reasonable requirements regardless of what the

Next Comes Contracts

In this series of articles it has been the endeavor to point out that the dealer in motor cars really has the basis for a lack of confidence with the manufacturer.

The strongest argument in the dealers' discontentment has not yet been presented in these pages. It is the contract which—since this series was started—has been the subject of some discussion and which will be discussed more broadly within the next few weeks than ever before.

price situation is. A distributer or dealer is not justified in carrying more than a thirty or sixty days' stock at a time.

It is better to let a customer wait a short time for a car than to be over-stocked at all times. A little more old-fashioned conservatism in the automobile business would be a good thing.

When the factories intend changing models, they should advise the dealers and distributers a sufficient time ahead to permit them to get in shape for such change. As I remember, this has been the policy of the majority of the more reputable manufacturers. This condition will, undoubtedly, take care of itself as other injustices must.

Where a dealer is handling a product from a factory that has the reputation of being tricky, he should refuse to load up to such an extent that he is liable to be caught with an over-supply of obsolete models.

—

There is a real constructive thought in opinion No. 8, which follows:

9—I believe new models should be announced about August or September. The distributer should know in ample time so that he can clean up his old stock. If a distributer has a large stock on hand, the factory should co-operate to move these models before the new model is announced.

This could be done by having each distributer send a detailed inventory to the factory about six weeks prior to the time the new model will be announced. The factory could check up and see which distributers are overstocked and distribute these models to other distributers who may be sold out and short of cars.

The factory should reimburse these distributers to the extent of carrying charges for the cars which they move for him to other points. By carrying charges, I mean interest, storage, handling, loading and insurance charges. That is, the distributer in New York who might receive automobiles from St. Louis whose regular charge from factory to New York is $80 per car, and if the charge from St. Louis to New York is $100, the factory should reimburse the distributer for his freight charges and refund the New York dealer $20.

—

10—Models should never be changed radically. To deliberately design a new car, engine, body and so forth is wrong in principle as it depreciates the owner's investment and harms the selling organization. No one objects to improvements and the factory should refine its product wherever it would mean service.

Radical changes are not necessary in the automobile from the standpoint of better operation.

As many or more people will buy another make through being offended at having their cars put out of date over night, than will buy the newer model to be abreast of the time.

If models are to be changed, there should be some protection. The last of the old models should be placed in the dealers' hands on about Nov. 1 and the first of the new models shipped after Jan. 1.

—

The three opinions that follow set forth a different view, but they are none the less interesting.

11—In this part of the country, we have a rainy season when the North is having winter. As a suggestion for time for changing models, I believe Jan. 1 of each year would be fair to all. When models are changed, the dealer certainly should be protected on the old style model, because if his customer does get an old style car, figuratively speaking, he never forgives the dealer who "put it over him."

12—The change of models in this territory and in the summer has not affected us very much as there has not been any dealer in this territory who within the last few years had enough cars in stock to affect him materially, but I believe that where a dealer has a lot of obsolete models in stock the factory should furnish him the parts to bring this model up to practically the same standard as the new model. The manufacturer knew he was making a change when he loaded up the dealer.

—

13—With the revamping of conditions we are now going through, I am expecting that only the sound, well managed distributer organization and dealers will remain and those kind of people are entitled, and I am sure, will get the proper kind of consideration from the factories in relation to the condition of the merchandise they have on hand in contemplation of a change of models or prices by the factory.

The factories we are doing business with, I feel confident, realize the necessity of being in proper accord with their dealers and distributer organization and always will have the welfare of their field organizations in mind when making such important moves as changes in models and prices.

The manufacturer who does not value the members of his firing line sufficiently well to take them into consideration to the above extent will not be able to do business with responsible field organizations. Wise manufacturers realize the necessity of protecting to a reasonable extent their distributer and dealer organizations.

—

It is our belief that these opinions are worthy of the consideration of the factory executive.

Study of Starting and Lighting Battery Characteristics

IN connection with the preparation of specifications for starting and lighting batteries requested by the Motor Transport Corps of the Army, the Bureau of Standards has made a brief study of the performance of these batteries in the operation of a few of the various types of automobiles; the experiments having been made on cars in ordinary running order. Performance curves showing the instantaneous demands upon the batteries when cranking the engines have been obtained by means of oscillograph records, these records showing characteristic differences typical of the design and condition of the various engines and starter systems. The initial values of current and voltage, which cannot be obtained by the use of ordinary indicating instruments, are shown at the time of closing the starter switch. After the starter has begun to turn, the current decreases rapidly, pulsating with the compression of the successive cylinders. The results which have been secured are to be regarded as suggestive rather than quantitative measurements of performance. They indicate the possibility of using this method for the study of problems relating to lubrication, ignition, compression, and distributer action. In addition, an exact method is secured for measuring the speed from one revolution to another. The characteristics of the charging current when the engine was running were also studied. Measurements have been made at different speeds, different throttle openings, and different temperatures.

Important Factors in Development of Foreign Trade

A visitor remarked the other day that we seemed to keep very close to fundamentals. Of course we do. Any study of the foreign field will reveal that American manufacturers neglect fundamentals. They can succeed only on proper fundamentals.

By George E. Quisenberry*

IT can be said that the coming months will test out the abilities of the American automotive manufacturers as foreign traders. The markets of the world have been ours for several years; whether we shall keep them remains to be seen.

But in the commercial fight that is certain to come we have several distinct advantages.

> **FIRST—The ability to manufacture more efficiently and on better production methods than any other country; SECOND—Our knowledge of advertising; THIRD—Our ability to provide adequate service.**

In each of these considerations the automotive manufacturers are world leaders. The problem now is to transfer them from the domestic to the foreign field and to use them in holding and extending our overseas trading.

The upward trend of exchange during the past few weeks has greatly heartened our exporters. With sterling leading the way, the currencies of almost every country have gained in value materially in the present movement and, with few exceptions, the buying power of foreign money is greater to-day than it was a few months ago.

This is one great advantage in favor of a reopening of foreign trading. But exchange, unfortunately, is something that the manufacturers themselves cannot control and cannot, by their own efforts, so effect that it will redound to their advantage. What they can control and what should be before them now, more strongly than at any time since the automotive industries first reached out after overseas business, is their sales and service policies. Here are the factors under which the individual exporter and manufacturer must stand or fall.

This article proposes to take up some of these things. Among them are:

> **1—Subjects as sales and service literature, 2—Campaigns for highway improvement, 3—Participation in motor shows and agricultural demonstrations, and 4—Above all, sales methods which meet the foreign buyer on his own ground.**

Of seventy automotive concerns manufacturing and selling all lines of equipment, a recent survey showed that fifteen only could provide foreign language literature for their products. Yet, each of the seventy was interested in foreign trading and is trying to obtain export outlets.

Service

What would be revealed in a similar survey devoted only to service and maintenance literature can only be imagined. One company, for example, which has placed its cars throughout the world, was unable recently to find a wiring diagram showing its models equipped with magneto ignition and it had not thought of the necessity of furnishing any diagrams at all, except in English, to its foreign distributers.

Service, in the export field, is even more important than at home. But this subject has been discussed numerous times and further reference need not be made to it, except the statement that future developments should stress this more strongly than perhaps anything else. The well-serviced car will be the one with the greatest sales in foreign countries and the exporter who devotes the proper attention to maintenance and upkeep will find himself amply repaid in increasing business and expanded profits.

For the coming year, the automotive exporter must keep himself in the markets. During a period of depression, this may be more or less of a thankless job, but one he must go through. Otherwise, when he attempts to regain his former standing, undoubtedly he will find the market closed. Those companies which have been longest in the foreign field are not abating their efforts in the slightest. One export company, notable among the American sellers of passenger cars abroad, has even increased its sales and advertising departments during the last month. Its traffic and accounting departments may employ fewer men than they did six months ago, but the sales and advertising divisions are stronger to-day than they ever were. That company means to keep the markets it has gained; it has confidence in the future of the automobile throughout the world.

Shows

In the next six months numerous shows and demonstrations have been arranged. Although few manufacturers would allow any of their dealers to keep out of any domestic show, regardless of the size of the place in which it is held, they have generally paid little attention to foreign exhibitions. A show is scheduled to be held in Mexico City in March. The Witwatersrand exhibition in South Africa was so successful last year that it will be repeated again in the same month and, following in April, May and June, at least eight or ten agricultural exhibitions will be held in different places throughout the Union. Some of these will be small, but each is a potential sales place for cars, trucks, tractors and other equipment.

A calendar of coming expositions shows many others, such as the Lima centennial exposition and the Indian tractor trials. Some are out and out motor car shows and others are the annual exhibitions of district or national agricultural societies. There are many of these societies

*Managing Editor El Automovil Americano.

in Latin-America, Spain, South Africa, Europe and elsewhere and most of them hold an annual exposition or fair. Even Bulgaria is planning a forthcoming exhibition, and extensive tractor trials, under governmental supervision, are to be held in India.

Naturally, the American manufacturer should be a leader in the promotion of the show idea. Outside of Europe and a few of the larger centers, the exposition plan has not penetrated far in the overseas territories. But it has been a business builder in the United States and it likewise will be a business builder in other countries.

Highways

The promotion of road building is an opportunity that but few makers have even considered. In the more undeveloped territories of South America, Australia and South Africa, and the Far East, there is already a great deal of road interest and it only needs a push to start the improvement of a large mileage of highways, with a resultant gain to the automotive industries that will dwarf all the difficulties and costs of the campaign.

In fostering foreign road campaigns, particularly in South America, the first thought needed to be put across is that the macadam, concrete or asphaltum road is not the only construction for solving communication problems. Many communities are holding back any highway improvement until they can have the best. But the automotive industry certainly knows what has been done in our own Middle West with the graded dirt road that may be improved at surprising small cost.

The graded dirt road will answer many of the needs of Latin America. It can be quickly and easily built at small cost and with widespread benefits. But it must have a champion and that champion should be the automotive exporter. Where roads do not exist at all, as in many parts of Argentina, Brazil, Chile and elsewhere, some sort of a highway should be cut through between the different cities. If these are graded and properly drained there are roads suitable for traffic nearly the entire year.

The problem in the Argentine is merely one of rain and drainage. Three-fourths of the country is without stone and is level and flat. Many of the provinces have no frost, and thus one of the major enemies of good roads is removed. The ease with which roads can be improved in such districts certainly should cause exporters to bend every effort to further highway projects.

American Cars

The American car lines are stronger to-day than they have ever been before for going after foreign business. The New York show dispelled any doubts that may have been entertained on this subject. The almost universal betterment of finish and workmanship and the more careful manner in which the cars were built should prove an important step forward in the export trading of American manufacturers. The cry against the American-made products has been that they were poorly finished, that colors were badly put on, that upholstery was inferior, etc. Perhaps there was some merit in these contentions when they were first made, but they should no longer hold. Now that the market has been turned into one in which production is not the only problem, the cars themselves should certainly disprove any such statements. The show revealed that more careful assembly and inspection had become the rule and it also showed that the manufacturers were ready to go further in meeting the demands of the individual customer.

Certain of the foreign markets have their individual requirements in such details as color and finish, ignition, steering, etc. Manufacturers are offering more color options to-day than they did a year ago; in fact, many companies announced themselves ready to furnish any color wanted. The number of makers refusing to fit magneto ignition and right steering is smaller than it was a year ago. Wire wheels were shown on a larger number of models—and wire wheels are desired equipment in many places.

All of these options, which have nothing to do with anything except the individual wishes of buyers and are not determined by the excellence of one kind of equipment over another, indicate that our companies are better prepared for the foreign trade fight that is to come. And it will be a fight, particularly on the higher priced cars. These markets can be held only by salesmanship of the highest type. Service, undoubtedly, will be the backbone of this salesmanship and next in line with it will be the attempt to give the buyer what he wants. He is, after all, the deciding factor in any business transaction and his wishes rather than those of the sales manager, the vice-president or even the president should be respected. That is sound salesmanship, in the foreign as well as the domestic markets.

To illustrate: One of the larger companies brought out its 1921 line early last fall. As its foreign business is large, its distributer in one of the Central American countries was immediately sent a shipment of the new models. The first cars sold readily, as the line was one of the larger sellers in that particular territory. Then sales stopped. The investigation which followed revealed that the tops did not stand up under the hot sun of this Central American country. The composition material became sticky under the heat and the Central American buyers did not like them, although they are entirely satisfactory in the home climate. The job itself was one of large production and to furnish different tops for the hotter climates puts the company to quite an expense. But the adjustment was made and the buyers of this particular car in the warm countries will not have to worry again over the durability of their tops.

This was good business. If the change had not been made quickly, the line would have lost an attractive market. But, judging from past events, how many manufacturers would have seen the wisdom of such an adjustment?

Mechanically, then, the American car lines—and likewise trucks, tractors and accessories—are suitable for all markets, or can be made so, if the manufacturer has the proper conception of building up his overseas trading. What are the other drawbacks to immediate business?

Cars in India

A BRITISHER just returned from India has been drawing attention to and indorsing the remarks of the newspaper *Englishman*, of Calcutta, on the big hold of American cars in British India. The figures quoted are from the Department of Statistics of India. They show that 1041 motor cars were imported into British India during September last, and of these 723 cars were consigned from the United States and 247 from the United Kingdom. During the six months April to Sept., 1920, the number of motor cars imported into British India was 7498, against 2553 cars in the corresponding period of the previous year. *Of the* 7498 *cars above referred to,* 5654 *were from the United States,* 1002 were manufactured in the United Kingdom, Canada recorded 532, France 49, Italy 43.

The increase in the imports for the six months of 1920 over the same period in 1919 is striking, and would indicate the rapidity with which the car is replacing the horse for vehicular traffic. A striking feature also is the poor show the imports from the United Kingdom make, and the relatively good position held by Canada.

Transmission Efficiencies

Editor AUTOMOTIVE INDUSTRIES:

The writer was very much interested in reading the above editorial, which appeared in the Jan. 6th issue of your paper.

The writer has been conducting extensive tests in the laboratories of the Joseph Dixon Crucible Co. with truck transmissions to determine the efficiencies of various lubricants, and the results obtained have been such as to confirm the results described in the paper recently presented to the American Society of Mechanical Engineers.

The tests conducted by the writer were such as to preclude, as much as possible, any errors in observation, since each test was repeated several times, and both the electrical and mechanical readings were employed as a counter-check.

Two different types of transmission were used in the tests conducted by the writer—one, a heavy truck type, which was apparently identical with the one described in the A. S. M. E. tests. This transmission is of a conventional design, with the constantly meshed gears located at the forward end of the transmission and the secondary shaft is arranged in the same horizontal plane as the primary shaft. The other transmission tested by the writer was a lighter truck type, with the constantly meshed gears also at the forward end, but with the secondary shaft below the primary shaft.

It was demonstrated in both cases that the direct drive is slightly less efficient than any of the lower gears, whether the secondary shaft is located in the same horizontal or the same vertical plane with the primary shaft. The difference, as may be expected, was slightly more pronounced in the two shafts in the same horizontal plane, but it was very clearly demonstrated that the greatest proportion of the power losses is due to the churning of the lubricant.

It is, of course, evident, that the churning effect of the secondary shaft is identical whether running in direct drive or in low gear, but the fact that the remaining gears of the primary shaft, except the constantly meshed gear, are running at lower speeds when in low gear, will readily account for a difference in the churning effect. This is due to the fact that all the gears of the primary shaft are running submerged in the lubricant to about one-third of their circumference, since the normal filling of the transmission case has to be approximately to a level flush with the underside of the primary shaft. If the level of one lubricant is below this line, it would be difficult to properly lubricate the anti-friction bearings employed.

In order to check the perhaps unexpected results of the extraordinarily high power losses, due to oil churning, a number of very interesting experiments were conducted by the writer with the lubricant drained from the transmission with sufficient lubricant clinging to gear teeth and bearings to prevent damage during the test runs. The results obtained showed very clearly that the power losses under these conditions were only a small fraction of those run with the case filled with oil. The data obtained, together with those of other tests, have made it possible to determine fairly accurately the effects of the different elements which contribute to the power losses in an automobile transmission.

The value of the test observations was enhanced by the fact that test runs were made at different temperatures, and, as was to be expected, the effect of the churning resistance of the lubricant at lower temperatures was particularly noticeable.

The writer feels that it would be of interest to you to be informed at this time of the results of his tests, which will be presented to the Engineering Fraternity in complete form as soon as some final check tests have been completed and the very extensive material has been properly digested and interpreted.

I should appreciate very much to receive your advices as to contradictory results of previous experimental evidence, but I believe that such evidence is not very conclusive in view of the fact that the majority of previous transmission tests were not conducted under the strict scientific precautions which conclusive efficiency tests require.

It is the writer's opinion that a thorough examination of the present transmission designs will demonstrate very clearly that there is considerable room for improvement in the design of our present type transmissions, especially from the standpoint of satisfactory lubrication.

Smaller Engines to Better Fuel Economy

Editor AUTOMOTIVE INDUSTRIES:

I was very much interested in reading your editorial in the Jan. 20th issue on "Effect of Weight on Fuel Consumption." I believe that the last sentence in your editorial strikes a keynote, and which is a thought probably apart from the rest of the story, in which you state, "The chief reason why the light car consumes less fuel than the heavy car is due to the fact that a smaller engine can be used."

I believe that we should all work toward smaller engines, in order that we can obtain the best possible efficiency out of our power plants. We are all aware of the fact that the Otto Cycle is very inefficient at light load, and only shows real results when operating at, or near, full throttle opening. A comparatively small engine can be used if we decide that high speed can be sacrificed. Forty miles an hour should be fast enough for the average person. With a small engine, geared so as to give this as the highest speed, instead of sixty or better, we will be operating the engine at nearly full throttle a greater portion of the time. We might have to sacrifice slightly in acceleration ability, but refined design can combat this to a large extent.

The problem of manifold distribution is most serious at partial load while the full-throttle opening condition can be easily coped with. We find that trucks with a

(*Continued on page* 282)

The Relation of Cost of Labor to Factory Product

The marked need of stable definitions of labor cost, also of more intelligent compilation of cost data before adjusting sale arrangements on this basis are here set forth. At present, efficiency of labor does not figure in results. All factors included in labor cost must be determined.

By Harry Tipper

THERE is a great deal of misconception even among the heads of industrial concerns about the cost of labor and its relation to the total cost of the product. In this case, of course, labor is used to indicate the labor employed in production, it does not include the labor necessary for office work, sales executives and other departments of the business not concerned with the actual production effort.

A great deal of loose conversation has been made in and out of publications, and in and out of committees in various industrial establishments. Orders have been handed to production managers from the final heads of concerns instructing such managers to put into effect a reduction of wages on the basis that it would provide a reduction in costs on a given proportion without having first examined the proportionate amount of production labor required in relation to the total price of the product.

In one concern where the production manager has gone through various experiences with cost accounting and arrived at a system of cost analysis which appears sufficiently accurate and informing, **this manager was instructed to reduce wages ten per cent because the product had been reduced ten per cent in its price. He had the matter looked up and found that the effect of a ten per cent cut in the wages was equal to a one and one-quarter per cent cut on the sales price of the article.**

The actual amount of factory labor required in the production of a given article depends upon the character of that article, the character of the machinery and equipment involved in its manufacture and the character of the process.

It is true that in connection with all industry and using the term labor in its broader sense a very considerable portion of the final cost is taken up by the cost of labor, but this does not obtain when the term labor is used to discriminate factory labor, as is quite customary, and when single industries or establishments are dealing with their own particular part of the labor problem.

A number of the statements made by otherwise responsible men in industry handling matters of considerable importance either from the financial or production end, indicate the superficial character of the study which has been given to the subject of labor costs and the division of those labor costs in the departmental activities of the company involved. It is rarely the case that the cost of the labor in the factory per piece amounts to more than 40 or 50 per cent of the total sales price of the product.

The total labor required for the final sale of the particular article, including the manufacturing labor, the labor involved in designing, planning, accounting, office routine, demonstrative overhead and sales may reach very much larger percentages of the amount involved in the sales price of the article.

Many manufacturers have spoken as though the reduction of a given per cent in the price of their manufacturing labor would permit a similar reduction in the sales price, although obviously the labor percentage is only a proportion of the total and may reduce that proportion cost by half the percentage reduction in the sales, one-quarter, or in some cases one-tenth.

It is somewhat idle to discuss the exact effect of an increase or a reduction in the wage rate as arising out of a necessary reduction in the sales price, until the cost of that proportion of the labor affected is determined in terms of the sales price itself, and this is particularly the case when the efficiency of the labor is not considered at all in connection with the reconsideration of the rate.

This is just an indication of the amount of practical work required in the analysis of cost in order to arrive at a proper understanding of what is involved in the actual pay-roll pertaining to the different process of manufacturing and selling a given article.

In some products, where the cost of the product itself is very low and the labor required to handle is small, a very large proportion of the sales price may be the cost of selling, packing and physically distributing the product in question. In this case, a reduction in the amount of pay for the workers in the factory would have to be absurd, in order to meet a small reduction in the cost of the article itself.

In some special articles the value of the product is less than 5 per cent of the total sales price, the value of the package represents about 45 per cent and the value of the labor in manufacturing only 10 to 20. A reduction of 10 per cent in the sales price in this case would require a reduction of 50 per cent in the manufacturing labor rate in order to equalize the cost variation.

No solution of the question of labor costs can be secured from examining it from this standpoint alone, and certainly no solution can be determined by the arbitrary reduction of wages without the proper understanding of their relation to the cost of the product to the buyer.

This brings up again the question of what is involved in the labor cost, and what relation it bears to the labor rate which is paid in the plant. It also involves the question of what is meant by labor. This word is used to describe many different sections of the labor necessities included in the manufacturing establishment. It may be

used to indicate the total labor required outside of those officers of the corporation who are elected by stockholders. It should be used to include all labor involved in the manufacturing and sale of the article no matter whether the labor is executive or subordinate, or whether it is mental or manual. It is most frequently used, however, to describe the more or less manual labor included in the manufacture or the actual production of the articles which are made by the factory and which come under the variable wage scale.

The confusion which exists in the discussion of labor costs arises very largely from a lack of definition as to that operation of labor which is being referred to in the discussion and the relation which that part bears to the total labor costs involved in the particular establishment.

The conditions surrounding the manufacturing process in the particular establishment are rarely indicated in connection with the discussion of labor costs, and therefore the reasons for their importance or lack of importance are not made a part of the discussion itself, and cannot be considered in drawing conclusions therefrom.

The subject is one which is discussed so frequently in public and semi-public prints or meetings, that the indefinite character of the discussion is particularly unfortunate. As a matter of fact, the analysis of costs has not gone sufficiently far in its consideration and definition of the items under which the costs should be placed, and the proportionate importance of the labor in connection with such costs. In very few cases is the analysis between manufacturing costs and distribution costs clearly determined, and frequently there is little attempt to differentiate between the accessory costs to manufacturing not included in the actual production, but necessary to the production and the accessory costs to distribution and marketing not involved in the direct operation, but required for the completion of the operating necessities.

The cost analysis which has been considered and developed in a great many lines of business has been limited in its scope as a rule, and has not been of sufficient value to the manager and engineer who are concerned with determining not only the amount per unit, the effect of the variables per unit, but the accessories, the comparative importance of all the different elements necessary to the completion of the production or the accomplishment of the final sale.

The discussion of the cost of labor has not dealt with the average efficiency of the laborer at the time that the cost was determined, the effect of the variation in the efficiency upon the cost, the relation of the total cost per unit to the variation in the hourly rate and other matters which would be considered absolutely necessary in determining values of material or equipment.

There is so much misunderstanding already on the subject of labor costs that only careful definition of the particular cases involved will lead the discussion into more practical considerations of the subject, the factors which must be considered in its operation and the relation which it bears to general prices, in the particular cases which are being considered.

At any rate, the present loose and indefinite discussion does not help the solution of the situation and merely adds to the confusion by increasing the misunderstanding.

Selling the Sales Force to the Workmen

SEVERAL hundred salesmen of a Western automotive concern gathered for convention at the factory—salesmen representing the "pacemakers" in the sales force. While these men were holding their meetings and gatherings of one sort and another each was given a badge which he was told to present to a certain workman in the shop. Each salesman met a specified worker or group of workers and these workers took the salesmen through the shop and explained the plant activities and working processes.

On the face of it, this was solely for the purpose of familiarizing the salesmen with the plant. But it had a much deeper significance. It was, in fact, an effort to "sell" the sales force to the factory.

In many plants the workers are utterly unfamiliar with the things that the salesmen do. This plan was devised by the S. F. Bowser & Co., Inc., to overcome such a condition. Workers are apt to think that selling goods is a snap job; that a salesman needs merely to go around and take orders. And they may also feel that they alone could run the plant and distribute the goods without the aid of executives or salesmen. Consequently, there was a distinct educational value to these workers to find out just what is required of a salesman and just how hard salesmen have to work in times like these when business comes with difficulty.

In the Bowser plant paper is a department headed "Our Inquiring Reporter." In this particular issue the inquiring reporter asked a number of employees "What do you consider your most interesting experience since being employed at Bowser's?" This is the answer given to this question by Eugene Wells, an employee in the plant working in department 14:

"The sales convention was one of the most interesting occurrences since my coming to Bowserdom. It was at that time that I was seriously impressed with the fact that we in the shop are utterly dependent on the sales force and they on us.

"At that time they wanted us to 'hurry up' production to fill all the orders they could sell, and now that the much-talked-of after-war readjustment of prices is upon us, it is incumbent upon each of us to 'hurry-up' production as much as possible in order to cut down unit cost and thereby enable the salesmen to make sales that they might not be able to make at war-time prices, and incidentally keep the wheels turning here in the shop and all of us on the job as usual."

Smaller Engine to Better Fuel Economy

(*Continued from page* 281)

load gives greater ton-miles per gallon of fuel than do passenger cars. We also find upon analyzing the exhaust gases of trucks, that more complete combustion is obtained. These results are due to the truck engine operating at full-throttle the greater portion of the time.

The obvious conclusion is to endeavor to control these favorable conditions that we know of and the answer is the use of the small engine. AUSTIN M. WOLF.

A TEXTBOOK of rather elementary character dealing with ignition systems used on automotive vehicles has recently been published by the McGraw-Hill Book Co. under the title Automotive Ignition Systems. The authors are E. L. Consoliver and G. I. Mitchell.

Minimizing Starting Difficulties

MUCH attention has been paid in recent years to various methods of heating inlet manifolds as a means of securing better vaporization of fuel, and it is now quite generally conceded that even the high end-point fuels now available can be successfully handled by this means. During the starting period, however, no exhaust heat is available. A choke or primer is usually employed to furnish a great excess of fuel in order that a sufficient amount of the lighter fractions to form an explosive mixture at low temperatures may be had. Only a small part of the raw fuel drawn into the cylinders is vaporized and much of the remainder finds its way past the pistons to dilute the lubricant in the crankcase. The detrimental results of this dilution are well known, and the waste of fuel is appreciable though small in comparison to other fuel waste to which we have unfortunately become so accustomed.

There are two means of pre-heating available. A small amount of fuel may be burned in such a way as to heat the inlet passages, or an electric heater can be installed which will at least partially vaporize the fuel used during the starting and warming-up period. If fuel is used for pre-heating it must be ignited by a spark, hence electrical apparatus and more or less other complications are added to a system already complex. Nevertheless, the problem is worthy of more study than it has been given, and it should be receiving study for the troubles incident to dilution of lubricant, and the difficulty of securing a quick start seem certain to increase as fuel becomes less and less volatile.

When means of properly heating the charge once the engine is started are provided the actual start can be greatly facilitated by the use of a small quantity of very volatile fuel such as ether as an alternative to other aids in starting. This involves the use of a relatively simple priming device, and may prove the best solution of the problem. Priming should, however, be used so far as possible without resort to the choke if the evil effects of lubricant dilution are to be avoided.

An incidental but by no means unimportant benefit to be derived from any method (except the use of an electrical heater) that makes for prompt starting is the lower demand that will be placed upon the battery. This constant source of difficulty can be made less annoying by anything that tends to keep the battery fully charged—an argument which does not, of course, favor the use of purely electrical means for aiding starting.

Speak for Economic Government

AN increasing number of automobile and truck manufacturers are becoming interested in export trade. To these manufacturers the figures showing the extent of this trade, issued monthly by the Federal Bureau of Foreign and Domestic Commerce, are of intense interest. It will probably be very interesting to these manufacturers to know that the issuance of these figures is endangered because of a lack of money to maintain the photostat department which prints the data. It also should be interesting to automotive manufacturers to know that the Patent Office is steadily losing its best men because they can earn several times as much as their Federal salaries in private work. This great and useful office is far behind in its work; its records are poorly kept and there is no remedy under the present system of appropriations. The fact that the Patent Office is self-supporting apparently has no influence on Congress. The receipts of the office are turned into the United States Treasury and the Commissioner of Patents must beg for appropriations, just as do the heads of non-productive bureaus.

Of course, we are all for economy in governmental affairs. But economy does not always consist in not spending money. It is the wise spending of money that should be sought. These two bureaus of the Government are useful and necessary institutions. They are worthy of support.

It would be a very wise precaution for manufacturers to write to the members of Congress from their states demanding support and economic man-

agement for the useful functions of the Government. There are other very worthy Federal institutions, among these being the Forest Products Laboratory to which we referred on this page a few weeks ago, and the Bureau of Standards.

It is surely a duty of the engineer and manufacturer to speak out on these things at this time. Write your congressman and senators to-day and we venture you will be surprised at the nature of the replies you receive.

Helps Patent Office Service

THE Conference Committee of the Senate and House of Representatives has recommended for favorable action House Bill 11984, known as the Nolan Bill. This bill carries an upward revision of the salaries to be paid to employees of the Patent Office, the intention being to make it possible for this office to hold some of its men longer than at present.

The bill, as recommended for passage, fixes the salary of the Commissioner of Patents at $6,000 a year. This office, besides being that of the executive of the Bureau, is often compared with that of a judgeship. The Commissioner sits as judge in patent hearings, which are the equal of many cases tried in the regular courts.

The passage of this bill undoubtedly would be a forward step for all of those interested in patents. It means a check in the present expensive labor turnover in the office—this turnover being expensive to all who are financially interested in patents. The time remaining at this session of Congress for passage of the bill is very short. If you are interested in improving patent office service, write to-day to the Congressmen from your district asking them to call up this bill and to support it with their votes.

There is a great need for this legislation.

Power and Moral Obligations

THE argument against any sort of democratic control in industry is largely based upon the lack of efficiency which would probably result. But the argument in favor of the present form of control through benevolent, or some other form of autocracy, rests almost entirely upon the assumption that the power in the hands of employers will for the most part be so utilized and administered as to operate industry for the best interests of society and in such manner as to render the best service to the community.

Consequently, the responsibility of each individual manufacturer to so administer the part of industry under his control is great. It presents to him an especially difficult problem for practical solution when business conditions are unfavorable and there is a strong temptation to disregard for the time being those moral obligations upon which the interdependent units of modern industry fundamentally rest.

There is a certain obligation that every manufacturer owes to every other manufacturer. Without a widespread conception of this moral basis of industry, business and manufacturing cannot successfully go on. Not long ago a parts maker wrote to one of his customers, stating the difficult position in which he was left by indefinite suspension of orders and calling attention to the necessity for recognizing the moral phase of the situation in endeavoring to formulate some plan by which an adjustment might be made which would be fair to both parties.

The reply to his letter ran something like this: "We have looked at our own situation and the situation with us is precisely the same as it is with you. Our customers have backed up on us. We in turn back up on you. You in turn back up on your material supplier, and so it goes." And the reader might be justified in reading the writer's thoughts to add, "And devil take the unfortunate company that has no one else to back up on." Were this idea to prevail, modern industry could not survive successfully, because it is made up of strongly interdependent units which must recognize toward each other certain fundamental moral obligations.

In like manner, there is a similar obligation between employer and employee. The economic power in the hands of the employer, which is especially strong just at this time, needs to be wielded in a just and calm manner. Where wage reductions are necessary, they should not be in the form of reprisals. It is at a time like this that the real test of the essential soundness of our present industrial system is made.

The China Famine Fund

IT has been suggested that the business papers should suggest to readers the great need of millions of Chinese for food to avert an unprecedented death percentage in that country.

This movement is not a part of the Hoover movement for feeding the children of Europe. The need in China is based on bad crop years, due to drouth and other features over which man has no control. There can be no question as to the need.

No question as to whether any man should share his plenty with others should arise. If you can spare something from your means, it is your duty to help others. If you care to justify any gift of this sort by economic arguments, think of the economic value of a human life, also of the trade prospects of a friendly China with her millions of people. The treasurer of this fund is Vernon Munroe, Bible House, Astor Place, New York.

A REVISED code of ethics was adopted by the American Society of Mechanical Engineers at their recent meeting in New York City. The second item in that code is worth the attention of every manufacturer and executive. It is as follows:

"His (the mechanical engineer's) first duty is to serve the public with his specialized skill. In promoting the welfare of society as a whole he advances his own best interests as well as those of the whole engineering profession."

In this brief quotation is contained an excellent statement of the modern conception of the basis and purpose of industry.

Chicago Show Starts Midwest Trade

Sales Approximate Two-thirds of 1920

Attendance Records Show Wide Public Interest—Rural Buying at Minimum

CHICAGO, Feb. 5—The New York automobile show established the fact that the buyer had returned to the market. The second national show held in Chicago during the past week further proved it. Shows which have been held in other cities in the intervening time likewise bore evidence of it. With reference particularly to Chicago, buying has returned where little real business has been transacted for the past two months and it has returned with great enough vim to lead the dealers to believe that with continual, effective pushing it can be carried on through the year.

From every standpoint of the distributer and dealer the Chicago national automobile show was a success. While the actual retail sales made on the floor were not as great as during the same period a year ago, reaching possibly 66 2/3 per cent of that figure, the great attendance and the unusually large number of live prospects obtained fully justified the optimism which the selling organization felt from the time the doors of the Coliseum and First Regiment Armory opened until they closed a week later.

The paid attendance, despite unsettled weather conditions—a few days of rain and other days that were threatening,—was 18 or 20 per cent better than last year. With the exception of the opening day practically all admissions were paid. The booths were so crowded the middle of the week that it was impossible for the selling organization to do really effective work.

Prospects Increase 50 Per Cent

In estimating that the list of prospects is far greater than during the same period in 1920, perhaps 50 per cent greater, there is taken into consideration only those prospects who showed a real interest. Dealers doubtless will find as has been the experience at other shows that one list will probably contain the names of prospects whose names are possibly on half a dozen other lists.

There were comparatively few buyers or prospects, as compared with last year, from the rural districts embraced in the Chicago distributer's territory. The number of country dealers showed a slight decrease. Dealers who did not come have fallen into the state of mind revolving about depressed conditions at home. Selling campaigns will shortly be projected by Chicago distributers to bring the dealers in the country to a different way of thinking.

Distributers feel from the out of town attendance of prospects and dealers that business in the agricultural states inclusive of Illinois will continue to remain in a quiescent state unless real merchandising efforts are brought into play. In spots there already appears to be an easing up among the farmers. Financial pressure by the banks is likely to cause grain selling soon.

(*Continued on page* 290)

Car Demand Steady in New York District

NEW YORK, Feb. 5—Metropolitan dealers find much encouragement in the steady tone of the market at the close of the first week of February.

There is every indication that the selling momentum gathered in the New York show, early in January, has been lasting and that a gradual increase in buying may be expected for the next few weeks.

Particular significance is attached to the fact that business in general along the row is nearly 100 per cent better than last October and November and considerably better than December, and it is pointed out that in addition to this the "spotty" business of January has settled down to a steady demand for cars day by day.

Wellborn Sees Return of Trade in South

ATLANTA, Feb. 5—That business has already greatly improved since the first of the year, inflated credit reduced, and is assuming a stabilized condition, and that the present outlook portends better and brighter times for all lines of business throughout the South, is the opinion expressed here in an interview by M. B. Wellborn, governor of the Sixth District Federal Reserve Bank.

The opinion is based on a survey of conditions made by the bank officials of the Southeastern states comprising the Sixth Federal Reserve District. Wellborn stated that the deflation period has about passed and that normal conditions are gradually returning.

GRAY-DAVIS SELLS LIGHT

BOSTON, Feb. 7—H. C. Dodge, Inc., has become the owner of the house lighting system formerly marketed by Gray & Davis, Inc. This plant is known as the "D-Light House Lighting Unit," and the company expects to manufacture under conditions which permit a larger volume of production under the supervision of a staff of engineers and high-grade mechanics.

Tire Dealers Form New National Body

Cleveland Selected as Headquarters—Seek Co-operation of Manufacturers

CHICAGO, Feb. 5—The National Tire Dealers' Association has been organized here following a three days' session of delegates from ten cities where local associations have already been established. Cleveland was selected for the national headquarters and Phillip O. Deitsch of that city was appointed secretary.

The purpose of the association, according to the constitution, is to advance and safeguard the business interests of tire dealers and to promote a co-operative relationship between the manufacturer, tire dealer and buying public.

A resolution was adopted defining the legitimate tire dealer.

"Whereas," it says, "we believe that the policies of a great many manufacturers have been unethical with reference to their interpretation of legitimate tire merchants, therefore be it resolved that this association consider a tire merchant to be one who sells tires at retail and whose policies are not dictated by any manufacturers. The definition of a tire merchant shall be as of firms having a permanent place of business, making their major profits from the sale of tires, tubes and tire accessories; also repair men and vulcanizers and such owners of garages who carry a stock of tires and tubes for resale."

Another resolution was adopted relating to the mutilation of used tires.

Would Stop Tire Frauds

"Whereas," it reads, "it is the practice of some unscrupulous tire dealers to repair and replace upon the market worn-out tires, be it resolved that this association recommends that its members mutilate by cutting in two all junk tires just before disposing of said tires to anyone so as to render them unfit for further service."

Another resolution was passed recommending that manufacturers take some similar action.

The officers elected were as follows: President, Thomas F. Whitehead, Chicago; vice-president, R. F. Valentine, Cleveland; treasurer, Henry Stenzel, Milwaukee. The directors in addition to Messrs. Whitehead, Stenzel and Deitsch are Edward P. Farley, Minneapolis, and A. B. Clark, Kansas City, for one year; Joseph Roberts, St. Louis; R. J. Walters, Baltimore, and R. R. Woolley, Cincinnati, for two years.

Protests Stir Anti-Dumping Action

Propose Sales Tax to Equalize Prices

Revision of Internal Revenue Act Shown as Way to Correct Uneven Competition

WASHINGTON, Feb. 7—Nation-wide protests against the dumping of surplus trucks, sold by the Army to foreign dealers, on American markets have brought about a proposal to amend the internal revenue act at the next session of Congress in order to afford protection to domestic dealers and manufacturers. Congressional leaders believe that this unfair competition may be checked through the enactment of fiscal legislation which would impose a sales tax on trucks and other automotive equipment sold by foreigners or their American agents, to equalize the excise and sales tax levied on local manufacturers and dealers.

The California delegation in Congress has been advised that the Slough Trading Co., an English organization, has taken advantage of customs regulations which permits entry of American-made goods free, to invade the market with several thousand war trucks. Sales agents of this organization, it is said, have been active in Los Angeles, where 75 trucks have been offered for sale at prices which defy competition.

Los Angeles dealers assert that prices are inflated for a time until a real prospective buyer appears and attractive discounts are offered which prohibit competition by other dealers. It is further claimed that these former Army trucks, remodeled or refinished in British shops, return without imposition of duty as "used" machines while they are later offered as new trucks.

Tariff Change Ineffectual

California congressmen have inquired as to the possibility of revising tariff duties, but found that the law could not be changed in this respect without meeting defeat as class legislation. Treasury officials thought it would be possible to offset this disadvantage by revision of the internal revenue act when it is called up at the special session next month.

There seems to be a good chance that this proposed legislation will be favorably received by committees and ultimately by Congress because the incoming legislative and administrative branches of the Government are committed to a policy of protection. It is stated that American manufacturers will co-operate with dealers in this measure in order that domestic markets may be protected.

The trucks were sold to the War Department, and an agreement was reached after the armistice that these machines would be sold abroad rather than disrupt American markets by their return and subsequent sale. The War Department kept to its bargain and sold to British and French dealers. These dealers repaired the trucks and cars and propose to reship them to this country. The exchange situation, free entry and the low costs make it possible for them to deliver these American-made foreign-owned trucks to American agents at prices far below current quotations for domestic products.

Depressive Effects Feared

Under existing tariff laws, American dealers and manufacturers are quite helpless to prevent the dumping at cut-rate prices, often below the production costs. The depressive effect of the Anthony "rider" to the Army appropriation bill, which would compel the sale of 10,000 trucks coupled with this latest menace to resumption of domestic sales, is expected to bring about unity among dealers and manufacturers in support of proposed amendments to the internal revenue bill.

The amendment, if adopted, would undoubtedly provide for the imposition of taxes on these imported trucks equal to the aggregate tax levied on trucks manufactured and sold in this country. The present Congress will not consider tax legislation, but it will be on the calendar for the next session.

Dealers have been advised this week that French traders contemplate action along lines followed by British dealers.

January Car Shipments One-third of Year Ago

CHICAGO, Feb. 5—Directors of the National Automobile Chamber of Commerce were informed by the traffic committee at their meeting here that carload shipments from the factories during January were 35 per cent of January a year ago, which marks a new low level.

It was decided that the directors would take up with counsel and the N. A. D. A. the recent court decisions regarding confiscation of cars transporting liquor.

The directors expect the recent reduction of 2 cents in the price of gasoline to help sales of cars and trucks.

BICKETT RUBBER ORGANIZED

WATERTOWN, WIS., Feb. 7—The Bickett Rubber Corp. of Watertown, Wis., has been chartered to engage in the manufacture of rubber products of all kinds. The capital is $100,000 preferred and 2000 non-par valued common stock. L. W. Bickett, Max G. Kusel and E. L. Hoge are the incorporators.

House Passes Bill to Sell Army Trucks

Action by Senate Will Decide Big Dumping Move—1000 Cars Included in Order

WASHINGTON, Feb. 8—Ten thousand Army trucks and 1000 passenger cars will be placed on the market within a few weeks unless the United States Senate amends or modifies the Army bill, which passed the House to-day, carrying the Anthony proviso, directing and authorizing the Secretary of War to declare a surplus of equipment and dispose of it on such terms and conditions as he may deem most advantageous to the best interests of the Government. Dealers and manufacturers throughout the country will have but little time to convince the Senate of the depressive effect the passage of this measure would have on the industry, inasmuch as there are few legislative days remaining for the present session.

Congressman Anthony was successful in obtaining favorable action on his measure. He steadfastedly refused to heed the pleas of the highway officials that the equipment be transferred. It was his contention that the road builders had sufficient automotive equipment on hand and could not absorb the trucks and other machines which he wanted sold. A slight revision, proposed by Congressman Mann of Illinois, clarifying the language of the provision, was adopted. The committee had reported "not less than 10,000 of the motor trucks and not less than 1000 of the automobiles owned by the War Department." The Illinois Congressman objected because it could be construed to mean that Congress forbid the Secretary of War to sell less than 10,000 trucks and 1000 automobiles at the same time.

May Sell in Small Lots

Congressman Greene of Vermont stated that the committee's language should be changed for it would not allow the War Department to sell five or ten trucks at a time. This change was subsequently made in the Mann amendment. The question was asked during the debate whether it would be possible to dispose of these trucks. Congressman Dempsey asserted it would not be a difficult matter and it would be possible for the Secretary of War to buy the balance himself, but in the markets.

The bill, as now passed, will be sent to the Senate. If the Upper House objects to this method of disposing of trucks and cars at a time when the domestic market is glutted and other Army trucks are dumped here by foreign dealers, it will be sent to conference.

Willys Corporation in Bankers' Control

Creditors and Stockholders Form Committees to Consider Plan of Action

NEW YORK, Feb. 7—Financial affairs of the Willys Corporation have been placed temporarily in the hands of a bankers' committee and no bills are being paid except with the consent of this committee.

A merchandise creditors' committee is being formed with the sanction of the bankers' committee and efforts are being made to obtain the consent of creditors for an extension of time which will permit of some constructive action.

The merchandise creditors' committee is headed by F. C. B. Page of the E. W. Bliss Co. and the other members include Joseph B. Tarbell of the American Brake Shoe & Foundry Co. and Theodore Beran of the General Electric Co.

A first preferred stockholders protective committee has been organized and it is understood its attitude will not be entirely sympathetic toward the bankers. The preferred stock of the Willys Corporation provides that no mortgages can be placed on any of the company's property except with the consent of 75 per cent of the preferred stockholders. Joseph P. Cotton of the law firm of McAdoo, Cotton & Franklin, is counsel for the preferred stockholders' committee which is headed by Howard Bayne and includes U. N. Bethell, Stedman Butterick, Thomas B. Gannett, Robert E. Hunter, Leclanche Moen and Robert L. Montgomery.

Stock Depositories Named

The depository for the preferred stock is the Columbia Trust Co. of this city and subdepositories are the First National Bank of Boston, the Central Trust Company of Illinois and the Girard Trust Company of Philadelphia.

A similar committee is being formed for the second preferred stockholders. A letter sent to them states that the company needs a large sum to meet contract obligations and commitments in connection with the new factory at Elizabeth, N. J.

The second preferred committee is headed by Arthur O. Choate of Clark, Dodge & Co. The depository will be the Bankers Trust Co. and the counsel O'Brien, Boardman, Parker & Fox.

All the various interests involved are exceedingly reticent as to their plans but it can be stated that reorganization and refinancing of the Willys interests is in prospect although none of the details are available. The subject has been under consideration by the bankers interested for several months. The bank chiefly interested is the Chase National and E. R. Tinker, president of the Chase Securities Co., is a director of most of the Willys units. Walter P. Chrysler, executive vice-president of the Willys Corporation, is directing the negotiations of the company with the bankers. Associated with him in this work is J. R. Harbeck, who recently resigned as vice-president and director of the American Can Co. to devote all his time to his automobile interests. These two men are also directing the affairs of the Maxwell-Chalmers Co.

Definite announcement of the reorganization plan is expected within the next thirty days as many of the corporation's bank loans mature about the middle of March. These loans were renewed at their last maturity date. They are said to aggregate about $20,000,000.

Willys-Overland Not Involved

The Willys-Overland Co. is not involved in any way in the refinancing of the Willys Corporation although 27 per cent of its stock is owned by the corporation. The property of the Willys Corporation includes the Electric Auto-Lite Corp. with a plant at Toledo, the New Process Gear Corp. with a plant at Syracuse, the Duesenberg Motors Co. and the huge new plant virtually completed at Elizabeth, N. J., for the production of the "Chrysler Six," which is not yet upon the market.

The Willys Corporation was incorporated in Delaware in 1917 as the Electric Auto-Lite Corp., and the present name was adopted two years later. In 1919 it acquired the entire capital stock of the New Process Gear Corp. and the Duesenberg Motors Corp. as well as the old plant of the Allen Motor Co. at Fostoria, Ohio.

The corporation has a purchase and sale contract with the Willys-Overland Co. providing for the manufacture by the corporation on a large scale of a new lightweight six-cylinder automobile. This contract provides, among other things, that the Willys-Overland Co. shall market this car through its sales organization and a special unit.

The security holdings of the Willys Corp. include 27 per cent of the common stock of the Willys-Overland Co.; $1,000,000 of the 7 per cent convertible second preferred stock of the Fisk Rubber Co. in which John N. Willys is one of the largest stockholders, and $1,000,000 of the 7 per cent convertible second preferred stock of the Federal Rubber Co. which is controlled by the Fisk Rubber Co.

Capital Stock Outstanding

The capital stock of the Willys Corporation consists of 5,000,000 shares of common of no par value; $15,000,000 of 8 per cent cumulative convertible first preferred with a par value of $100 and $10,000,000 of 7 per cent cumulative convertible second preferred with a par value of $100. All the preferred stock is outstanding and 4,450,000 shares of the common. Of the unissued common stock, 300,000 shares are reserved for the conversion of first preferred at the rate of two shares of common for each share of first preferred and 250,000 shares are reserved for the conversion of second preferred at the rate of two and a half shares of common for each share of second preferred. The company has no funded debt.

U. S. Rubber Shows Higher 1920 Income

Report Earnings at Rate of $19.82 a Share—Inventory Position Good

NEW YORK, Feb. 7—The preliminary report of the United States Rubber Co. for last year shows net profit, after all charges and allowances for Federal, British and Canadian taxes, of $21,275,524, or the equivalent after preferred dividends of $19.82 a share on the $81,000,000 common stock. In the previous year the net profit was $17,730,237, equivalent after preferred dividends to $17.59 a share on the $72,000,000 common stock then outstanding.

The chief items of the income account are shown in the following table:

	1920	1919
Sales	$255,744,685	$225,589,465
Net income	26,925,173	21,396,099
Interest	5,649,649	3,365,862
Net profits	21,275,524	17,730,237
Pref. dividends	5,200,000	5,041,476
Divs. subsidiary cos.	18,718	19,567
Com. dividends	6,480,000	2,098,576
Surplus	9,576,806	10,570,618

In a statement by Samuel P. Colt, chairman of the board, he says:

"The company at no time during the year had any so-called forward contracts for crude rubber, and, therefore, was in a position to take advantage of the low market prices which have prevailed for some months, with the result that at the close of the year your company had on hand and subject to delivery about seven months supply of crude rubber at an average cost of $0.2679 per pound. Therefore, it was not necessary to write off anything on account of crude rubber.

"As to all other materials and supplies, the company had a short inventory position during the latter part of the year and, therefore, was able to take advantage of the decline in prices.

"In accordance with past conservative practice in respect to making reserves, your Directors will in due time consider the advisability of appropriating some part (not exceeding $6,000,000) of the net surplus of 1920 to be set aside as a reserve to take care of any contingencies that might arise."

HALLEYS CLOSES FOR TIME

LONDON, Jan. 17 (*Special Correspondence*)—Cancellation of orders leaving 100 completed chassis on their hands has resulted in Halleys' Industrial Motors, Ltd., Scotland, refraining from making any distribution among shareholders for 1920, despite a fair profit shown by accounts for the year's trading. The directors at a meeting have just announced that no orders were being received to take up these trucks in stock; clearly the outlook is not encouraging. Halleys make one model only, a 3½-ton chassis, which is the only British truck with a six-cylinder engine. Their plant is practically closed down for the time being.

Pierce-Arrow Adds $1,000,000 to Surplus

Company's Position Regarded as Strongly Entrenched—Inventory Losses Written Off

BUFFALO, Feb. 3—Pierce-Arrow company's report for 1920, made public to-day, makes a distinctly gratifying showing for Buffalo's biggest motor car industry. The net earnings after all charges, taxes and depreciations allowances of $1,769,914, or more than twice the annual preferred dividend requirements of $800,000, is considered good in view of the sharp depression which came in the automobile trade in the last half of 1920.

It is true that the balance of $3.88 a share applicable to the common stock is only a little more than half the $6.75 a share earned in 1919—but in that year the automobile industry was at high tide. But the fact that there was a surplus for the year of practically $1,000,000 carried to the balance sheet and that the total accumulated surplus is shown as $4,541,546 is satisfactory testimony as to the way Pierce-Arrow has weathered the trade cyclone.

Inventories are shown as of Dec. 31, 1920, at $16,470,662, an increase over those of the year previous amounting to $2,925,241. The valuation used in making the inventory have been pared to cost and replacement figures. Patents, trademarks, etc., are given only a nominal value and are lumped at "$2."

Quick net assets, aside from inventories, are shown as a total of $3,383,872, of which $1,338,099 is cash. Reserves set up for depreciation of plant, etc., are given as $2,032,784.

President G. W. Mixer, in submitting the report, states that the reorganization of the plant from the basis of its wartime activities has been fully completed and, in making these changes, much has been done to modernize equipment and reduce manufacturing costs.

Processes have been revised for both quality and economy. Mixer adds that some 80 per cent of the tools and machines used in making older models of cars and trucks no longer in active manufacture have been charged off against the previous reserve for depreciation. The plant is now in the best of modernized productive capacity for present and next season's output of models.

Although nothing is said in the report or its presentation as regards present business or indications, it is known the company is getting an increase of orders.

OLDSMOBILE SHIPS TRAINLOAD

LANSING, MICH., Feb. 4—A solid train consisting of 20 cars carrying 60 Oldsmobiles left Lansing this week for Chicago consigned to one of three Olds dealers in that city. The consignee, the North Side Oldsmobile Co., 5206 Broadway, will distribute the entire allotment.

RAILROAD CONCEDES PASSENGERS TO BUSES

RICHMOND, VA., Feb. 5—Representing that motor travel on highly improved highways paralleling its line has seriously affected its passenger traffic, causing this service to be operated at a loss, the Chesapeake & Western Railway Co. has petitioned the Virginia State Corp. Commission for permission to abandon passenger service on the road, it was announced to-day. The railroad is 50 miles in length, extending from Elkton to Stokesville in the valley section, and connecting with the Baltimore & Ohio and the Southern railways. It plans to continue its freight service.

Transit Company Adds New Truck Equipment

DETROIT, Feb. 4—Acason Motor Truck Co. has received an order for 100 trucks from the Red Ball Transit Co. of Indianapolis. The Transit company, according to General Manager W. B. Hiner, plans to greatly enlarge the scope of the work of the company during the year, and inter-city motor vehicle transportation operations are planned between all the larger cities in the country.

The Red Ball Transit Co., which specializes in inter-city overland hauling, was organized three years ago and has been highly successful. The company uses heavy duty trucks with large enclosed bodies resembling moving vans. The main lines now operate to cities between Indianapolis and New York by way of Cleveland on one route and by way of Pittsburgh on the other. There also is a line between Indianapolis and Chicago and another between Indianapolis, St. Louis and Kansas City. The headquarters of the company are at Indianapolis, with a branch office in Chicago.

The company does no local hauling, devoting its attention entirely to inter-city business. It is planned to extend the activities to the Pacific Coast, and sufficient business is on the books, according to Hiner, to justify the placing of 35 additional trucks in operation immediately.

SIMPLICITY FILES PETITION

GRAND RAPIDS, MICH., Feb. 4—A petition in bankruptcy was filed in the Federal District Court this week for the Simplicity Wheel Co. by Attorney Charles V. Hilding. Total liabilities are given as $175,000, and the estate of F. W. French, defaulting cashier of the Grand Rapids Savings Bank and head of the wheel company, is charged with $150,000 of the unsecured claims. Attorney Hilding is petitioner for the wheel company and also receiver for the French estate. Secured claims are $5,242 and the total assets are $36,340, consisting largely of stock in trade.

Miller to Reduce Salaried Employees

Third of Large Companies to Make 10 to 25 Per Cent Reduction

AKRON, Feb. 7—The Miller Rubber Co. is the third tire corporation in Akron to reduce salaries, in addition to flat wage cuts. Notices distributed by the company to all salaried employees, notify them of salary reductions understood to range from 10 to 25 per cent, to become effective Feb. 15. Miller, like practically all other Akron companies, previously had cut wages, hourly rates and piece work rates.

Miller officials in announcing the salary readjustments call attention to the necessity for the step in view of the readjustment of economic conditions, and also advise that salary reductions will be based upon efficiency of service of their employees, rather than enforcing a flat rate of reduction.

"We implore our employees," the notice says, "to recognize the conditions, as the readjustment of the world's business and commerce cannot possibly be made on a lop-sided basis, and while the reduction in commodities has not yet fully reflected to the consuming buyer, as liquidation proceeds buying prices will automatically seek their level. We ask that our employees make every effort possible to adjust themselves to the conditions as they exist, and those who have practiced the extravagances displayed should bring themselves to a realization that thrift and economy, both in personal affairs and in employment duties, will become absolutely necessary. We are adjusting the rates of salaries to equal the service rendered as nearly as possible."

Firestone Increases Hours

Wage readjustments made effective Feb. 8 by the Firestone Tire & Rubber Co., coincident with an increase in factory working hours, are expected to permit increased production without any material increase in cost, it is announced. Firestone departments have been working five hours a day. Under the new schedule employees in the factory will work seven hours a day for the same daily rate as under the five hour schedule, thus giving the company practically ten hours increased factory operation each week, without any payroll increase.

CHAIN OFFICERS ELECTED

MILWAUKEE, Feb. 7—The Auto Life Tire Chain Co., which established a factory at Cedarburg, Wis., several months ago, is increasing production to meet orders from jobbers and dealers. At the annual meeting the following officers were elected: President, E. A. Hoya; vice-president, A. L. Wolff; secretary, William F. Schad; treasurer, F. A. Andree.

Chicago Show Starts Midwest Business

Car Prices Evoke Little Comment —Distributers Prepare for Spring Buying

(*Continued from page* 286)

In a number of instances the matter of price was spoken of by the prospect but this did not figure very materially in the discussions at the booths. General business conditions affected in a large measure the sale of cars that would be bought by wage earners. The buyers of the higher-priced cars have pretty well established positions, and while the purchasers of the moderate priced cars are to a certain extent concerned in readjustments they are not affected as deeply as are the lower-priced car buyers.

That the dealers feel that the show will bring a strong revival of buying, with thorough merchandising efforts inaugurated around the prospects obtained at the seven-day exhibit, is evidenced by the fact that two of the principal distributers of the moderate priced cars have, during the week, received carload shipments of cars. They are forestalling any shortage in supply that the spring may bring.

Detroit Gains Faith in Normal Resumption

DETROIT, Feb. 7—The returning contingent of Chicago show visitors struck Detroit like a breath of fresh air. Detroit has been undeniably pessimistic for some weeks. A great many of those who went to the New York show came back with this pessimism relieved to some extent, but they were not convinced. Practically all those who went to Chicago have come back convinced that business has started on the upward trend.

The beginning of buying by the public will not be felt immediately at the factories, as there is considerable slack that must still be taken up. If the figure of 120,000 surplus cars in the country is correct, this means nearly two months' purchasing at the current rate. Unless buying is accelerated to some extent, the factories will not feel the actual buying until the middle of March. There is sufficient indication of dealer interest, however, to have convinced the average factory that it is perfectly feasible to start on a reasonable production schedule and thus build up an organization that will pick up the load when it begins to be felt.

There have been some great lessons learned during the past year. Manufacturers meeting at Chicago as well as New York discussed these freely. Perhaps the greatest thing that has been learned is the necessity for flexibility in the manufacturing schedule. No one could tell a year ago that business would drop so rapidly as it did toward the end of last year, and bankers' prophecies on this point were ignored. The result is that contracts for parts were made over long periods and for great quantities, working an injustice on the parts maker as well as resulting in piling up inventory at a time when it was very necessary to keep it down.

The parts makers have in many cases asked the car manufacturer to help bear the load. For instance, the Zenith Carbureter Co. has asked manufacturers using their product, where these concerns are well stocked with carbureters, to pass the business along and not let the parts manufacturer hold the bag. They have asked that for every 100 cars made the manufacturer take fifty carbureters. This request has been acceded to in a great many instances and is regarded as a very equitable arrangement.

Highest Production in May

To sum up the situation from the manufacturing standpoint, general production at present is running, leaving out Ford, at about 25 per cent capacity. This may be expected to increase, if one were to hazard a prediction based on general observation, to 35 per cent in February, 50 per cent in April and 60 per cent in May. At this figure it is very apt to remain for practically the balance of the year.

The Ford situation is expected to have a material benefit on the industry, in that a price increase which is confidently expected will be a material factor in showing the public that some of the cars at least are at rock bottom prices. It is a fact that is generally clear to the educated public that some cars are better buys from a money standpoint than others. This is a situation which will have to clear itself, and frankly speaking there are cars that will have to come down in price in order to meet competitors' prices.

From the parts maker's standpoint it is probable that until confidence is restored he will have to work on three-month orders rather than six-month until such a time that full confidence is restored, but unless every sign it is possible to see fails, he will find his shop again producing and his business growing on its merits.

Milwaukee Sales Most in $1500-$2000 Class

MILWAUKEE, Feb. 7—How well the annual Milwaukee show of 1921 functioned as the beginning of the new selling movement, is indicated by semi-official figures gathered from passenger car dealers who exhibited.

An analysis reveals the information that show sales were mainly in the medium and high-priced passenger car classes. More than one-half of the total retail sales were in the class from $1,500 to $2,000, and one-third from $2,000 to $3,000, the remainder being almost equally divided between the $500 to $1,000 and the $3,000 to $7,500 classes. Last year the majority of sales were in the $500 to $1,000 class.

Cleveland Confident of Increased Buying

Factory Representatives at Shows See Indications of Good Normal Business Year

CLEVELAND, Feb. 7—Factory representatives at the New York, Chicago, Cleveland and other shows have come home convinced that there will be a rebound from the low selling and low production conditions that have prevailed, and that the first movement upward is under way.

"The tide has turned and from now on we may be assured that the automobile business will gradually come into normal," said Frank C. Chandler, president of the Chandler Motor Co., upon his return from the Chicago show. "Orders are coming into the factory in better volume than they did in January. January was better than December, and March will be better than February. Later in the year conditions will be even better and I am optimistic about the record that finally will be written around the present year."

At the Templar factory, Daniel L. Britton, factory manager, said the force of workmen would be increased 50 per cent within the next three weeks to take care of increased schedules. Dealers' orders are coming in in such number that larger production is essential.

Peerless and Winton both report that increased output is contemplated. Other manufacturing establishments are putting their equipment in shape in order to take care of orders expected when the trade gets into full swing.

One of the hopeful signs has been seen in the agricultural districts of the State. The farmer has been mighty sore at the drop in prices for farm products, and especially so when he compared these new prices for what he produces with prices demanded for the things he must purchase. Salesmen have been received better lately in the Ohio agricultural districts, according to reports received by dealers.

The reduction in the price for gasoline is another factor that has helped to create an optimistic mood in the industry.

White Merges Working Forces

At the White Motor Co., which has been operating a full day and night force during the period when other plants were either shutting down or greatly curtailing production, a reduction in operations will take place March 1. In the last few months working time has been reduced to five days a week and lately to four days.

Commencing March 1, the night force of 1700 men will be combined with the day force. One force will work three days a week and the other three days. In this way more men will be employed than if the company had adopted the policy of working a single force six days a week.

N.A.C.C. Would Slash Billion From Budget

Taxation Committee Prepares Recommendations on Governmental Appropriations

NEW YORK, Feb. 8—Elimination of the one billion dollar increase proposed in certain Federal departmental estimates for 1922, reduction of a military and naval program to its lowest practicable point, and a further slash of 1 per cent in the estimate, as a first step in a return to "sane, normal conditions," are the major proposals contained in a tax program approved to-day by the directors of the National Automobile Chamber of Commerce. All told, the reductions asked amount to approximately $1,500,000,000.

Other proposals, summarized, include:

Funding of the cost of the war, spreading the operation over a period of 50 years, including therein the floating indebtedness, Victory notes, and war saving certificates which come due in 1923.

Suspension of the program of retirement of the war debt during the period of materially increased expenses growing out of the war or at least until 1923.

Funding of demand obligations of Allies and acceptance of funding securities for unpaid interest which they may be unable to meet.

Repeal of the excess profits, excise, transportation, consumption and other tax burdens growing out of the war.

Provision for additional revenue from a moderate protective tariff.

If still further revenue is required, consumption tax is suggested of 1 per cent on all commodities based on the retail sales to the consumer.

In explanation of the principles proposed and to bear out an expressed conviction that if the major premise of economy is accepted, no further taxes will be necessary, a table of proposed expenditures and estimated receipts for the fiscal year 1922 has been prepared by the taxation committee of the chamber, made up of C. C. Hanch, chairman; H. H. Rice, J. Walter Drake, Charles Clifton and F. I. Barrows. The table is shown on this page.

M. & A. M. A. Committees Named by Directors

NEW YORK, Feb. 7—Committees for the coming year have been appointed by the board of directors of the Motor & Accessory Manufacturers Association. The executive and finance committees, which are identical, are composed of the following: E. H. Broadwell, chairman, Fisk Rubber Co.; C. E. Thompson, Steel Products Co., Cleveland; E. P. Hammond, Gemmer Mfg. Co., Detroit; W. O. Rutherford, B. F. Goodrich Co.; G. Brewer Griffin, Westinghouse Electric & Mfg. Co., Pittsburgh; A. W. Copland, Detroit Gear & Machine Co., Detroit; J. M. McComb, Crucible Steel Co. of America, Pittsburgh.

The show and allotment committee is composed of Rutherford, Griffin and C. H. L. Flintermann of the Detroit Pressed Steel Co.

The banquet committee is headed by McComb and the membership committee by Copland.

FEDERAL EXPENDITURES AND RECEIPTS FOR 1922 PROPOSED BY TAXATION COMMITTEE OF N. A. C. C.

EXPENDITURES		
Total estimated ordinary expenditures 1921		$4,673,395,278
Less item Federal control railroads		1,025,000,000
Total estimated expenditures 1922 if maintained at level of 1921		$3,648,395,278
Urgent Deficiency Item		478,000,000
		$4,126,395,278
Less reduction of 10 per cent as first return to normal standard		412,639,528
		$3,713,755,750
Postal Service payable from Postal Revenue		585,406,902
Ordinary expenses payable from other Sources of Revenue		$3,128,348,848
RECEIPTS		
Internal Revenue:		
Income and Profits Taxes	$2,625,000,000	
Miscellaneous	1,375,000,000	
	$4,000,000,000	
Less loss due to repeal of excess profits	450,000,000	
Less all consumption taxes save tobacco and liquor based on 1921 receipts	$714,386,743	
	$2,835,613,257	
Loss due to reduction in surtax	230,000,000	
	$2,605.613.257	
Plus increase in corporate income due to excess repeal	45,000,000	
	$2,650,613,257	$2,650.613.257
Public lands		2.000.000
Miscellaneous sources		493.000.000
Panama Canal tolls, etc		14,530,000
Total estimated receipts exc. public debt		$3,510,143,257

Reeves Finds Trade in Rallying Stages

Coast Markets Better Than Central Districts—Kansas Credits Again Available

NEW YORK, Feb. 8—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, has just returned from a three weeks' trip in the West, where he addressed meetings of dealers, manufacturers and bankers in Wisconsin, Illinois, Missouri, Iowa and Nebraska. He reports encouraging signs of returning business, although after the spring trade future progress in the automobile industry will depend largely on the progress that other industries make in returning to normal.

Information gathered on this trip, coupled with reports from other sections of the country, indicate that the best trade in cars and trucks at present is along the Atlantic and Pacific Coasts. It is somewhat spotty in other parts of the country.

New York, Pennsylvania, California, Ohio, Illinois and Wisconsin seem to show the best sales, while the poorest sections appear to be through the South, particularly Texas, in the Dakotas, and in Iowa and Nebraska, although with a general upward turn everywhere.

"As in 1914, 1917 and 1919, the automobile shows have marked the return of buying in this country and a change of spirit not alone in our own industry but among business men generally," said Reeves.

"Surveys in the different sections of the country supplied the interesting information that buyers are waiting for lower prices or more stable prices. They want to be sure that prices will not be changed within the next few months. Almost all say they intend to buy another car, and when asked the kind, invariably mention a car of higher price than the one they are using.

"Trade on the Atlantic Coast and on the Pacific Coast seems to be in the best shape. Wisconsin is doing well because her dairy products bring cash every day. Constantly improving trade is reported from Ohio and Illinois. Poor trade is reported from the South, especially Texas, and from sections of Nebraska, Iowa and the Dakotas.

"We find dealers with their houses in order and in the right spirit for a spring sales campaign. They have some grievances against the manufacturers, just as the manufacturers occasionally have grievances against the dealers. That there is a fine spirit of co-operation, however, is evidenced by the acceptance by the directors of the N. A. C. C. of the suggestion by the National Automobile Dealers Association for a conference of committees to review trade conditions to see what can be done in a co-operative way that will be mutually helpful.

"Our meetings with the bankers showed

Improvement Slight in French Industry

Factories Extend Activities — Citroen Cuts British Price— Urge Tax Revisions

(*Special Cable to* AUTOMOTIVE INDUSTRIES)

PARIS, Feb. 5—Only very slight improvement was shown in the French automobile industry during January. No factories were working more than 50 per cent of capacity and in some cases production was as low as 10 per cent. To give employment to the greatest number of men, factories are running only four days a week.

Many firms are meeting present difficulties by getting into other branches of the engineering trade. Renault is making tools and factory equipment. Berliet is building narrow track railroad material.

There have been no price reductions in the French market, but Citroen has cut prices £100 on the British market. The Lorraine-Dietrich factory is practically closed because of the fusion with Clement-Bayard, which makes one factory sufficient to meet the manufacturing requirements of the two companies.

The Austin tractor factory in France has ceased production. Renault has a stock of 1400 passenger cars. The weeding-out period has resulted in the disappearance of several of the smaller concerns. These are Turcat-Mery, Majola, Sizaire-Naudin and Butterosi. Many others are in considerable financial difficulties, but the courts are showing great leniency in not forcing firms into bankruptcy as long as any reasonable arrangement for continued operations can be made.

Some leaders in the industry believe the period of depression in France will last two years. The truck market is glutted with army stocks, there being still 23,000 trucks lying in Government parks and all dealers loaded up.

High car taxation and the high price of gasoline are largely responsible for the passenger car depression. The syndicate of automobile manufacturers has again petitioned the government to relieve the situation by abolishing the gasoline tax, which is now higher than the retail pre-war gasoline selling price, and also to repeal the 10 per cent luxury tax on automobiles.

As proof of the utility of automobiles the manufacturers point out that of 93,115 passenger cars paying taxation last year, 59,492 were officially recognized as utility vehicles and eligible for half-taxation rates.

The French Government aviation credits for the year 1921 total 527,354,645 francs, of which 33,215,000 are subventions for the regular passenger carrying lines, and 11,850,610 for the general budget civil aviation.

One Talbot-Darracq and two Sunbeams have entered for the Indianapolis race, the drivers being Boillot, Thomas and Resta.

Tax Repeal Helpful in Canadian Market

OTTAWA, ONT., Feb. 8—Present activities in the Ottawa district indicate that the automobile business will see good normal sales this year. Price reductions are already announced by certain manufacturers, new models are being placed on the market by Canadian firms and already shipments of several of the new cars have been received by Ottawa dealers. The industry has made rapid recovery from the adverse situation which prevailed as a result of the removal of the luxury tax and as a result of reconstructive developments last fall.

The dealers sustained a personal setback when the luxury tax was removed, but the loss of tax on unsold automobiles in stock at the time that the Government levy was abolished is being absorbed by the manufacturers and the retailers, and this incident is considered closed. An outstanding feature of the Montreal Automobile Motor Show just concluded was the genuine feeling of optimism that prevailed in the automobile trade and otherwise. Every exhibitor and dealer gave evidence of a cheerful tone throughout the trade and the outlook was considered extremely bright by everyone.

Higher Patent Salaries Favored by Committee

WASHINGTON, Feb. 7—The Nolan Bill, which fixes the compensation of employees of the Patent Office, has been reported out of the conference committee and recommended for favorable action. The conference committee accepted the salary recommendations of the House committee, which are about 20 per cent higher than those recommended by the Senate. In this bill the Commissioner of Patents receives $6,000. The time remaining for passage of this bill is quite short and those interested in its success would be wise to consult their Congressmen.

LANDIS MACHINE CUTS PRICES

WAYNESBORO, PA., Feb. 7—Beginning March 1, the Landis Tool Co. will make a general reduction in prices on all machines with the exception of the crankshaft grinding machine. This reduction will average 15 to 20 per cent on the entire line with the exception of the one machine.

Dunlop Management Arouses Disquiet

Dividends for Last Quarter Passed —Two Directors Resign— Arrange New Credits

LONDON, Feb. 5—(*By Cable to* AUTOMOTIVE INDUSTRIES)—The annual report of the Dunlop Rubber Co., Ltd., shows a balance of 1,700,334 pounds sterling, but the directors decided to pass the ordinary dividend and the preferred dividend for the last quarter.

Because of dissatisfaction over the management of affairs, Chairman Ormrod of the board of directors and Director Dawson have resigned. F. A. Szarvasy, chairman of the British Foreign & Colonial Corp., has become temporary chairman of the board and will be in control of finances.

Banks have come to the relief of the company, but it is proposed to raise a larger amount later by the sale of debentures. Szarvasy will make a full statement of the company's affairs to stockholders on Feb. 11. It is understood that Lord Ashfield of the London Underground Electric Railway later will become chairman of the board.

Necessary credits have been arranged to meet all obligations pending permanent financing. Because of the financial situation it has been found impossible to further finance the Dunlop American Co. and the English company has assumed the responsibility for it, thereby safeguarding its position through the assets of the American concern.

Domestic Mail Rates Extended to 5 Countries

NEW YORK, Feb. 4—The domestic postal rate, beginning this month, will apply on all letters and post cards to Bolivia, Colombia, Honduras, Nicaragua and Peru, according to an order just issued by the Postal Department. The new rates have been put into effect as the result of negotiations commenced at the International Postal Congress held last November at Madrid, Spain. The domestic rate also applies to periodicals (one cent for each four ounces or fraction thereof). The maximum weight for periodicals and other printed matter, including commercial papers, is 8 lb. 12 oz., while the maximum volume for single volumes of printed books will be 11 lb., the maximum dimensions for this class of mail matter in the form of a roll being 40 in. in length and 6 in. in diameter. Cuba also has confirmed the new postal convention.

PERFECTION ASSETS HIGH

MILWAUKEE, Feb. 7—Schedules filed by the Perfection Engine Co. upon an involuntary petition in bankruptcy, show assets of $27,273 and liabilities of $16,306. The first meeting of creditors is called for Feb. 11.

Willys Corporation in Bankers' Control

Formation of Single Operating Company May Follow—Interests of Company Extensive

(*Continued from page* 288)

The first preferred stock provides that without the consent of at least 75 per cent of the outstanding first preferred the corporation may not:

1—Create or permit any subsidiary company to create any mortgage other than purchase money mortgage, lien or incumbrance on the property.

2—Issue any obligations maturing later than one year from the date thereof.

3—Issue any stock having priority over or on a basis with the present first preferred.

4—Authorize additional first preferred stock without the consent of 75 per cent of the holders of outstanding first preferred unless the net value of the tangible assets of the corporation including the proceeds of the preferred stock to be issued, are three times the largest aggregate amount of first preferred stock outstanding, or the net earnings for twelve consecutive months out of the preceding fourteen months are three times the dividend requirements of the first preferred outstanding and to be issued.

The first preferred has preference as to dividends over both the second preferred and common stock and in case of voluntary liquidation or upon dissolution of any capital assets, holders of the first preferred are entitled to 110 and accrued dividends. The stock also provides for a sinking fund to begin this year.

The first preferred stock has no voting power unless four quarterly dividends are in default of sinking fund payments, in either of which events it shall have the right to elect the majority of the board of directors.

While no authoritative announcement has been made covering the proposed reorganization of the Willys interests, it can be said that the program which had been virtually determined upon a few weeks ago was for the consolidation of all the Willys units in a single company patterned after the General Motors Corp. This would include the Willys-Overland Co. and the Willys Corp. with their various subsidiaries.

Overland Covers Wide Field

The Willys-Overland Co. owns the Willys Morrow Co., of Elmira; the Wilson Foundry & Machine Co., of Pontiac; the Moline Plow Co., and all branches of the plow company. The Willys-Overland Co. has plants at Toledo, Elyria, Ohio, and Elmira, N. Y.

John N. Willys personally is credited with owning control of the Republic Truck Co., of Alma, Mich.; which in turn owns all the common stock of the Torbensen Axle Co. of Cleveland. Willys and two other men control the Fisk Rubber Co., which in turn controls the Federal Rubber Co. Another company controlled by Willys and his associates is the United States Light & Heat Corp. of Niagara Falls.

If such a consolidation were effected, it would result in the formation of a gigantic corporation ranking next to General Motors in the automotive field. Promoters of the plan would be confronted with countless difficulties and an immense amount of detail which could be smoothed out only by long continued conferences. One of the chief difficulties would rest in the fact that the preferred stock in nearly all the Willys companies contains provisions similar to that carried in the first preferred in the Willys Corp.

The difficulties of the Willys Corp. are the result of conditions brought about by the period of readjustment through which the country is passing and which caused the virtual collapse of the market for its products.

Bank Attitude Constructive

The bankers interested in the corporation have assumed a constructive attitude and it is confidently believed the merchandise creditors will do nothing to embarrass the backers of the reorganization plan. They are expected to assume the constructive attitude recently displayed by the creditors of the Moline Plow Co.

The troubles of the corporation are believed to be of a purely temporary character and when the demand for their products increases, as it undoubtedly will in a short time, it is expected the burden will soon be lightened. It is considered certain that none of the interests involved will take any step which would necessitate drastic action and that some means will be found which will adequately protect all the investments already made.

Walter Creditors to Get Commission on Sales

NEW YORK, Feb. 4—Business of the Walter Sales Co., Inc., in this city will be continued under a creditors' committee, on which will serve John G. Scattergood, vice-president of the Gotham National Bank; C. W. Decker, manager of the industrial finance department of Robertson-Cole Co.; Seymour K. Fuller, attorney for the Mutual Finance Corp., and William Walter, president of the Walter Motor Truck Co. Unsecured debts of the company total $125,000 and assets possibly less than $2,000.

The committee hopes to realize enough revenue to pay the claims of creditors in one or two years by continuing the sale of Walter trucks. An agreement has been made with a well-known truck company whereby William J. Aitken will sell its trucks on commission, and will also sell the Walter truck, the commission on the latter, less expense of sales, to be distributed pro-rata to the creditors.

Reeves Sees Trade in Rallying Stages

Question of Credits Important to Farmers—Hysteria in Industry Passed Over

(*Continued from page* 291)

that the big city banks are doing their share in carrying the distributers and big dealers. Because of the heavy burden of the small town banks in carrying crops of farmers, they have not been able to do much to help the small town dealer.

"We had a long session with Governor Miller of the Federal Reserve Bank of Kansas City, and Asa E. Ramsay, his deputy governor. They insisted that reduction of automobile credit last year was vitally necessary in their territory, not because the automobile business was not essential, but because it already had big credits, and other matters were more pressing. Mr. Miller said his bank had just gotten out of debt for the first time in eighteen months and he hoped soon to be able to again rediscount automobile and some twenty other kinds of paper that had been temporarily sidetracked during the pressing need from the agricultural districts. The member bankers have continued to care for their automobile customers.

"The farm trade is certain to be poorer than usual this year. Not alone are crops, raised with high labor costs, bringing very much lower prices than expected, but many tenants have raised their crops on land rented at high prices in some cases where the crop will not bring an amount equal to the rent.

"On this three weeks' trip we found that the hysteria in the industry has passed and that the manufacturers and dealers are putting their houses in order and are preparing for a conservative, normal year with intensive sales effort as the high keynote.

Truck Dealers Discouraged

"In connection with trucks, we found the dealers somewhat discouraged with present conditions. A slowing down in business has materially decreased the demand, while the open weather has permitted the railroads to carry all the freight offered. In fact, the railroads now report 300,000 idle freight cars.

"Bankers and the far-seeing dealers know that the truck business has a fine future, which depends somewhat on how soon we have renewed business activity and how soon the program for our much-needed building operations get under way. The railroads, too, will buy trucks for short haul work, which spells brighter days for motor trucks, of which we have less than a million in use."

Reeves will attend a dealers' meeting at Syracuse Friday night, and will visit other cities as his time permits.

Goodyear to Operate Under Voting Trust

Details of Refinancing Wait Stockholders' Approval — Name Supervising Committee

NEW YORK, Feb. 9—The eagerly awaited report of the plan decided upon for the reorganization and refinancing of the Goodyear Tire & Rubber Co. was made public to-day. It provides for recapitalization and readjustment of the debt and was agreed upon only after weeks of negotiation.

The program will be submitted to the stockholders for ratification at a special meeting to be held in the next fortnight. The adjourned meeting which was to have been held Friday for discussion of the refinancing will be deferred again.

There have been persistent reports that when the plan went into effect there would be important changes in the management with the elimination of President Seiberling from active control but official confirmation is lacking. Robert T. Swaine, who is associated with Paul D. Cravath, counsel for the company, said to-day there was no certainty any changes would be made and denied emphatically that any had been decided.

The agreement provides that provision satisfactory to the merchandise creditors will be made for the future election of directors by the creation of a voting trust or by the creation of management stock vested in five persons designated by the merchandise creditors whose claims are said to aggregate $70,000,000.

Before the plan can be declared operative it must be approved by the company's stockholders in a meeting to be held shortly, and the stocks which are to go to the merchandise and contingent creditors must be exchanged for the debt by negotiation with every creditor. Steps taken denote co-operative progress, but it is recognized that it will be several weeks before the plan can be consummated. The only issuance of securities for sale to the investor contemplated is $25,000,000 of first mortgage twenty year 8 per cent sinking fund bonds, but that financing will not be undertaken until the junior situation is cleared up.

Plan Generally Approved

The plan, as agreed to, is a sort of when, as and if issued affair, although it has been assented to by the bankers, the largest creditors and the holders of a majority of the company's common stock. Holders of the existing common and preferred stock will receive like amounts of stock in the reorganized company, except that the shares will be changed to no par value for the purpose of wiping out the existing deficit and of funding 25 per cent of the company's liabilities on merchandise commitments, on which specifications and prices have been fixed. Then the company will be recapitalized by the issuance of the following additional securities: Twenty-five million dollars of first mortgage bonds, $25,000,000 of ten year 8 per cent sinking fund debentures, $35,000,000 of 8 per cent preference stock, $65,000,000 of 7 per cent preferred stock, and 900,000 shares of common stock of no par value.

The bank creditors' committee will try to effect the sale of $25,000,000 of debentures, $35,000,000 of prior preference stock and 256,000 shares of common stock to present holders of the company's stock. Cash realized by the company from that sale will be applied toward the payment of its bank debt and to provide it with new working capital.

Will Pro-rate Contracts

Regarding the pro-rating of material contracts the plan says:

"Such arrangements as the merchandise creditors' committee may approve shall be made to the end that the company shall not be required to take materials on contracts on which specifications and prices have been fixed faster than they are needed for production, provided it takes no similar materials from others than those with whom it has contracts at present, and also to the end that deliveries when taken shall be equitably prorated, the particular kind of material considered, to such existing contracts, and in the case of rubber to existing contracts and rubber now pledged to secure bank debt. The banks holding debt so secured will be asked, as part of the plan, to extend the debt pending such use of the pledged rubber."

Present commitments for future deliveries of merchandise on which specifications and prices have been fixed are:—

For rubber	$ 7,200,740
For cotton	5,664,000
For fabric	41,879,763
For other materials	215,000
Total	$54,959,503

The plan will be carried out under the supervision of a bank creditors' committee, composed of Robert C. Schaffner, Chicago; John Sherwin, Cleveland, and Ralph Van Vechten, Chicago; a merchandise creditors' committee, composed of W. E. Bruyn, New York; F. L. Jenckes, Providence; Myron C. Taylor, New York; a preferred stockholders' committee, composed of George W. Crouse, Akron; Reamy E. Field, Cincinnati; Charles A. Morris, Cleveland; A. H. Scoville, Cleveland, and J. Herndon Smith, St. Louis, and a common stockholders' committee, composed of Fred S. Borton, Cleveland; C. R. Erwin, Chicago; E. E. Mack, Canton; Russel L. Robinson, Akron, and F. A. Seiberling, Akron.

VAN SICKLEN ON PART TIME

ELGIN, ILL., Feb. 7—A report that the Stewart-Warner Corp. is negotiating for the purchase of the Van Sicklen Speedometer Corp. is denied by the latter, but it is announced that the plant, closed for some time at Elgin, Ill., has been reopened and will operate upon a five-day basis. It is also announced that the holdings formerly held by Eastern parties have been purchased by residents of Elgin. This, however, will not make any change in the policy or management.

New York Would Ban Use of Heavy Trucks

Prohibitive Taxes Outlined for Legislation on Capacities of 5-Ton and Over

ALBANY, N. Y., Feb. 8—Heavy motor trucks will be taxed off the roads under the plan of legislation being drafted here to meet the recommendations of Governor Miller's annual message. No secret is made of the intention of the legislation, the lawmakers taking the view that the use of heavy trucks imposes prohibitive upkeep costs, and that the best way to check this is to tax the heavy vehicles out of existence.

Under the proposed legislation annual fees of $500 are fixed for trucks of 5-ton carrying capacity; $600 for 6-ton; $700 for 7-ton, and $800 for 8-ton. Trucks of less than 5-ton capacity would be permitted to operate for $50 to $90 a year.

License fees for passenger cars under the new proposed rate would not exceed 10 cents per horsepower, whereas the present rate is 25 cents. The bulk of the tax would apply on car value and it is estimated would add about $2,000,000 annually to the State's revenue.

"The high tax on motor trucks is being proposed with the deliberate purpose of putting an end to the use of super-motor trucks on our roads," said Senator Lowman, chairman of the Senate committee on internal affairs. "We cannot drive them off the roads but we propose to tax them off. They tear up the roads frightfully and make not only the upkeep of the roads but the cost of construction and maintenance of bridges along the State roads prohibitive. The interests involved must be compelled by the only means at our disposal to distribute the weight of their loads and use smaller trucks."

The new motor vehicle bill will be sponsored by Senator Hewitt.

N. A. C. C. Prepared to Act

NEW YORK, Feb. 9—New York subcommittees of the National Automobile Chamber of Commerce will be prepared to take instant action when the new motor vehicle legislation is presented, said Harry Meixell, secretary of the motor conference committee. Whether the act will be as drastic as outlined is questioned by him, but he said every precaution would be taken to protect the interests of the industry.

REYNOLDS ORDERED DISSOLVED

MT. CLEMENS, MICH., Feb. 10—The Circuit Court of Macomb County has signed an order dissolving the Reynolds Motor Truck Co. and appointing Charles J. Reimold permanent receiver under a bond of $75,000. A request by a creditors' committee for the appointment of a joint receiver as their representative was denied. The creditors committee now is considering the advisability of filing an involuntary petition in bankruptcy.

Manufacturers Hold Production Rate Low

Surplus Stocks Diminish Gradually as Buying Resumes—Labor Resents Wage Cuts

DETROIT, Feb. 8—The attitude of automobile manufacturers indicating determination not to be swept off their feet by optimism engendered by the show is indicated in an almost universal decision not to increase production schedules for the time being. The tendency toward conservatism is shown plainly in figures for January with a total output of 14,615 cars in 32 factories in Detroit and Michigan and in the Overland and Willys-Knight plants in Ohio. This is far behind that of December, though a comparison would not be fair for the reason that Ford operated until Christmas Eve. The output in the same factories in January, 1920, was 180,310, which included the output of both Ford and Dodge.

While there are indications that production for February will not be increased materially, the spring demand will prompt increased schedules in March. Whether this spring business will reach anything like normal proportions is a problem, but it certainly will mean the resumption of operations in all plants with current demand determining output. It is contended by many that with the curtailed production of the last few months, the surplus stocks are rapidly being dissipated and the factories will be kept busy supplying the demand after March.

The contention is admitted generally; though the more conservative among the manufacturers regard the term "busy" as meaning that the factories will be operating full time but with greatly reduced forces and the production schedules ranging from 40 to 50 per cent of the 1920 record. Adding to prevailing unfavorable conditions are the labor troubles, which are beginning to loom large despite unemployment. While the strike now in progress is confined to the body plants, the agitation for return to high wages paid last year and antagonism toward present reduced wage scales is felt in the automobile plants. This attitude is being nurtured by idle men.

Strike Closes Fisher Plants

The strike spirit spreading through the plants of the Fisher Body Corp. following the walkout in the trimming and painting shop resulted in an order yesterday closing all that company's plants and the plant of the Anderson Electric Co., which makes bodies for Packard and other companies, is closed. The Automobile Body Co., which was closed on account of the strike, has been reopened with non-union labor. The strike in the body department at the Packard plant is regarded as responsible chiefly for the closing of that factory.

Everett Bros. plant will not be in operation for some time and consequently is not affected. Briggs Mfg. Co., which resumed operations on slightly under 50 per cent basis ten days ago, has not been affected by the strike. This company builds Ford bodies exclusively and now has about 1300 men working, though they admit operations are indefinite and believe the plant again will close unless operations start at the Ford factory soon.

No one seems even to guess what the Ford plans are, though the fact that the parts makers have been given no orders to start is regarded as significant and builders of Ford parts are a unit in expressing belief there will be no production there until after March 1. This situation was forecast at the time the plant went down Christmas Eve. The plant is practically idle. Only about 500 men are at work and they are employed solely in replenishing the parts stock.

Dodge Surplus Still Large

Dodge plans are equally mysterious. Dodge had a large surplus of cars in storage when production was stopped and although there has been some demand, especially in certain sections, the stock in the warehouses, in transit and in the hands of dealers, still is said to be large. President, F. J. Haynes said this week, no plans for reopening had been made.

Packard, which went down ten days ago, still is idle, and the 30-day maximum fixed by Vice-President Roberts as the shut down period will find the gates closed.

Reo this week went on a ten hour day full time schedule with the entire force working. Reo executives expressed confidence of continued improvement. The company delivered 1800 vehicles in January; 720 passenger cars and the balance speed wagons.

Paige reports renewed optimism among the dealers and a slight improvement in sales, though not sufficient to justify an increased production schedule and the plant will continue operation as at present—on about 25 per cent output.

There is no change at the Hudson-Essex factories. The Essex plant is still closed, but a small force is building both styles in the Hudson plant.

Cadillac was down the greater part of January and had comparatively no output, employees being used in building up the parts stock. They began on a schedule of 40 cars daily Feb. 1, but up to the present have not reached this schedule and are building about 25.

Maxwell-Chalmers plants are still idle awaiting outcome of reorganization efforts in New York.

Lincoln Sales Encouraging

Lincoln officials report encouraging outlook from the sales end, and a tendency toward improvement but the manufacturing schedules are not to be increased until such time as sales justify.

Oldsmobile is working full time building the new four and some eights but no trucks save on orders. Oldsmobile reports an encouraging outlook, but the present schedule of around 60 daily will be continued for the time being.

Briscoe is working 700 men full time

(Continued on next page)

Tractor Show Opens Wide Sales Avenue

Registration Admission System Proves Advantages—Foreign Machines Bid for Business

COLUMBUS, OHIO, Feb. 7—The six National Tractor Show, held under the auspices of the National Implement and Vehicle Association, was opened to the public in a range of eight buildings at the State Fair Grounds here this morning. The show is probably the largest that has ever been staged by any branch of the automotive industry, on the basis of floor space occupied.

By comparing the list of tractor exhibitors with a recent list of tractor makers it is evident that a very considerable number of the newer and smaller concerns are not represented. Forty-nine makes of tractors are shown, including three foreign makes, the Italian Fiat and the French Renault and Sonua, all three of which have been described and illustrated in AUTOMOTIVE INDUSTRIES.

Of the 49 makes eight are creeper tractors—the Holt, Best, Bates, J. T., Cletrac, Monarch, Hicks and Renault, and the rest wheeled types. It should be mentioned, however, that the Bates is now made in both a creeper and a wheeled type. The wheeled Bates, which is shown for the first time, is identical with the familiar "steel mule" from the front end back to the rear axle.

This year the management has broken loose from the time-honored practice of charging an admission fee, and it is hardly to be doubted that free admission will become the general rule in the future for industrial shows of products of an exclusively utilitarian character. The show management, of course, will lose quite some money from admissions, but, on the other hand, there are several important advantages to this scheme.

In the first place, the offer of a free admission will induce some prospects only as yet mildly interested in tractors, to attend, especially farmers located at moderate distances, and it is, of course, far more important to get these lukewarm prospects to the show than those already sold on tractor farming.

Buttons Identify Visitors

Then, each visitor on entering the show is compelled to register and give his business—whether he is a farmer, a dealer or an exhibitor—and after having registered he is given a button which admits him to the show, and the color of this button reveals his status.

Finally, when the show is closed on Saturday evening, the management will have an excellent all live list of tractor prospects which no doubt will be available to all members of the N. I. V. A. if not to all exhibitors, and after the different sales departments have finished their work on this list most of the prospects should have been converted into owners.

Tractor Show Opens Wide Sales Avenue

New Models All Have Four-Cylinder Engines and Enclosed Drives

(Continued from preceding page)

The participation of European tractor manufacturers in the show is worthy of note and shows that some competition from that source must be expected in the future. This is the first time that European tractors have been offered for sale here. No doubt the fact that the great majority of the farms in Italy and France are so small that a tractor cannot be used on them to advantage is compelling these manufacturers to look for outlets elsewhere, and the recent business depression abroad may also have had something to do with the move.

It is difficult to discern any general new trends in tractor design. There are a considerable number of new farm tractors at the show and all of them are of the modern type with four cylinder engines, enclosed drive and generally clean design. Following is a list of the new machines with a brief outline of their characteristics; full illustrated descriptions of the more important designs being reserved for a future issue.

The Huber Mfg. Co. exhibits the Huber Super Four which has a Midwest engine, but is otherwise very similar to the Huber Light Four. It has a 15-30 hp. rating and the two speeds are 3 and 4½ m.p.h. A dry disk clutch is used.

The J. I. Case show a new 40-72 hp. tractor designed along the same lines as their smaller machines, and their complete line has now been revised on modern lines. This is the first time, so far as the writer knows, that a giant tractor, that is, one of more than five plows capacity, has been designed on strictly modern lines with a completely enclosed drive and none but cut gears running in oil.

A larger Twin City model, a 20-35 hp., similar in design to the Twin City 12-20, is being exhibited by the Minneapolis Steel and Machinery Co. The gears on this tractor are made of chrome nickel steel and are shrunk onto wheel centers, the drive being taken on splines on the centers and ring gears. This machine weighs 8500 lb.

Aultman-Taylor Makes Change

Several important changes in their 15-30 hp. model have been made by the Aultman-Taylor Machinery Co. One is the substitution of a drop forged I section axle for the built-up front axle and another the provision of a cross spring in front. A tubular radiator is now fitted and there is a brake acting on the belt pulley.

Several changes in equipment have been made by the Samson Tractor Co. An air washer is now fitted, located on the left side of the cylinder block. Two Hyatt bearings are mounted in each front wheel, and clutch control is provided so the clutch can be locked in position when doing belt work. The fan is now made with a double bearing, driven by a wide flat belt and provided with an automatic tensioning device. An impulse starter, a radiator shield and an exhaust pipe extending below the rear axle, have been added to the equipment. A large hand hole is to be provided in the gear case hereafter.

The Holt Mfg. Co. exhibited a snow removal tractor as sold to the City of New York, and tractors for the same purpose were shown by the Cleveland Tractor Co. and the Bates Machine & Tractor Co. The Holt concern also shows a large logging tractor with completely enclosed cab.

Revere to Operate Under Receivership

LOGANSPORT, IND., Feb. 7—The Citizens Loan & Trust Co. of this city has been appointed receiver for the Revere Motor Car Corp. by the Circuit Court of Cass County in a suit filed at Hammond by C. Edwin Osborn and other stockholders. Under the order of the court, the bank will keep the company's property intact and the plant in operation for a sufficient length of time to permit the stockholders to refinance the company.

A bankruptcy suit instituted recently against the Revere corporation was dismissed in Federal Court after a special master had declared the company solvent with assets of $1,157,328 and liabilities of only $354,659.

The Revere corporation has been made defendant in damage suits aggregating $548,000, filed in the Circuit Court here by the Revere Motor Sales Corp. of Delaware. The complaints allege breach of contract, disregard of court judgment and inability or neglect to make payments on cars sold.

The breach of contract suit asks for $450,000 damages. The disregard of court judgment suit seeks $25,000. The failure to make payments suit asks for $59,000, while a fourth suit asks for payment of $14,000, alleged to have been loaned to the local concern by the plaintiff company. Efforts for an amicable settlement of the case, started two months ago, have failed.

S. A. E. TO EXTEND RESEARCHES

NEW YORK, Feb. 9—The semi-annual meeting of the Society of Automotive Engineers will be held at the West Baden Springs Hotel at West Baden, Ind., May 24-28. West Baden was selected after a careful canvass of various places by the meetings committee.

Research work under the direction of a committee will be one of the major activities of the S. A. E. and an appropriation of $30,000 for this work was made by the council at its meeting in Chicago last week. This work is expected to become as important an activity of the S. A. E. as standardization has been and still is.

Manufacturers Hold Production Rate Low

Most Companies Get Good Reports of Show Activities from Distributors

(Continued from preceding page)

which is about one-third their regular force. Officials bring good reports and say dealers are confident of steady upward trend. The company was in production in January and will not increase their output during February but will start on a schedule of 30 daily March 1 and expect to increase this until a maximum of 75 daily is reached.

Studebaker, which opened Jan. 17, built 800 "big sixes" in Detroit. Their schedule was increased to 525 cars weekly Feb. 1.

Oakland is operating on a basis of 50 daily and striving to reach 50 per cent of normal, but officials do not expect to reach that point for 60 days. Good reports received from dealers at the show and a survey of the situation reveal less cars on hand than at the same time last year. It is reported that more Oaklands were sold during the last 90 days than were manufactured.

Buick built about 200 daily during January, and the same schedule will be maintained through February, despite the good show business and the optimistic views of dealers. March production schedules depend entirely on demand during February. The factory is working full time but with short force.

There was no production at the Willys-Overland or Willys-Knight plants during January, but they hope to clean up their surplus cars by March and resume production.

Dort this week began production of the new models and officials say they have orders ahead for 60 days. Vice-president Averill says the great interest manifested during the show indicates renewed buying, but thinks consumers will be more conservative and careful and does not look for a buying epidemic.

Saxon did not produce in January but began this week on a schedule of five daily.

The Jackson plant is working full time with about 25 per cent of its force and limiting production to actual sales requirements.

Hupp Employing 30 Per Cent

Hupp is employing about 30 per cent of its normal force and building about 20 cars a day. Hupp executives report the outlook good and President C. D. Hastings is enthusiastic over the shows.

President Sarver of Scripps-Booth said last week was the best the company has had in a long time from a sales standpoint. This applied to the Chicago show and the entire country. The company is operating with a short force and the schedule of about 10 a day will be maintained until the demand justifies greater production.

Reimported Trucks Sell at Low Price

Reconditioned Vehicles Built for French Army Sell Far Below List

NEW YORK, Feb. 8—Sixty-six trucks including Packards, Macks, Pierce-Arrows, Whites and Rikers, originally bought by the French Government and shipped to France and recently returned to this country, were sold at public auction at the L. & F. garage in Brooklyn here to-day by Samuel T. Freeman & Co., Philadelphia auctioneers. All of the trucks were fitted with standard Army types of bodies, and had seen some service, although some few had been driven less than 500 miles, according to the odometer readings and the appearance of the tires. The trucks had been on public exhibition out in the open for three days preceding the sale and were driven in singly for sale.

The consignment consisted of ten 2-ton Whites, ten 2-ton Packards and five 3-tonners, sixteen 4-ton Rikers, five 5-ton Pierce-Arrows and five 2-tonners, and fifteen 5½-ton Macks, all with cabs.

All of the trucks were bought "as is." Two of the 2-ton Whites, all of which were of 1918 models, were bought in at $1,300 and $1,325, respectively, by individual buyers with the remaining eight apparently bought in by an insider at $900 each. The 1918 list price of these trucks, without bodies, was $3,300.

The 2-ton Packards, some of which were equipped with generators for electric lighting, which listed at $3,200 in the chassis, were sold for a total of $13,200, or at an average of $1,320. The lowest selling bid was $1,225 and the highest $1,400. All of these Packards were bought by individual users whose business include shoes, chemical works, general trucking, iron dealer, farmer, builder, granite dealer, butcher and dye business. The five 3-ton Packards, which originally listed at $3,900, went for $10,850, or an average of $2,170. The lowest selling bid was $2,125, highest $2,275.

The first two of the 4-ton Riker trucks, which originally listed at $4,050, went for $2,050 and $1,150 respectively. The balance sold for $850 each.

Three of the 5-ton Pierce-Arrows, which listed at $5,000 in the chassis, went respectively for $2,225, $2,250 and $2,100. Two others went for $1,700 each. The first two of the five 2-ton Pierce-Arrows, originally listed at $3,300, went for $1,400 and $1,325 respectively, and the remaining three at $1,200 each.

The first of the 5½-ton Macks, which listed at $4,750, chassis, went for $2,450.

WILLIAM D. TREMAIN DIES

FORT DODGE, Feb. 4—William D. Tremain, 64, pioneer automobile dealer of Ford Dodge, died Feb. 1 following a serious illness. He was born in Strawberry Point, Iowa, and engaged in business in Fort Dodge in 1882. The firm of Tremain & Rankin, in which he was a partner with his brother-in-law, George F. Rankin, entered the automobile business in 1907, being the 43rd dealer in the State. He is survived by his widow and three children, George W. Tremain, Mrs. William Whalen and Mrs. Harold Sitting, all of Fort Dodge; a sister, Mrs. W. W. Stearns, Humboldt, Iowa, and a brother, H. J. Tremain, Minneapolis.

Bates Tractor Reduced to Price Before War

JOLIET, ILL., Feb. 5—Bates Machine & Tractor Co. has reduced its prices on tractors to pre-war levels. In a statement by Harry H. Bates, sales manager, the action was said to have been taken in the belief that new steel prices will justify the company in making a sacrifice of its present high-priced stock of materials.

In addition, he said, the demand for Bates tractors has grown to such an extent that increased production this year to meet new orders will result in a large cut in production costs. There is no good reason, he said, why a farmer buying a tractor for his spring work should not be able to do so as advantageously as the man buying for his fall work.

Orders for the present year are in greater volume than last year, he said, partly due to the enlarged dealer organization of the company. The principal reason for the increase, however, he declares, is the increased belief among farmers that tractor use means larger crops and a larger margin of profit.

Implement Men Deny Price-Fixing Charge

PHILADELPHIA, Feb. 4—Recent charges of price fixing, made against farm vehicle and implement retailers by the Federal Trade Commission, were vigorously denied by delegates to the Eastern Retail Implement & Vehicle Dealers Association at its ninth annual convention, in the Adelphia Hotel, this week. The convention has delegates from Pennsylvania, New Jersey, Delaware and Maryland. Grant White of this city presided.

Franklin Briggs, Woodbourne, Pa., who is the organization secretary, declared that the report of the Federal Trade Commission, charging the members of the association with a mutual agreement on prices and the barring of other merchants from entering the trade, by means of a boycott, is false.

JORDAN TO INCREASE OUTPUT

CLEVELAND, Feb. 9—Production at the plant of the Jordan Motor Co. will be increased 50 per cent on March 1, according to an announcement made at the annual meeting of stockholders of the company this week. The company expects to gradually increase production until it reaches normal. The directors re-elected were E. S. Jordan, T. E. Borton, Otto Miller, C. L. Bradley, W. B. Rily, R. S. Beggs and Paul Zens.

METAL MARKETS

REPORTS of scattered buying of modest tonnages by automotive interests are accompanied by rumors of price cutting. Youngstown district sheet mills are said to have booked orders for sundry lots of highly finished automobile sheets at 6.50c, quantities placed ranging from 50 to 250 tons. It is impossible to verify a statement that 5000 tons of black sheets have been booked by one of the rolling mills at $3 a ton below the prevailing quotations. So much is certain, however, that values are more flexible than they have been in some time and that producers are ready to discuss price, whenever representative tonnages are involved. One or two automotive foundries in Detroit have sent out market feelers and are expected to place orders for modest tonnages of pig iron in the next few days. In some of the Middle West automotive foundries, the opportunity that presents itself at this time for the weeding out of industrial slackers is being taken advantage of and furnishes another reason for slowness in pig iron buying. There is, however, a general feeling in the iron and steel markets that activity in the automotive industries is about to be presaged by a gradually increasing quota of buying for second quarter deliveries. In this impression producers are strengthened by the steadily growing number of specifications and shipping instructions that have been furnished in the last few days for tonnages, delivery of which had been temporarily "suspended" by the automotive buyers last Fall. An interesting development in connection with the opposition to the proposed increase of the tariff on imported aluminum to 7c a pound is the fact that one of the importing and brokerage houses has submitted to the Ways and Means Committee of the House of Representatives a cablegram from the largest aluminum producers in Norway, stating that, in their opinion, "if the tariff on aluminum is increased in this country, Norway will no doubt retaliate by increasing the import duty on automobiles."

Pig Iron.—While the nominal quotation for foundry pig is $30, foundry base, further recessions are generally anticipated. There are now in progress negotiations between the coke interests and the pig iron producers with a view to developing prices for pig iron that will induce buying on a more liberal scale.

Steel.—Strip steel producers report somewhat better inquiry from the automotive industries and, while so far only a very small amount of fresh business for the cold-rolled variety has been booked, the outlook is regarded as far more propitious. The Trumbull Steel Co., Warren, Ohio, is reported to have begun shipments on a large tonnage of sheets which were ordered suspended about two months ago by a leading Detroit passenger car interest.

Aluminum.—Relative firmness in the "outside" market which rules at 25c for virgin ingots, 98 to 99 per cent pure, is not due to a better demand but rather to anticipation on the part of holders and importers that not only will there be an early resumption of buying, but that possibility of an increased duty offers a chance for increased profits on what stock is in hand at the time such augmented duties might be put into effect.

Copper.—The financing plans of some of the large copper interests who contemplate the issuing of debenture bonds with their accumulations of "red metal" as the security, are interpreted by many domestic consumers as an additional sign of intensive weakness

FINANCIAL NOTES

Rolls-Royce of America is now on production of about one car daily. Net earnings of about $20,000 accrued to the American company during 1920 from sale of British-made chassis. Orders for 75 chassis are on the books of the American company, the price being $11,500, on each of which a profit of about $2,000 will be made. The only part brought here from England will be a brake member, made of material impossible to obtain in this country.

Firestone Tire & Rubber Co. showed an increase of $10,304,338 in its inventory of Jan. 1, 1921, over the $26,969,535 inventory of Jan. 1, 1920. Materials on hand, in transit and in process Jan. 1, 1921, were valued at $21,168,140, compared with $11,217,872 on Jan. 1, 1920. Finished goods on Jan. 1, 1921, were valued at $16,105,733, compared with $15,751,662 the year previous.

Gardner Motor Co., Inc., in a statement as of Dec. 31 reports resources of $2,348,554 included, in which is merchandise valued at $1,510,230 and cash of $290,759. A profit and loss deficit of $1,044 is shown. The company has no current liabilities and no borrowed money. The company will continue operations along conservative lines.

Detroit Machine Tool Co. has increased its capital from $150,000 to $300,000, to permit of plant expansion in order to take care of production of ten automotive parts, for which a special department has been equipped.

Mullins Body Co., in a financial statement issued Dec. 31, reports net sales of $3,711,420 and a net profit of $701,290. Assets increased from $2,191,196 on Oct. 31, 1919, to $4,500,056 on Dec. 31, 1920.

Harley-Davidson Motor Co., in a balance sheet as of Oct. 1, 1920, shows current assets of $1,823,982; current liabilities, $1,147,964; P. & L. surplus, $5,174,850; total assets and liabilities, $8,728,187.

North Baltimore Tractor & Machine Co. of North Baltimore, Ohio, has declared a dividend of 10 per cent and has increased its capital from $50,000 to $100,000.

Gallon Metallic Vault Co., which owns and controls the Ditweiler Mfg. Co., has increased its capitalization from $400,000 to $1,000,000.

Cotta Creditors Name Trustee for Company

ROCKFORD, ILL., Feb. 8—The Rockford Trust & Savings Co. has been selected as trustee for the bankrupt Cotta Transmission Co. Two groups of creditors voted upon the question of trustee, the minority favoring the Central Trust Co. of Chicago. It was shown that ninety-four creditors, representing $349,263, supported the Rockford Trust company, while eight-nine creditors, representing $337,403, favored the Chicago company.

At the hearing of the officers, President T. D. Reber, Vice-President E. P. Reber, and A. D. Scoville, the secretary-treasurer of the Cotta company, testified concerning the financial condition of the company. Chicago attorneys endeavored to establish proof that the officers had exerted their influence upon creditors to secure their support of the Rockford trustee. Rockford creditors naturally preferred a home concern to one from abroad. Evidence brought out by the examination of the officers into the cause for the failure showed the prime factors:

First, The change of production from a three-speed transmission to a four-speed, to meet the requirements of pneumatic tired and faster moving trucks.

Second, Firms holding contracts placed by the Rockford company for jigs, tools, and special fixtures and forgings, stampings and other material required, were from one month to one year behind in keeping their promises to deliver the necessary material for production .

Third, General slowing up of business in the entire automotive field in the early spring of 1920, with the result that many orders were canceled and others held up indefinitely.

Harrison Takes Control of Abrasive Corporation

BOSTON, Feb.7—Nathan C. Harrison, who has been president of the International Abrasive Corp., has taken over control of the company and an entirely new board of directors has been elected. The corporation now owns the Harrison Supply Co. of Boston, the National Abrasive Co. of Amesbury, Mass., and Niagara Falls, Ont.; the Superior Corundum Wheel Co. of Waltham, Mass., and the Dominion Abrasive Wheel Co. of Mimico, Ont. The offices have been consolidated here.

Harrison is president and general manager of the company and Fred M. Lamson, a vice-president of the Old Colony Trust Co. of Boston, is secretary and treasurer. The directors include B. A. Brennan, president of the Fidelity Securities Corp. of Baltimore; Lawrence Chamberlain of New York, banker; Edward S. Foster, treasurer of the Carr Fastener Co. of Cambridge, Mass.; Charles G. Schirmer of Boston, banker; Frank D. White, head of the Lincoln Oil works, Rutland, Vt., and A. J. Sunstein of Pittsburgh.

RECEIVER NAMED FOR WIZARD

CHARLOTTE, N. C., Feb. 7—C. J. Bragg has been appointed receiver for the Wizard Automobile Co., Inc., by Judge Harding in the Superior Court here. The advertising of the company was condemned a short time ago by the national vigilance committee of the Associated Advertising Clubs of the World, which declared that the Wizard company had claimed enormous dividends before it had built a single car.

DEFIANCE ELECTS OFFICERS

DEFIANCE, OHIO, Feb. 7—At the annual meeting of the Defiance Motor Truck Co. the following were elected as officers and directors: C. H. Kettenring, president; J. C. Ayers, vice-president and general manager; Charles Behringer, vice-president and works manager; H. R. Morse, secretary, and J. F. Robertson, treasurer. Frank W. Warrington, general sales manager, was also elected a member of the board.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Feb. 10—January failures were larger than for any month since January, 1916. The number of commercial failures at 1.895 showed an increase of 370 over the failures for December. The liabilities involved, however, at $52,136,631 compare with the record total of $58,871,539 of December. In other words, while the number of failures increased over 24 per cent, the total liabilities decreased nearly 11½ per cent. This would seem to indicate that the smaller firms are experiencing greater difficulties in readjusting themselves to the new conditions.

Wholesale prices in January, as indicated by Dun's compilation, declined 6.4 per cent, as against a decline of 6.2 per cent in December.

The local loan market last week became very firm, especially in the call market where call money reached 8 per cent last Monday and 9 per cent on Wednesday. The range for the week was 7 per cent to 9 per cent, as against a flat 7 per cent the week before. The time money market was very quiet, but with nominal quotations slightly higher. A rate of 7 per cent was quoted for sixty to ninety days' and four months' paper, and 6¾ per cent for five and six months' paper. The week before, the uniform rate of 6½ per cent was quoted for all maturities.

The increased number of capital issues and withdrawals of funds from this center by the Government and interior districts are said to have been partially responsible for the tightening of the market. Anticipation of further Government and corporation bond issues is probably also an influencing factor. The Federal Reserve Bank announced last week that henceforth it will charge 6 per cent on notes discounted and secured by United States Treasury certificates of indebtedness.

The excess reserves over legal requirements of the New York Associated Banks increased $6,221,920 last week, while loans increased $3,085,000, and net demand deposits declined $868,000.

The week-end statement of the New York Federal Reserve Bank revealed a condition which was more or less expected in view of the tight money market. While gold reserves increased $4,220,000 and total reserves $5,414,000, total earning assets also increased $17,390,000. Total earning assets at $1,015,430,799 were again over the $1,000,000,000 mark. Net deposits increased $13,737,000. Contrary to the general trend, Federal Reserve notes in this district increased $8,746,000, marking the first increase since Christmas week. Consequently the reserve position of the bank was less favorable than it was a week ago.

The reserve position of the Federal Reserve banks as a whole again showed improvement.

MEN OF THE INDUSTRY

C. O. Miniger, vice-president of the Willys Corporation and general manager of the Auto-Lite division at Toledo, has been named to succeed J. Allan Smith as president of the United States Light & Heat Corp. Smith resigned to head a company which will manufacture the Nera car, a light-weight commercial vehicle designed by Carl Neracher. Miniger was one of the incorporators of the Electric Auto-Lite Co., and has been closely identified with the manufacture and sale of electric devices for motor cars for many years.

F. H. Ayers has been appointed director of sales of the Fisk Rubber Co. He has been sales manager for the past four years and has completed seventeen years of service with the company. William Wield has been promoted to the position of sales manager, and C. H. Gage and L. N. Southmayd have been appointed assistant sales managers. K. S. Chamberlain has been appointed manager of export sales.

D. H. Kelly has been elected president and assistant general manager of the United States Light & Heat Corp. to succeed C. L. Lane, resigned. Kelly for the past eight years was secretary of the Toledo Scale Co. and for the past two years has held the office also of assistant sales manager of the Willys light division of the Electric Auto-Lite Corp.

Frank J. Flynn has been appointed service manager for the Connecticut Telephone & Electric Co. He has been for several years with the Connecticut company in the field, both among service stations and jobbers. I. L. Doolittle, who has been service manager for the past two years, joins the sales division of the company.

Albert A. Franklin has become a member of the automotive department of the Byron G. Moon Co., Troy, N. Y. He was for two years advertising manager of the Haynes Automobile Co., and later acted as assistant advertising manager of the Waverly Company.

H. D. Bennett, assistant cashier of the Capital National Bank, Lansing, Mich., will leave that institution March 1 to become secretary-treasurer of the Garlock Sales Co. Bennett has been an official of the sales company for some time and has been nominal secretary-treasurer.

S. B. DeReatchi, export manager of the Miller Rubber Co., has resigned to accept a similar position with the Quaker Rubber Co. DeReatchi formerly was a colonel in the Mexican army under Carranza and also served as attache of the Mexican embassy in New York.

L. K. Cooper, for some time assistant to the general manager of sales of the Chevrolet Motor Co., New York, has been appointed sales manager of the Chevrolet Motor Co., of Illinois, with offices in Chicago. H. H. Mundy, formerly Chicago sales manager, has been transferred to Kansas City.

C. C. Smith, who has been assistant secretary and manager of the American Petroleum Industries for the past two years, has resigned and on Feb. 15 will take charge of the New York territory for the James Berry's Sons Co., oil jobbers.

L. M. Klinedinst has been appointed assistant sales manager of the Timken Roller Bearing Co. He has been connected with the company for sixteen years, serving last as manager of the tractor and farm implement division of the sales department.

Arthur P. Hawes has joined the organization of F. E. Wing, Marmon distributer in New England, as sales manager. Hawes was at one time manager of the Locomobile in Boston and later became manager of the Philadelphia branch of the same company.

R. G. Schulze, who has been head of the export department of S. F. Bowser & Co., Inc., manufacturers of gasoline pumps and tanks, has been appointed chief executive of the concern in England with entire supervision of the company's affairs in Europe.

E. A. White has been elected president of the American Society of Agricultural Engineers. He is the holder of a degree of doctor of agricultural engineering bestowed by Cornell University.

R. I. Pierce has resigned as production manager for the Gramm-Bernstein Motor Truck Co. to handle sales and supervise installations in the outlying sections for the Holland Furnace Co., Lima, Ohio, branch.

Thomas Calloway, assistant aeronautical manager of the Goodyear Tire & Rubber Co., has resigned to enter business in Chicago. Calloway was in charge of the Goodyear exhibit at the California aeronautical exposition.

C. A. Erickson has resigned as general manager of the Standard Radiator Co., Springville, N. Y., to enter the sheet metal automotive parts business. Erickson also was formerly chief engineer of Scripps-Booth.

A. R. Sadler, service manager of the Goodyear Tyre & Rubber Co. of Great Britain, Ltd., has sailed for London after a series of conferences with officials of the main Goodyear offices in Akron.

Newton Noble, for seventeen years head of the development department of the B. F. Goodrich Co., has resigned. Noble has made no announcement of his contemplated future connections.

S. T. Thompson has succeeded J. K. Cravens as director of sales of the Duplex Engine Governor Co., Inc., Brooklyn, N. Y. George L. Ritter will be assistant director of sales.

E. Hunn, Jr., assistant to President E. H. Hare of Hares Motors, has been made general manager of the Enterprise Motor Corp., New York distributor of Kelly-Springfield trucks.

John P. Franck has been appointed sales manager of the Ditweiler Mfg. Co., Galion, Ohio. He will also continue his connection with the Guide Motor Lamp Co.

T. W. Van Sickle has resigned from the sales force of the New Departure Mfg. Co., effective March 1. He has not announced future plans.

L. J. Ollier, export manager of the Studebaker Corp., has sailed for Europe on a business trip and will return about May 1.

MAURICE J. MOORE DIES

INDIANAPOLIS, Feb. 7—Maurice J. Moore, secretary-treasurer of the LaFayette Motors Co., died at St. Vincent's Hospital, Feb. 1, following an operation on a dislocated knee with which Mr. Moore had been troubled ever since his college days, when he injured it in a football game. He had lived in Indianapolis since coming here with the LaFayette Motors Co. in August, 1919. He was also president of the LaFayette Building Co., formed for providing homes for workmen of the motors company near the plant.

Mr. Moore formerly was with the Chevrolet Automobile Co., at Detroit and Flint, Mich. During the war he served as a major in the Motor Transport Corps.

INDUSTRIAL NOTES

Transport Truck Co. is completing a new storage dock that will add materially to the facilities for handling the company's business. The dock is 90 by 240 feet and has a total floor space of 2600 feet. The addition permits a complete switch track system operated on either side of the building and facilities for export crating are included.

Wright Carriage Body Co., Moline, Ill., has been changed to that of the Moline Body Corp. Originally opened for the manufacture of carriage bodies, the company has dropped this line and is now manufacturing bodies for motor vehicles.

Baker-Galva Tractor Co., organized last fall and which planned to erect a manufacturing plant in Galva, Ill., has abandoned the proposition and will go to Decatur, Ill., instead. Adequate financing is promised in Decatur.

Austin Machinery Corp. of Louisiana has been incorporated with a capital of $100,000 preferred stock and $200,000 common, to distribute in four southern states the products of the Austin Machinery Corp.

Reed-Prentice Co. plant, Worcester, Mass., will house the executive departments of that company, the Becker Milling Machine Co., and the Whitcomb-Blaisdell Machine Tool Co., after Feb. 21.

Northern Trailer Co., a subsidiary of the Bangor Motor Co., has begun manufacture of trailers, sleds, snow plows, etc., at South Orrington, Me.

Master Tire & Rubber Co. has elected as directors, George H. Kramer, George Marshall, Jr., and Edward Luthman.

American Auto Accessories Co., Denver, has changed its name to the Sewell Mfg. Co.

Liquidation Sought of Interlocking Tire

AKRON, Feb. 8—Following several conferences, creditors and stockholders of the Interlocking Cord Tire Co. have practically abandoned all attempts at reorganization of the company and have again petitioned the Common Pleas Court to name a permanent receiver so that liquidation may proceed. The reorganization plan was the outgrowth of offers made by President Walter Kline, Secretary C. E. Foust, Sales Manager J. W. Rinear, and Treasurer L. W. Rinear, to resign. All four are under criminal indictment for alleged violation of the Ohio Blue Sky law.

According to Elihu Harpham, temporary receiver, the company's direct liabilities are $150,000 and contingent liabilities will range from $50,000 to $150,000, with known assets not to exceed $125,000.

CASE PLOW ON 3-DAY WEEK

RACINE, WIS., Feb. 7—To aid workers to overcome the effects of a period of unemployment, the J. I. Case Plow Works Co., on Feb. 1 instituted a schedule of operation of three days per week. Preference is being given to married employes and single men supporting others. Several other large industries in Racine are following a similar plan. The recent Federal survey of industrial conditions gave Racine a total of 7000 out of work.

Calendar

SHOWS

Feb. 12-19—Hartford, Conn., Annual Automobile Show, Hartford Automobile Dealers Ass'n, Armory, Arthur Fifoot, Mgr.

Feb. 12-19—Kansas City. Annual Automobile Show, Kansas City Motor Car Dealers' Ass'n.

Feb. 14-19—Winnipeg, Western Canada Automotive Equipment Show.

Feb. 18-28—San Bernardino, Cal., National Orange Show, Fred M. Renfro, Mgr.

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, Secy'.

Feb. 21-26—Salt Lake City, Annual Automobile Show. Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatzky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 3-9—Denver, Annual Automobile Show, Auditorium.

April 4-9—Seattle, Annual Automobile Show. Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April—Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland. Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

October—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

CONVENTIONS

May 4-7 — Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

Champion Is Elected to Head Old Timers

CHICAGO, Feb. 4.—The Old Timers' Club, which was a more or less informal and spontaneous organization originated a year ago in the office of the Standard Parts Co., in Cleveland, assumed definite form this week at the first annual dinner of the organization at the Congress Hotel.

After a year of button-wearing and rapid growth officers were elected, and the organization formalities are to be completed by a committee. Albert Champion of the Champion Ignition Co., Flint, was chosen president. He came to America twenty-one years ago from France, a professional bicycle rider, and has been a part of America's automobile industry ever since.

Clifford Ireland, member of Congress, was toastmaster. Addresses were made by David B. Beecroft, directing editor of the Class Journal papers; Forrest J. Alvin of the United States Motor Truck Co., Cincinnati, and Samuel E. Hibben, attorney, Chicago. The officers follow:

President—Albert Champion, Champion Ignition Co. Vice-Presidents—Passenger car section, Howard Marmon, Nordyke & Marmon Co.; motor truck section, Martin L. Pulcher, Federal Motor Truck Co.; parts and accessories section, John Younger, Standard Parts Co.; jobbers' section, Gregory Flynn, Edward A. Cassidy Co., New York; distributors' section, W. L. Hughson, San Francisco; dealers' section, Thomas J. Hay, Chicago; newspaper section, Walter Bermingham, *Chicago Evening Post;* automobile publication section, C. G. Sinsabaugh, *Motor Life;* contest section, Richard Kennerdell, chairman, contest board, A. A. A.; organizations section, Alfred Reeves, general manager, National Automobile Chamber of Commerce; advertising section, Lloyd R. Maxwell, Erwin Wasey & Co., Chicago. Secretary—F. Ed. Spooner, Detroit. Treasurer—H. S. Firestone, Firestone Tire & Rubber Co.

McCord Creditors to Guard Interests

DETROIT, Feb. 9—Creditors of the McCord Mfg. Co. will meet Friday to select an advisory committee to take charge of the company's affairs to guard against any action which might prove detrimental to the interests of both the company and creditors.

A letter announcing the meeting was sent out over the signatures of ten banking creditors headed by Frank G. Smith, vice-president of the First and Old National Bank, Detroit. The concern lists total assets as of Dec. 31 of $11,700,000 to pay quick liabilities of about $500,000 accounts payable and $1,900,000 long term bonds. They are confronted with large inventories and accounts receivable, which they are unable to convert quickly into liquid assets. The letter says the inventories are reduced to prices which would be salable when the demand revives, but the customers' contracts are on a basis of higher prices.

PEUGEOT TO BUILD HERE

NEW YORK, Feb. 7—The Peugeot Automobile Co. of France will form an American company to be known as the Peugeot Company of America, with an authorized capital stock of $3,000,000 8 per cent cumulative preferred, and 50,000 shares of common stock of no par value. The company will manufacture Peugeot cars at a plant to be located in New England. Of the stock, $1,500,000 preferred and 25,000 common shares will be issued at once.

Mexican Development Opens Way to Tractors

NEW ORLEANS, Feb. 7—The Department of Fomento (development) of the Federal Government of Mexico, which has been supplying agricultural implements and seeds at cost to farmers of small tracts throughout that country, also is now prepared to handle tractors, motor trucks and other automotive farm and road-building machinery, likewise at cost, for other and larger farmers who may order it through that department, according to Arturo M. Elias, the new consul-general of Mexico, who arrived at his headquarters in New Orleans, Feb. 1.

"I would suggest," said Consul Elias, "that tractor and truck manufacturers wishing to get a foothold in Mexico, communicate with the Department of Fomento as to the placing of their automotive machinery. Such letters may be made in English, and should be addressed to the Secretary of the Department of Fomento, who is a minister in the President's cabinet. The Mexican government owns and operates the Compania Naviera Mexicana, which now has nine steamers in operation between New Orleans and Mexico, and the agricultural machinery will be handled from shipside, at New Orleans, the government taking it from the hands of the manufacturer at that point. More than 20,000 persons have returned to agricultural pursuits since the new government of Mexico came in, and the need for these implements is great."

RANGER TRUCK ADVANCED

HOUSTON, TEX., Feb. 7—Price of the Ranger truck, model TK-22, has been increased from $2575 to $2875 by the Southern Motor Mfg. Assn., Ltd., of this city.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV | NEW YORK—THURSDAY, FEBRUARY 17, 1921 | NO. 7

Revised Registration Figures Show Trend of Sales

Analysis of the 8,932,458 registrations shows sales possibilities of the Southern States just beginning to be developed. Agricultural States have largest number of cars per capita, but still form large market.

THE annual registration article, published in AUTOMOTIVE INDUSTRIES of Jan. 13, stated that there were 8,887,572 cars and trucks registered in the United States, and announced at that time, a later revision of these figures. This article presents these revisions, made after careful checking with the final records of the various secretaries of state. A discussion of the various conclusions which may be drawn from the statistics was also promised in the Jan. 13 number, and is included in the present article.

The revised figures given in this article show accurately the number of cars registered in the various states. Few changes are to be noted in the revised figures, except in the case of Florida, the figures for which were not available in time for the previous publication and had to be estimated.

The revised total registrations is still closer, however, to the nine million mark, 8,932,458 cars and trucks being registered in the United States during 1920. The total in each case comprises the registrations as of Dec. 31, 1920. This is an actual increase of 1,335,955, or 15.65 per cent over 1919. There is one car for every 11.84 persons.

The total fees for the year ran well over $98,000,000, thus making available a large sum of money for road maintenance and improvement. This is nearly $30,000,000 more than was paid into the various state treasuries during the previous year in license fees. A reliable computation states that 92 per cent of these fees are devoted to highway work and 8 per cent to administrative work.

For purposes of sales analysis, the country logically divides into four sections, industrial rather than sectional, except in the case of the Southern States. This division is as follows:

1—Agricultural States.
2—Manufacturing States.
3—Mining States.
4—Southern States.

Viewing the registration from this standpoint permits an analysis of the automotive market as well as of the trend of sales during recent years.

The States included in these sections are as follows:

1—Manufacturing States:
Massachusetts, New York, Pennsylvania, Michigan, Indiana, Delaware, Connecticut, Rhode Island, New Jersey and Wisconsin.

2—Agricultural States:
Arkansas, North Dakota, South Dakota, Kansas, Minnesota, Nebraska, Oregon, Oklahoma, Texas, Washington and Iowa.

3—Mining States:
Wyoming, Nevada, Utah, Montana, Colorado, Arizona, Idaho and New Mexico.

4—Southern States:
Florida, Georgia, Virginia, North Carolina, South Carolina, Kentucky, Tennessee, Louisiana, Mississippi, Alabama, West Virginia.

As would be expected the manufacturing states show the largest total registration. The totals for the sections for 1920 are:

Manufacturing States	3,607,750
Agricultural States	2,468,093
Mining States	374,106
Southern States	1,084,050

This shows that about half of the total number of cars and trucks in use are concentrated in the big manufacturing states. This proportion corresponds in a general way with the proportion of population concentrated in these sections. The population of the manufacturing group according to the 1920 census figures is 43,308,991, while the total for the three other groups is 49,111,684.

Relative Density of Automobiles

A comparison of the relative density of automobiles in the various sections brings out more definite trends. The chart shown in Fig. 1 presents the course of registrations per capita since 1912. The curve shows graphically the trend of sales resistance during the last ten years.

In 1912, it will be noted, the manufacturing states were far ahead in the proportion of cars registered. At that time the manufacturing states had one car for every 80 persons, while the agricultural states lagged far behind with one car for every 140 persons. This state of affairs was natural since selling effort was much easier in cities than in the rural districts. Even though there was a potential market for cars on the farms at that time, it was not cultivated since large sales were to be made with less effort in the cities.

The same thing applies to sales in the mining states at that period, while the Southern States were behind probably for much the same reason in 1912. In this later case, however, the lack of good roads should probably be added as a reason, since the South contained sufficient urban areas to present in many cases a concerted group of potential buyers for selling effort.

Following the curve through succeeding years, the increased sales resistance in the large cities and more congested areas of the manufacturing states becomes apparent, together with the consequent development of the farm market. The years 1912 to 1915 each recorded an enormous percentage of gain in the agricultural states, while the number of persons per car did not seek a low level as rapidly in the better supplied manufacturing areas.

*Registration year ends July 1. Figures for Jan. 1 †Estimated. ‡Figures as of December 1.

This action continued until 1917, when the agricultural states finally showed fewer persons per car than the manufacturing states, while the mining states passed the manufacturing during the same period and even slipped down below the agricultural states by a slight margin.

This relation has been preserved to a large extent in the 1920 figures, which show the number of persons per car in these sections as follows:

Agricultural States	8.10
Mining States	8.90
Manufacturing States	12.00
Southern States	20.08

Market in Southern States

During this entire period the Southern states have consistently lagged behind. This fact, together with the changes noted in the three other curves, would indicate that intensive sales effort has not yet been directed to the states comprised in this group. But as the number of persons per car becomes lower in the three other groups it is apparent that sales resistance will increase accordingly.

And at a time when sales resistance is particularly acute for a variety of reasons, unconnected with this factor, it would seem necessary in the near future seriously to study the possibility of intensively cultivating that market which, in one phase at least, offers less sales resistance.

The slow progress in the Southern states, of course, can be attributed to several factors:

1—Roads in this section of the country are not nearly as good as in the States comprised in the other groups.

2—A large negro population, most of which does not comprise a market for automobiles, makes the figures for this group of States somewhat higher than it would be if only potential automobile buyers were included.

3—Lack of educational facilities and popular education as compared with the North. Automobile sales increase as the general level of education rises.

To make a detailed analysis of the Southern market for any particular make of car would involve the consideration of a number of important factors besides the mere registration figures. The number of cars registered, however, form a sound indication of certain trends and can well be used as a foundation upon which to base a more detailed analysis of this large potential market.

In this connection, it is well to note that the development of a good used car market among certain parts of the population of the South may form the basis of a future market for new cars. One dealer tried this in a certain section, and found the colored population to be large buyers of used cars. This particular dealer was able to absorb the used cars of a particular make from several territories in his vicinity.

With $11,099,617 collected in motor fees during the last year, nearly all of which should be available for road maintenance, the roads in this Southern group should be well kept up. That is one of the greatest barriers to automobile and truck sales is being rapidly broken down, thus rendering this section the next logical area for intensive sales cultivation. The latest federal figures show that $92,500,000 will be spent on roads during 1921 alone in this group of states, about 15 per cent of the entire amount to be spent in 1921 throughout the United States.

Ohio Shows Large Gain

The gain in registration showed by Ohio is particularly noteworthy, since this state was near the top in total registrations even in 1919. For such a state to lead all the rest in actual gain is unusual at this stage of the business. New York, for instance, which leads in total registrations both in 1919 and 1920, is in second place in actual gain, while Pennsylvania, which has the third largest registration total, is in sixth place as regards actual gain.

In other words, Ohio is making more rapid strides than any of its close competitors in the race for first place. Of the states that are high up in the population scale, Ohio has the greatest number of cars per capita. Taking only those states whose population is four million or more, the number of persons per car is as follows:

Ohio	9.38
Texas	10.91
Illinois	11.41
Pennsylvania	15.45
New York	15.52

Thus it appears that Ohio, although a thickly populated industrial state, has already absorbed many more cars per person than any other similar state. Only two other manufacturing states surpass it in this respect, Michigan and Wisconsin, neither of which has nearly as large a population.

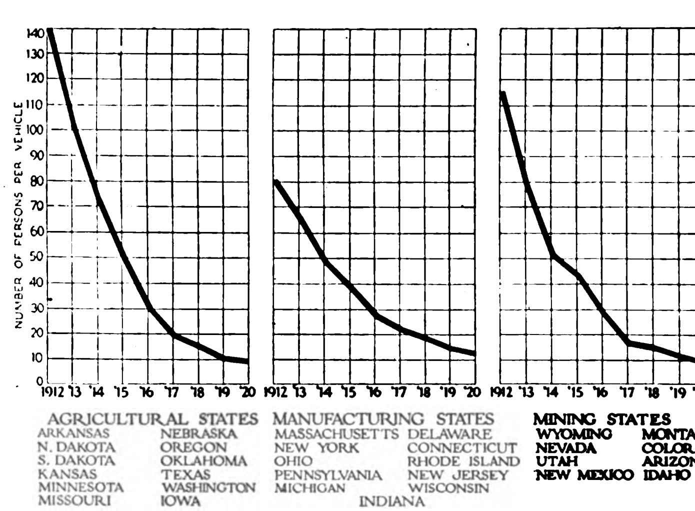
Large Gains By Large States

As might be expected, however, the largest states have made the greatest actual gain in registration during the last year. The five leaders in actual gain are as follows:

Ohio	104,366
New York	97,628
Texas	96,383
California	91,442
Illinois	90,321

Agricultural States Lead in Cars Per Capita

None of the first thirteen states in the list of cars per capita is classed as a manufac-



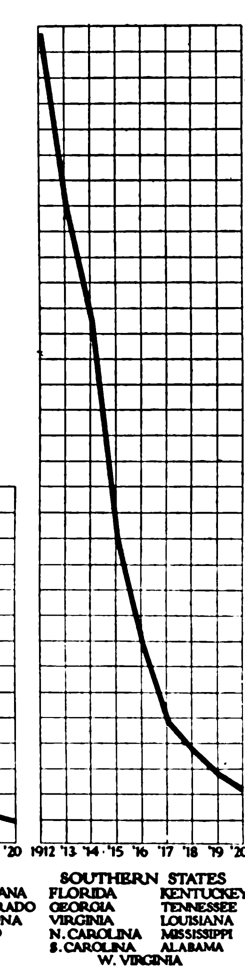


Fig. 1

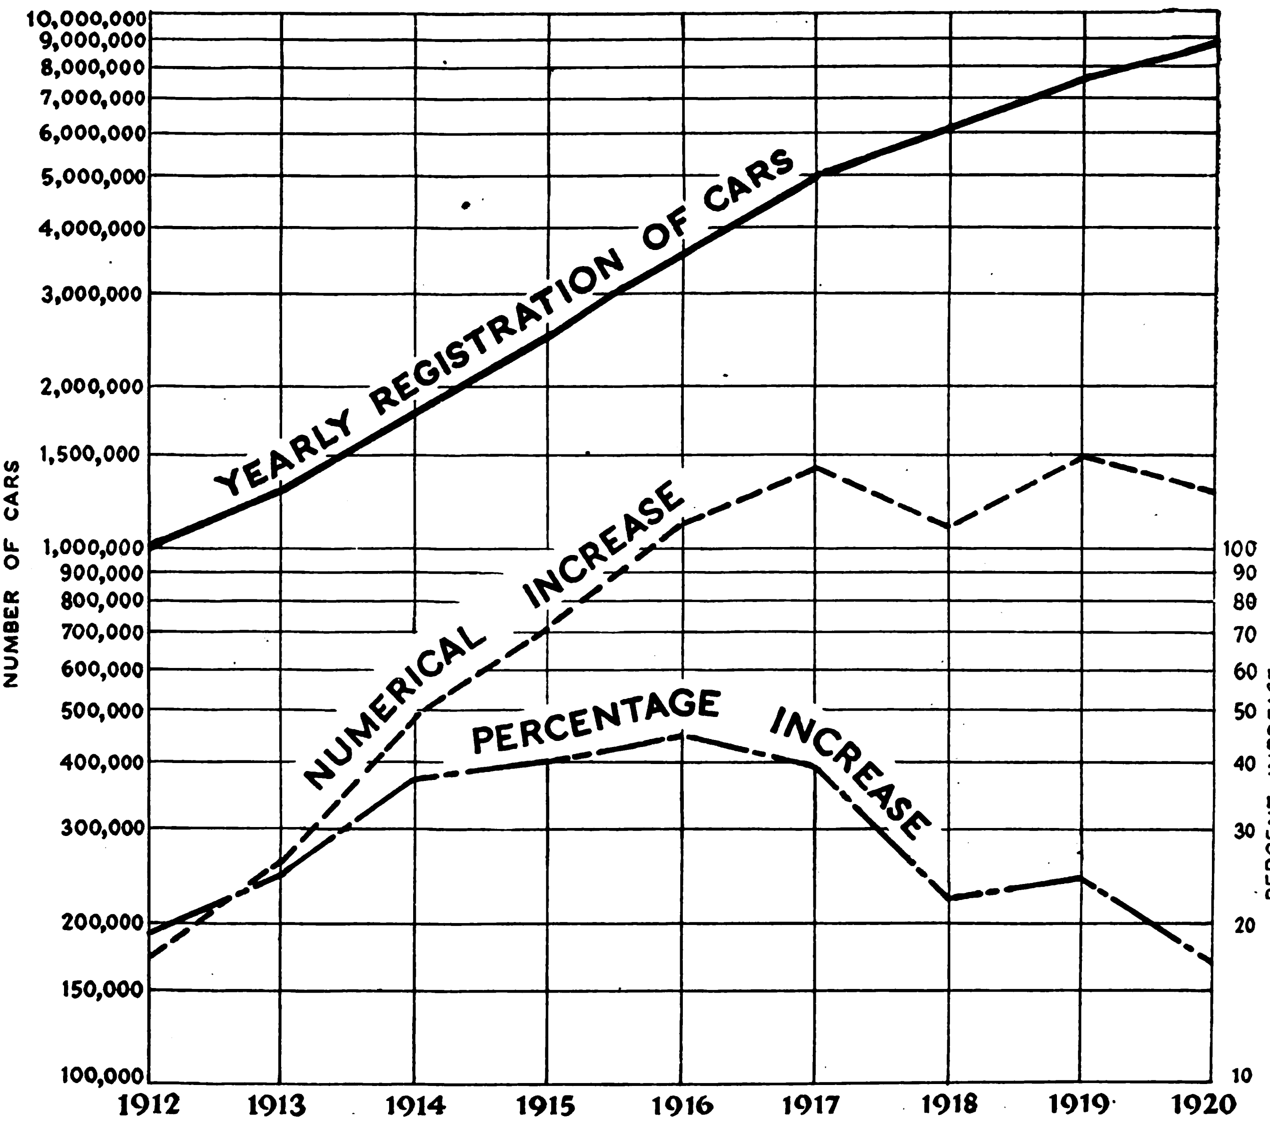

turing state. The first six in the list are predominantly agricultural states. In some of the states, such as South Dakota, Iowa and Nebraska these statistics show one motor vehicle for practically every family. It must be remembered, however, that the figures include both cars and trucks and that if a more detailed and careful analysis were possible it would probably show the farm market still to be large for both cars and trucks.

The large number of persons per car in the manufacturing districts can be attributed rather to the comparatively high cost of keeping a car and to the difficulties of storing it than to any other reasons. As municipal facilities for parking, housing and storing vehicles are improved so will the city market for vehicles be materially increased.

Michigan has the honor of being the first manufacturing state in this list, with only 8.91 persons for every vehicle, while Wisconsin is next with 8.98, followed by Ohio as noted previously.

West Virginia Makes Big Percentage Gain

The largest percentage gain was made by West Virginia with 57.2, followed by Virginia with 42.6, and Mississippi with 42.12 per cent. The ten states making the largest percentage gain during 1920 in order were: West Virginia, Virginia, Mississippi, Oklahoma, North Carolina, South Carolina, Louisiana, Texas, Tennessee and Alabama.

Every one of these states may be definitely classed as a southern state. This bears out the conclusions discussed earlier in the story that merchandising in the southern states is only in the beginning of its development.

This fact that the southern states show so large a percentage of increase should be linked up with the table showing number of persons per car. In the latter table, it will be noted, the southern states are still far behind. These facts, taken together, would indicate that the South is just beginning to develop its fuller potentialities as an automotive market and that there is still a very large field there for sales before anyone need begin even thinking about the mythical saturation point so generally discussed.

A large increase in the number of automobiles together with a depressed business situation have combined to bring very close the saturation point so far as easy sales and "order-taking" merchandising is concerned. But a close analysis of the registration figures gives no indication whatever that the real saturation point is even on the horizon. When the necessary replacements are considered, together with the potential markets revealed from a study of the registration figures, it becomes evident that there is still a very large market for motor vehicles in the United States which has as yet been developed to a slight degree. Because registrations of cars and trucks have been segregated in

only a few states for a number of years past, the only conclusions available in regard to truck registration must be based on incomplete data. In only eight states has the separate truck registration for the last four years been completely available. On the basis of these states, bearing in mind the limitations outlined, however, some interesting deductions may be made. The states in question are New York, Pennsylvania, Michigan, New Jersey, Massachusetts, Maryland, Maine and Rhode Island.

The total truck registration of these typical states since 1917 is as follows:

1917	136,356
1918	215,637
1919	288,116
1920	306,605

It is interesting to compare the percentage of this gain with the percentage gain in total vehicle registrations for the country during that same period.

	Total registration	Car registration 8 States	Trucks in 8 States
1917 ..	39%		
1918 ..	20%	13%	36%
1919 ...	23%	26%	34%
1920 ..	17%	20%	20%

These figures would indicate that trucks experienced exceptionally good years in 1918 and 1919, but that the slump hit them a little sooner than it did the passenger cars; so far as domestic distribution is concerned at least. The more uniform increase and stability of the passenger car figures might indicate more better planned and more stabilized merchandising policy in general; a merchandising system better able to withstand sudden shocks and somewhat less dependent upon abnormal demand for steady business.

The failure to continue the percentage increase through 1920 is probably due in part to after-war conditions. It was in these manufacturing states that there was the great test of transportation which did so much to prove the emergency value of the truck. But it was also in these states that there was the greatest slump in transportation demands. Many of the trucks used in these states for war-time transportation were sent west to relieve the great congestion that appeared there. Port conditions were not so urgent after the war strain was over and at the points where transportation had been keyed up to the greatest emergency, there was the sharpest slump.

Then, too, truck registration figures are complicated by the legal definition of a truck in registration laws. In some states a truck is a vehicle on solid tires. That naturally makes an incomplete showing for trucks as the use of pneumatic tire-equipped trucks increases.

Confused Registration Figures

The confused state of the various registration systems has been mentioned before. It is necessary to explain one or two points in the present figures that they may not be misinterpreted. The registrations in Minnesota, for instance, comprise merely the cars and trucks registered during the year 1920. This does not include anything like all the cars in that state, since Dec. 31, 1920, was the end of a three-year registration period. The total for the three years would not, however, present an accurate count of the number of vehicles in the state either. The three-year figure was 324,360 and is mentioned as a matter of information.

A new law was passed in this state by the voters at the last election, which provides for a yearly registration system. The methods of working out this law, however, are now being debated by the legislature, and, since the three-year registration period previously provided for has passed, there is at the present moment no registration of motor vehicles in Minnesota.

There have been only two changes of any importance since the publication of the registration figures in AUTOMOTIVE INDUSTRIES Jan. 13. These are in the cases of Florida and Maryland, the figures for which were not available before. Maryland now appears 24th in the list of total registrations instead of 25th, as in the previous list, while Florida is actually in 32nd place instead of 38th, as placed in the previous compilation.

Slight revisions appear in the case of about 10 other states, none of the changes being important enough to change the states' positions in the list of total registrations.

Some states register tractors with trucks and do not register trailers; others register trailers with trucks and do not register tractors; others register both tractors and trailers with trucks; and still others register neither trailers nor tractors in any way. These facts should be borne in mind when any calculations are being made on the basis of apparently segregated registrations.

It is the practice in some States, as well, to classify vehicles on the basis of use rather than construction.

The Agricultural Market

It is reasonable to suppose that the value of the state crop would have some general relation to the automobile population in the state. Where the value of the crop per person is large, there is an indication of potential buying power and the number of automobiles should be proportionately large. Where this is not the case, there would seem to be an excellent market, undeveloped up to the present time for one reason or another.

The values of the crops in the agricultural states during 1920 according to *Agricultural Statistics* were as follows:

Texas	$788,983,000
Iowa	783,488,000
Nebraska	522,186,000
Kansas	399,844,000
South Dakota	366,582,000
Arkansas	359,538,000
Oklahoma	329,579,000
North Dakota	220,290,000
Washington	144,422,000
Oregon	108,632,000

This list includes the chief states which are predominantly agricultural, but not necessarily those which produce the greatest crop values. They are, however, what may be classed as our chief agricultural states. Bearing in mind that these states have the fewest persons per car, it is interesting to compare the population per car with the per capita value of the crops. As noted previously, these two lists should logically correspond in a general way. Here is the way it actually works out:

State	Persons Per Car
1. South Dakota	5.24
2. Iowa	5.50
3. Nebraska	5.82
4. Kansas	6.64
5. North Dakota	7.11
6. Oregon	7.57
7. Washington	7.82
8. Oklahoma	9.91
9. Texas	10.91
10. Arkansas	29.70

	Per Capita Crop Value
1. South Dakota	$547
2. Nebraska	406
3. North Dakota	340
4. Iowa	324
5. Oregon	238
6. Kansas	224
7. Arkansas	204
8. Texas	190
9. Oklahoma	164
10. Washington	101

An examination of this table shows that the per capita crop valuation is a fairly accurate estimate of the automobile sales in these ten agricultural states. While there is, of course, some variation, it is slight except in one case. South Dakota heads the list both in cars per capita and in per capita crop value.

Iowa, though fourth in per capita crop value is second in cars per capita. This indicates that Iowa has been very thoroughly sold on automobiles and trucks, as does the numbers of persons per car figure itself. There is, however, $81 difference in the per capita crop value between Iowa and Nebraska yet Iowa has slightly more cars per capita. On this basis it would seem that Nebraska still offers a fertile field for automotive sales and that sales resistance in that state has not yet grown so strong as in Iowa.

Texas leads Oklahoma by $26 in the per capita crop value list, yet is behind Oklahoma in the persons per car classification. As before, this seems to indicate that Texas offers an excellent field for future sales, especially when these figures are considered in connection with those in a later article showing the amounts available for road building in the various states. Texas has a larger amount available for expenditure in 1921 than any other state, $60,000,000 being the sum set for building new roads in Texas during 1921.

The major exception, previously mentioned, is found in Arkansas. This state with a per capita crop value of $204 stands seventh in that list being only $20 behind Kansas which has but 6.64 persons per car, and Arkansas is $15 above Texas in this list, while Texas shows only 10.91 persons per car. Yet Arkansas stands far down at the bottom of the agricultural states in the list of persons per car, with only one car for every 29.7 persons in the state.

These figures would seem a rather large undeveloped market for cars and trucks in Arkansas; a market which has not been touched to any great extent as yet for one reason or another. Whether or not this is actually the case, the suspicion is rendered very strong by the fact that the relation between registrations and per capita crop value bears a fairly accurate proportion in each of the other agricultural states.

Motorcycles Gain Slightly

Motorcycles have been holding their own in the United States since the end of the war. After showing a very small decrease in 1919, the total registrations for 1920 went ahead of the two previous years. The total registrations in 1920 were 234,954, an actual increase of 1568 and a percentage gain of .68 per cent over 1919.

These figures do not indicate that

NUMBER OF PERSONS PER CAR, Dec. 31, 1920

State	Pop.	Cars and Trucks	Pop. per Car
So. Dakota	635,839	120,395	5.24

the motorcycle industry is standing still as might be supposed from a superficial survey. A number of factors, such as the enormous government and foreign trade work done during the war, enter into any detailed examination of the registration statistics as an indication of the present status of the industry. A consideration of these factors shows the industry to be in a healthy condition and to be progressing at a normal rate and puts a different aspect upon the actual registration figures.

There is not space in this article to analyze thoroughly the present status of the American motorcycle industry, but an article in a later issue will summarize all phases of the present situation and point out probable trends in the immediate future, based upon a careful survey of the industry as a whole.

The states which have the largest number of automobiles have also the largest number of motorcycles. This would indicate that motorcycles fill a distinct field of their own and are not competitors of the automobiles; that the motorcycle is the compliment of the automobile and that it thrives in the same places as the car and has hard going where cars are not numerous.

The ten states having the largest number of motorcycles, for instance, are as follows:

New York	29,453
Ohio	26,956
Pennsylvania	23,981
California	20,047
Massachusetts	15,143
New Jersey	11,041
Illinois	10,597
Indiana	8,823
Michigan	8,011
Wisconsin	8,002

The first four states in the motorcycle list correspond with those of the similar automobile table, while all of these first ten in the motorcycle list appear among the first fourteen in the automobile tabulation.

Tractor Registrations

While the registration of tractors and trailers is not yet general enough to form a sound basis for finding the number in use in the country, it is interesting to examine the figures available with a view to understanding the present status of the question in general. Consequently, the accompanying table is of value in showing the states in which it is possible to determine the number of tractors and trailers with any degree of accuracy and those in which figures of any kind are not available.

About ten states now register tractors separately, and one more will begin to register them in 1921. In most cases, however, the number of registrations is not a guide to the number of tractors, since the majority of these ten states register only commercial tractors or tractors which use the roads. Consequently, estimates made by reliable sources form a truer basis for determining the actual number of tractors even in the states which register them. Such reliable estimates have been used in this table wherever available.

It would be advantageous to the industry if tractors could be universally registered, but that does not mean that they should be licensed and taxed. There is one state already, for instance, that registers all tractors but does not license them. The accompanying table, however, is printed as a matter of interest and as being the best data available on this subject at the present time.

Estimated Number of Tractors

With no figures at all available from twenty-three states, and with the figures from many other states obviously inaccurate, there is no sound basis upon which to estimate the number of tractors actually in use in this country. Assuming the life of a tractor to be seven years with good care, the number at present in use would be something like 433,000, the estimate being based upon production figures. Again, however, accurate production figures are difficult to obtain, and at the present time few tractors get "good care," so that 433,000 is probably a high estimate.

There are five big tractor states for which no figures are given in the acompanying table. The total of the states shown in the table is 153,458. Estimating very roughly from the meager facts available, a good guess as to the number of tractors now in use would be something like 300,000 to 350,000.

A tractor expert estimated about a year ago that there is an immediate market for about 695,000 tractors in the country.

The table shows a total of 17,677 trailers registered in 12 states. Figuring on a population basis, these 12 states comprise about 40 per cent of the entire country. Thus, using population as a basis, it may be estimated roughly that there are 45,000 trailers now in use in the United States.

Design Tendencies in 1921 American Passenger Car Chassis

Decrease in percentage of eight and twelve cylinder models with gain in four and six type indicates tendency toward simplification, as does also the gain in percentage of unit power plants. Marked increase in pressure and splash-pressure lubrication. Less pronounced gain in I and L-head cylinders. Transmission emergency brake used on several cars.

By Herbert Chase

ANALYSIS of the specifications of American passenger car chassis for 1921 reveals no very pronounced deviation from 1920 practice. This is no doubt due in large part to the fact that the industry was too busy on production of cars early in 1920 to consider many changes in the 1921 product even if the engineering department had concluded that such changes would be desirable. It is known, however, that the engineering staff of practically all plants has been unusually busy during the past few months when production has been extremely light, so that there are apt to be more changes in the 1922 product than in the 1921, but even these do not promise to be of a radical nature, for the industry has long since reached a point where its product is so nearly standardized that pronounced changes are taboo unless their need is imperative.

Too Little Attention to Fuel Saving

Not a few engineers usually regarded as conservative consider that some radical departure in engine type will soon be forced by the exigencies of the fuel situation, but the current models of passenger cars, taken as a whole, do not indicate that the relatively inefficient use of fuel so long in evidence has been appreciated or at least considered of sufficient importance to warrant the attention it should have received. More cars are being fitted with means for exhaust heating of the inlet manifold, but even this first step toward obtaining better efficiency has not been taken by many, and by many others is applied in a very crude manner. With but few exceptions other refinements calculated to increase fuel economy are lacking, though they are fortunately receiving serious consideration by some of the more progressive manufacturers.

Tendencies Toward Simplification

A commendable tendency away from an unnecessary multiplication of cylinders which many predicted when a few concerns considered designs of this character warranted, is continuing. Less than 1 per cent* of all chassis listed now have twelve-cylinder engines, as against 4 per cent in 1917 and 2.75 per cent last year. There is also a falling off in percentage of cars fitted with eight-cylinder engines—8.5 per cent, as against 12.6 per cent in 1916 and 9.17 per cent last year. While there is a slight increase in sixes—56.8 per cent in 1920 as against 57.7 per cent this year—there is a greater increase in fours—from 30.3 to 33 per cent.

Another tendency toward simplicity is the increasing use of the unit powerplant in place of separate engine and gearset. Eighty-eight per cent of all models use this construction as against 79.5 per cent last year. One advantage thus gained is the elimination of extra shaft and universals between engine and gearbox, but this advantage has been offset in some cases by the lack of accessibility, particularly of the clutch. In some new and, in most respects, well designed chassis it is necessary to disconnect the rear axle and the transmission in order to remove the clutch. Reasonable accessibility can and should be provided without sacrificing the benefits of the unit construction. Improvements in this respect should certainly be sought after and applied, for the service problem is much too serious to be aggravated by failure to afford accessibility wherever it can be secured. To appreciation of this fact is partly due the decision of certain manufacturers to use engines with fewer cylinders and consequently less complication.

Another slight tendency toward simplification is indicated by the fact that the per cent of models using thermo-siphon cooling has increased in the past year from 29.3 to 31.8. While the advantages of this construction are no doubt worth while, it should not be forgotten that they are attained at the expense of some increase in weight, for the pump circulation makes possible the use of a smaller radiator and a cooling system containing less water.

The Light Car Notably Absent

The average wheelbase of all models is 120.77 in., this figure having varied less than 1/10 in. since 1918. Average horsepower is also about the same as last year, indicating that taxation and the cost of upkeep and fuel are not considered of sufficient moment for American manufacturers to follow the example set by British and Continental manufacturers in the production of a considerable number of cars weighing less than 1500 lb. with body, and having engines of 100 cu. in. displacement or less, many of them air cooled. While some of these cars have a tread of less than 56 in. others have standard tread. They carry two and some four passengers and in nearly all respects are of conventional construction, hence are not to be classed as cycle cars. There would seem to be possibilities in a car of this character in this country.

The use of L-head and valve-in-head engines continues to increase at the expense of the T-head, F-head and Knight types. Only 4 per cent of all models use T-head construction, as compared to 7.47 per cent last year. The so-called "F"-head, in which one valve is in the head and one in an L at the side of the cylinder, also shows a decrease from 5.68 to 3.1 per cent.

There is practically no change in the type of drive employed for the camshaft. The use of helical or spiral gears shows a slight increase from 75.2 to 77.7 per cent, whereas the use of the silent chain has increased from 18.3 to 19

*Percentage figures in this article refer to the per cent of models listed in the accompanying table, concerning which information has been supplied under the heading in question. The figures do not take into consideration the number of each or any model which the various manufacturers produce.

per cent; practically all other drives are straight spur gears, this type being used on 2.5 per cent of models this year as against 5.5 per cent last year.

Electrical Equipment

In the matter of electrical equipment the change is slight, but accessibility has been improved in some instances, for example by placing the distributor on top of the engine. There is still much room for improvement in the matter of battery location. The lesson of properly supporting this troublesome unit has been fairly well learned, but the question of accessibility is too often overlooked. The battery is often regarded as a necessary evil, and there can be no denying the fact that its life is all too short. For this reason if for no other it should be placed where it can be easily inspected and filled, for its life will depend partly upon the care given it, and it is more apt to be neglected if hard to get at.

Last year less than 1 per cent of models listed were without electric starting. This year even the small minority have seen the light and no American car is without this useful accessory. A few makes are using belt drive for the lighting generator, a practice quite general in the case of British cars. The belt drive is quiet and can be made easily adjustable, but the fact that it occasionally requires adjustment while most other forms of drive do not, except perhaps at rare intervals, is certainly not a point in favor of the belt driven type.

Single ignition shows a small gain in popularity, and is used on 92.5 per cent of models. While the advocates of dual ignition have more than doubled they comprise only 6.55 per cent of the total, as compared with nearly 70 per cent in 1913. The gain in battery ignition is of course due only in part to the merits of the system considered alone, but it is evident that its reliability has greatly increased, else the users of dual ignition would not now include so small a percentage of the total. Nevertheless it is not uncommon to hear a driver whose battery is in poor shape say that he wished the car had magneto ignition, so that this important factor would not be dependent upon what is perhaps the most unreliable element in the modern car.

Lubrication

In respect to lubrication perhaps the most important factor is the greater attention being paid to lubrication of chassis parts. Some think and many hope that the days of the grease cup are numbered. However this may be, the use of more positive means of chassis lubrication is increasing. The use of grease has been rendered much more satisfactory by providing a more positive and more easily operated means of forcing the grease to the desired point. Some still lack confidence in grease lubricating systems, however well applied, and look to the provision of means for feeding oil to the wearing parts as the most promising method of accomplishing the desired result. Oil cups with means for gradual feed are being placed on the market and at least one system of forcing oil from a central reservoir to all chassis points needing oil is being used.

In the matter of engine lubrication the statistics show a considerable increase in the percentage of cars using the splash-pressure system; 43.5 per cent of models used this system in 1920 while 60 per cent use it this year. The pressure system in which oil is forced to both main and crank-pin bearings also shows an increase from 33.3 to 39.2 per cent. Less than 1 per cent of the models now listed depend entirely upon splash lubrication.

The percentage of cars using vacuum feed has slightly increased, the statistics showing that 87 per cent of models used this system in 1920, while 88.2 per cent use it in 1921. There is a slight decrease in the use of both the pressure and gravity feed systems.

Turning now to the transmission system, we find that the use of the disk and the plate type of clutch is increasing at the expense of the cone type. No less than 92.1 per cent of American cars are now fitted with multiple disk or plate type as compared with 84.9 per cent last year. The cone type, which in Europe is much more popular than in this country, is rapidly disappearing here; 15.1 per cent of 1920 models used the cone type, but only 7.9 per cent of 1921 models employ this type of clutch. The reason for this preference is no doubt due to the fact that the disk and plate types require less attention than the cone type when they are well constructed. The use of pressed or moulded facings instead of woven fabric is becoming more general, due in part to the fact that this type of facing has a higher coefficient of friction and is said to be more durable than woven fabric.

Only slight changes are noticeable in gearsets. The vast majority of these have three speeds and many of them are fitted with air pumps for use in tire inflation. Manufacturers of stock transmission are quite generally providing means for mounting the air compressor, a standard S. A. E. base being employed.

A large number of cars now use hollow propeller shafts fitted at one or both ends with fabric disk universals, but the use of one or more all metal universal joints still predominates.

As between axle types there is apparently but little choice, although the semi-floating type is used on 34.6 per cent of models, while 34 per cent use the three-quarter type and 31.4 per cent use the full floating axle. Only very slight changes have taken place in this respect in the last year.

Final Drives

The use of the spiral bevel final drive has slightly decreased, but it is still employed by 90 per cent of all models as compared to 90.6 per cent last year. The straight bevel shows a slight decrease also, from 9.4 to 8.4 per cent, while the worm gear, which had no advocates last year, is now employed on 1.6 per cent of the models listed.

Quite a number of cars are using transmission emergency brakes, the foot brake applying only on rear wheels in these cases. The great majority of cars, however, still have both brakes on the rear wheels, but the percentage of the latter which use the contracting band is decreasing. The use of the contracting band is very rare in Europe and is losing ground in this country partly because it is more difficult to prevent dragging and partly because it catches a great deal of dirt and is sometimes torn loose by broken skid chains. The internal type is better protected but unfortunately is not so easily adjusted and relined as the external type.

The use of the wooden wheels predominates by a very large margin, but at least one manufacturer is fitting steel disk wheels as standard equipment and many others fit wire or disk wheels at the option of the purchaser. Semi-elliptic springs are used by a very large percentage of the total number of models, but a few use cantilever, platform, transverse, or three-quarter elliptic types.

Over half of the cars listed employ Hotchkiss drive. In one or two instances an adjustable spring shackle is fitted to make it possible to take up wear and thus prevent noise which would otherwise result. Improvements in this particular have long been recognized as desirable but little has been accomplished to date.

Gear ratio has continued to increase for several years past until the average now employed is 4.52 as against 4.38 last year. This is indicative of higher speed engines and a lower power factor or average engine load, a tendency which makes for lower fuel economy and one which should therefore be countenanced only if the advantage gained more than offsets the loss in fuel.

General Average and Percentage Figures Based on Data in Above Table

General Averages

Horsepower, S.A.E. rating	25.87
Bore	3.43
Stroke	4.93
Stroke bore ratio	1.43
Displacement	293.48
Wheelbase	120.77
Gear Ratio	4.52
Tires	32 x 4
Number Chassis	132
Number makes	117

Engine Starting

Electric Starter	100 per cent
Acetylene Starter	none
Air	none
Optional	none
Mechanical	none
No Starter stock	none

Fuel Feed

Gravity	4.70 per cent
Gravity Pressure	none
Pressure	7.10 per cent
Vacuum	88.20 per cent

Type of Clutch

Disk	92.10 per cent
Cone	7.90 per cent
Expanding band	none
Contracting band clutch	none
Cone	none
Electric	none

Location of Gearset

Amidship	9.50 per cent
Unit with axle	0.95 per cent
Unit with engine	88.00 per cent
Unit with torque tube	1.55 per cent

Growth of Motor Vehicle Production Capacity

Merchandising effort must be directed to supplying a market for production capacity if plant and equipment are to be efficiently utilized. Both passenger car and truck production increased during 1920, while tractor production also went ahead. 750,000 vehicle replacements estimated to be necessary at present time.

IN the present status of the automotive industry, the fact that there were produced in 1920

Passenger cars	1,906,000
Trucks	335,000
Tractors	200,000

is of minor importance. The question confronting the industry to-day is that of equalizing the capacity for production and the capacity for absorption of these vehicles.

The problem of possible absorption is not to be a part of this article. In the registration article which precedes these pages, the present status of ownership is discussed and the development to date is shown by curves. The sales executive can extend these curves according to his own ideas. There are very strong variables to be considered. The wealth and buying disposition of the people are the most important of the unknown factors. No man can determine these factors for his neighbor. We all look to the future through our own glasses. One factor in this variable can be illustrated in this way: In a highly prosperous year, such as 1919, there will be a sharp demand for new cars from owners who believe that their old car is shabby. Every sales executive knows the difference between this urge during the first and second half of 1920. The factor that caused this difference was entirely apart from anything that the automotive industry could control. Call it psychological, or by whatever name you will, it practically destroyed for the time being the replacement market.

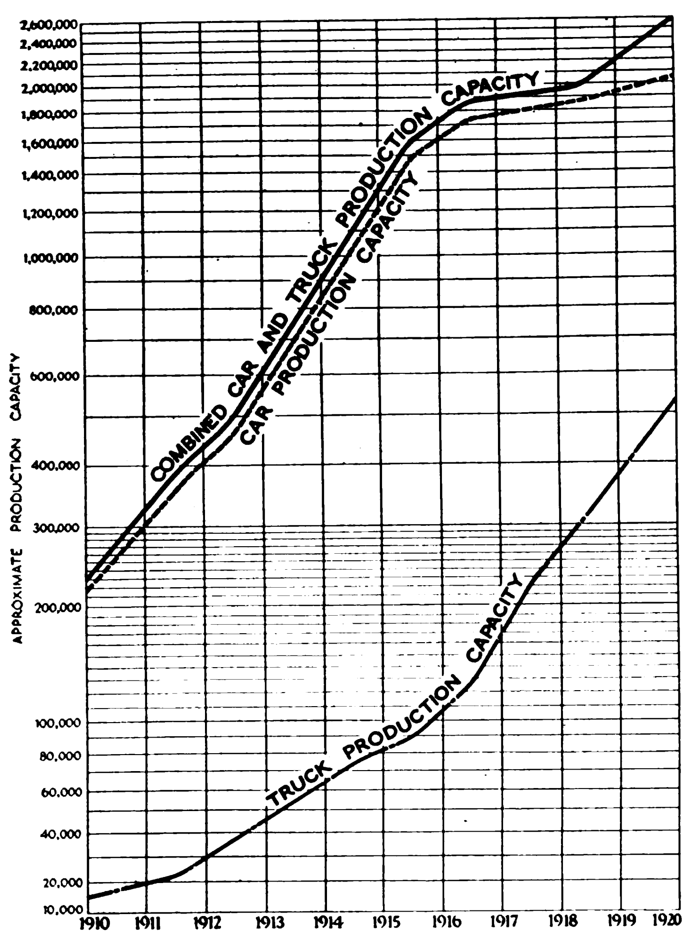

Fig. 1

In connection with this article there are printed several charts on production. Some of these are based on actual production. Others are based on production of selected years. In the latter charts the years selected are those during which we have reason to believe that the production was practically at capacity. To make this production capacity curve representative of a growing industry, the year's production has been charted as of July 1, midyear, so that the upward sweep of the chart for the latter half of the year may represent the capacity under construction. The figures for 1920 are based on actual records for the first half of the year, with allowances based on a questionnaire to a large number of manufacturers.

Present Production Problems

When the business slump hit the automotive industry along with the rest about last July, it found a very large number of manufacturers with half-completed projects for expansion and additions. Some of these unfinished projects were so large in particular cases as to contemplate a production capacity increase of 100 per cent or more. Other additions were smaller in scope, but twelve months ago a large majority of automotive manufacturing plants were not only striving for maximum production from their then present facilities, but had actually started building or expansion work of some kind.

Final production figures for 1920 showed a total of 2,241,000 cars and trucks. Production had slumped off very considerably during the last six months of the year. Consequently, it is evident that the production capacity of even the old plants and equipment was well above the actual production figure for that period. When the partly completed additions are taken into consideration as well—additions which were in many instances practically ready to start production—the actual production capacity figure mounts even higher.

The chart shown in Fig. 1 indicates that this potential

Fig. 2

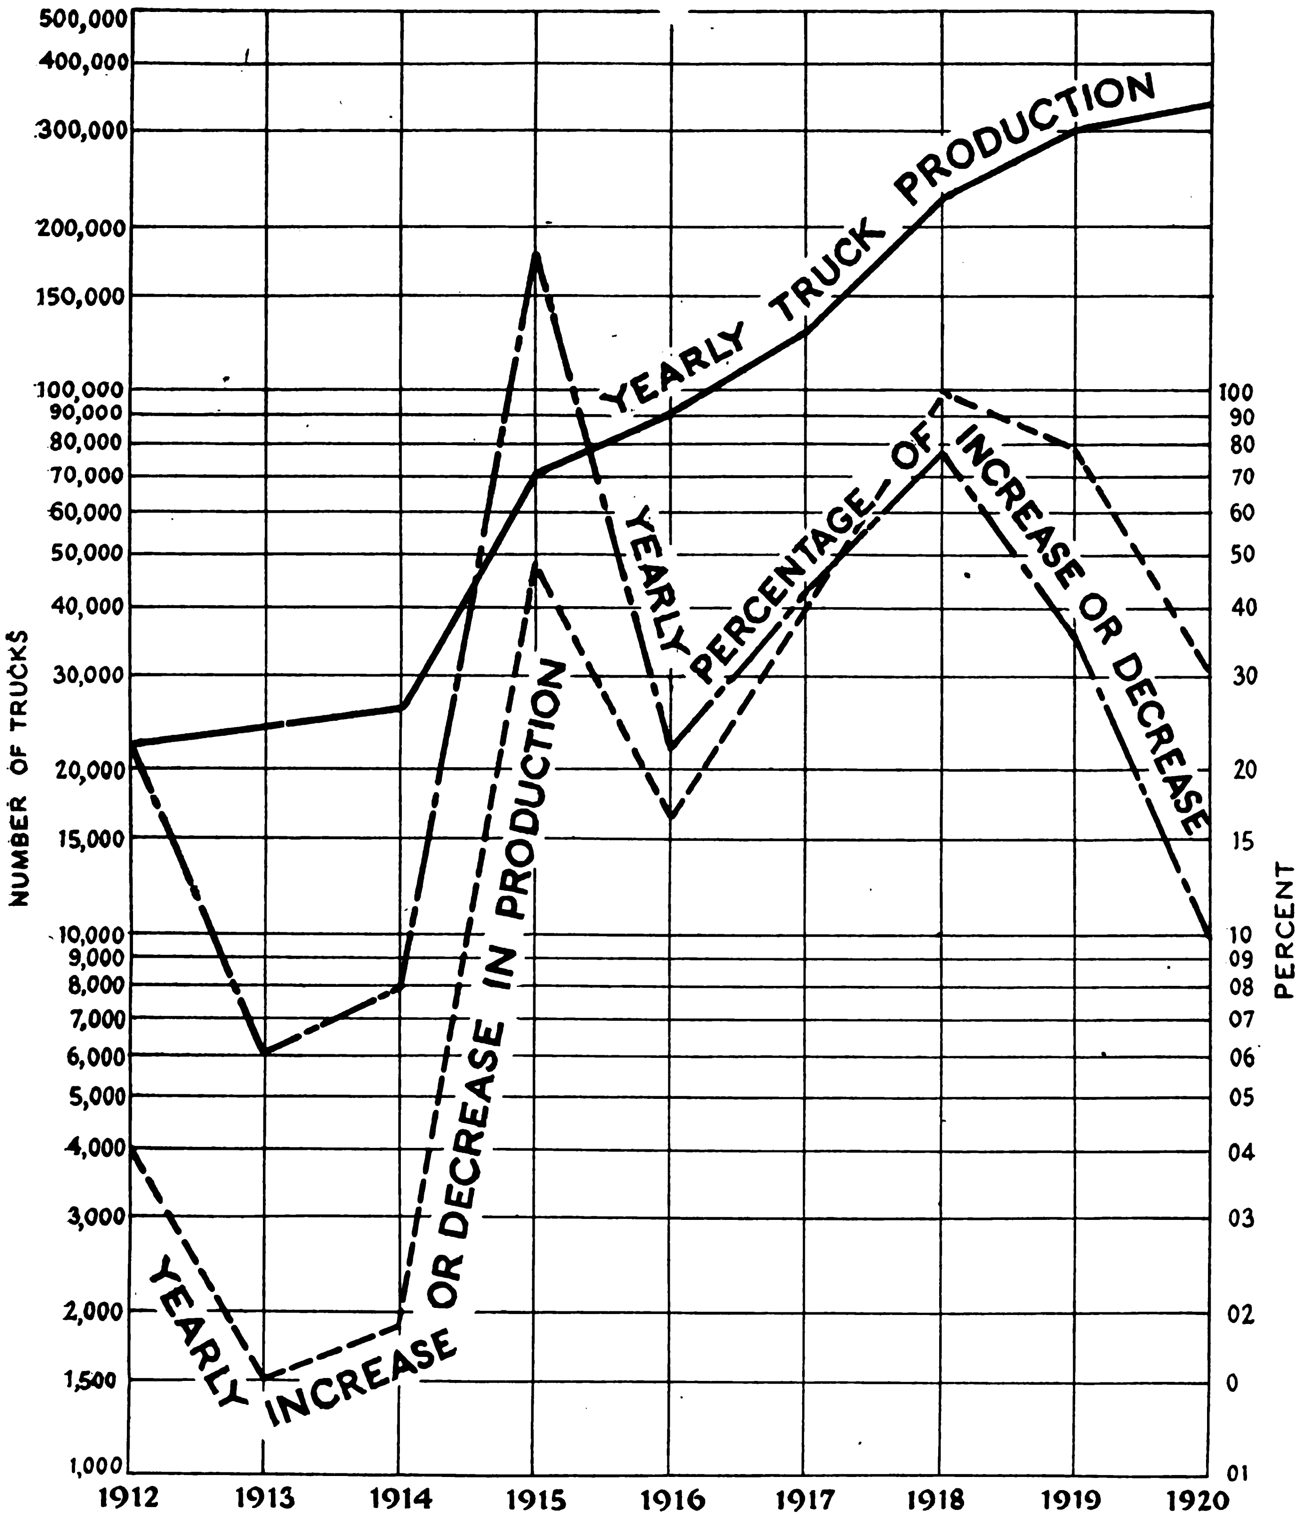

Fig. 3

capacity at the end of 1920 was 2,660,000 cars and trucks, 419,000 more than the number of vehicles actually produced. In other words, to operate their plants at maximum efficiency, the automobile manufacturers will have to provide a market for 419,000 cars and trucks more than were produced during 1920.

To do this during 1921 would be a very large task, but to lay a foundation for the future is both possible and necessary. One fact should be recognized by manufacturers, however, in planning for future production and sales development, namely, that one of two things must take place if every manufacturer is to prosper to the fullest extent.

1—Markets, either domestic or foreign, must be developed to absorb an actual yearly production of this size before any additions to plant capacity are made;

(or) 2—This potential production capacity must be reduced by turning the buildings and equipment to manufacturing other materials or units.

What will actually happen, however, will probably be neither of these things. Instead few manufacturers will probably be able to "prosper to the fullest extent of their production capacity" for some time to come. Each one is likely to prosper more nearly to the extent of his merchandising capacity during 1921.

As individual merchandising effort becomes more effective and potential markets are more fully developed,

however, the status of the industry as a whole will be improved and facilities will be provided for the absorption of the production of its entire capacity.

A study of the registration figures and an analysis of the possibilities of properly organized foreign merchandising point strongly to the fact that the first alternative mentioned can readily be achieved if intelligent and efficient effort is put forth. There are undoubtedly potential markets for more cars each year than would be represented by the production of all the plants working at their full capacity as shown by the highest figure in the production capacity chart. And as the production men struggled during the last few years to meet the demands of the sales department, upon the sales department now rests the fundamental task of meeting the requirements of the production possibilities.

The chart shown in Fig. 2 shows the climb of actual car production since 1903, together with the yearly increase or decrease in number and percentage. The production line itself is marked by a steady climb, unbroken except for the war year 1918. The largest per cent of increase in production was in 1909, while the largest increase in actual numbers occurred in 1919.

Yearly truck production shows an even more steady growth than that of passenger cars, since the war was an impetus rather than a retardation to truck production. Yet the production curves for both cars and trucks show exactly what would be expected in the case of a young, growing industry. This is shown in Figs. 2 and 3. At some future time the production line for both cars and trucks may be expected to become almost horizontal, but there is no indication that this will occur within the next few years.

Truck production showed its greatest percentage of increase during 1915, while the greatest actual increase came in 1918, when the demands of the U. S. Government for trucks were added to those of our allies.

Replacements

In considering future markets and production, the question of replacements inevitably plays an important part. Various difficulties enter into an accurate estimate of replacements, but figures close enough to indicate general trends can be compiled. The following table shows the number of replacements in the United States during the last six years. In obtaining these results exports have been taken into consideration. Replacements during this period were approximately as follows:

Year	Registration	Increase	Built	Exported	U. S.	Scrapped
1914	1,768,000	......	569,000	26,000	543,000	......
1915	2,479,000	708,000	892,000	64,000	828,000	120,000
1916	3,584,000	1,105,000	1,583,000	81,000	1,502,000	397,000
1917	4,992,000	1,408,000	1,868,000	80,000	1,788,000	380,000
1918	6,105,000	1,113,000	1,153,000	47,000	1,106,000	......
1919	7,596,000	1,491,000	1,974,000	82,000	1,892,000	401,000
1920	8,915,000	1,319,000	2,241,000	172,000	2,069,000	750,000

This estimate does not take into consideration the number of cars in the hands of dealers on Jan. 1, the date on which the table is based.

The apparent absence of replacements in 1918 is due probably to a very widespread rejuvenation of old cars during the war and a somewhat decreased production during the same period. It may also be attributed somewhat to the previous uncertain condition of registration figures in one or two States, which consequently showed rather complete registration figures for the first time.

Rise in Value of Product

The chart in Fig. 4 shows the steady rise in the wholesale value of the cars and trucks manufactured since 1910. As would be expected the highest figure is that for 1920, the two billion mark being passed for the first time during last year. This is an increase of about 13.31 per cent over 1919.

Tractor production is not as well defined as is production in other lines in the automotive industry. The record of production available is accurate for the four years, 1916 to 1919. The figures were gathered by Federal Bureau of Public Roads. There are no accurate figures available for 1920. The figures used in the following tabulation for 1920 are from records of parts makers who supply tractor manufacturers. This is the tabulation carried out for 1920:

	1916	1917	1918	1919	1920
Manufactured	29,670	62,742	132,697	164,590	200,000
Sold in the U. S...	27,819	49,504	96,470	136,162	150,000
Sold for export ...	.....	14,854	36,351	19,693	15,000
On hand Dec. 31 ..	.....	15,525	15,401	27,740	60,000

So far as parts makers have heard from their customers, the prospects for 1921 are roughly that about 75 per cent of 1920 production will be turned out during 1921.

The increase of the potential capacity of the tractor industry is difficult to estimate. There is no organization which has this information. Recently a number of tractor manufacturers were asked to estimate the increased capacity of the industry. Most of them replied that they lacked the information necessary to make such an estimate. The sales manager of one of the oldest and largest manufacturing plants in the industry replied that his plant had an increased capacity of 570 per cent over Jan. 1, 1915. His estimate was that the capacity of the industry had been increased ten to fifteen times during the period mentioned.

Another large manufacturer estimated the increased capacity of the industry during this period as 400 per cent.

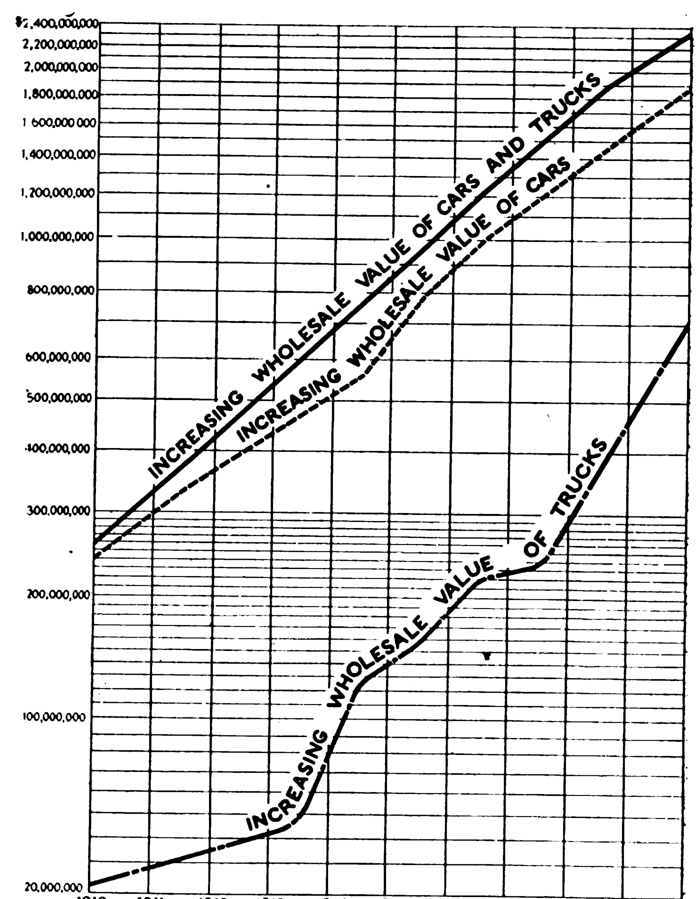

Fig. 4—Increasing wholesale value of cars and trucks plotted by big production years

Automotive Exports from England, France and Italy Increase

Value of complete cars and trucks exported from England in 1920 four times that of 1919 total, while Italy exports two-and-one-half times as much during first half of 1920 as during entire previous year. France also shows big gain, passing the billion francs mark for first time.

THE value of exported automotive products rose during 1920 for England, France and Italy. About four times as many complete cars and trucks were exported from the United Kingdom during 1920 as during 1919. The value of tires and tubes exported during 1920 shows a total of about 150 per cent more than the previous year.

French automotive exports increased in value 971,970,000 francs over the 1919 total, while Italian exports more than doubled in value. The tables presented in this article give all the detailed data available at this time on the exports from these three countries.

French Exports

In 1913, the last year unaffected by war conditions, the French automobile industry exported to the value of about 227 million francs. The following year the volume of business was on an increasing scale until the war clouds burst, but with five months of war the total was less than for the preceding year. During 1919 the volume of business was higher than in 1914, while by 1920 all records had been broken. Figures for only the first eleven months of the year are available, but these show a total of 1096 million francs, and on the assumption that December is equal to the average of the previous eleven months, this gives a total in round figures of 1200 million francs of export business for the year.

These figures give the impression of a most wonderful revival on the part of France, particularly in view of the fact that general depression prevailed for nearly one-half of the past year. In order to completely understand these figures, however, it is necessary to bear in mind the method under which exports are valued by the French authorities. The official figures consider the metric tonnage of automobiles exported, and a value is given to these for statistical purposes. In 1914 the value per metric ton for all classes of passenger cars was 850 francs. By 1915 this had been increased to 1150 francs; in 1916 the value

(a) Includes parts. (b) Includes tires and tubes.

Note: Figures during the war period include merchandise exported for Governments of the Allies but not for British Forces.

was 1500 francs, and in 1920 a metric ton of automobiles was considered to be worth 3000 francs.

If the fact is taken into consideration that the value of French automobiles exported to foreign countries is now calculated at about 3.5 times higher than 1914, it is found that the number of cars sent out of the country is really less than before the war. The coefficient adopted by the French Treasury Department is roughly correct, the only objection that could be made against it being that it is rather high for the cheaper grades of cars, for which a coefficient of 2.6 might have been employed.

The figures of French automobile exports during the war, which are here published for the first time, are of considerable interest. Russia headed the list in 1915 with nearly twenty-four and a half million francs worth of vehicles—evidently army trucks. The following year this amount had grown to more than sixty-two million francs; for 1917 it dropped to less than 21 million francs, and in 1918 France sent nothing to Russia. In three years Russia received nearly 108 million francs worth of French automobiles; how much of this she paid for is not known.

The year 1918 was the low water mark of French automobile exports, the total being only slightly more than four million francs. At that time, of course, the French factories were fully occupied with war orders, and Russia having fallen away no war trucks were being sent to that country.

Italian Exports

THE Italian automobile industry reached the high water mark of its export business in 1917, when trucks and touring cars to the value of 114,978,805 liras were sent out of the country. The great bulk of this business consisted of army trucks supplied to France and England, with a small number to the American Forces then in France.

The year 1918, the last of the war, showed a falling off in the volume of export business, the figure being rather more than 45 million liras; this was owing to the fact that the Italian automobile factories were set to work to repair the losses sustained in the Caporetta disaster. The year 1919, the first under peace conditions, showed a wonderful revival with 43.5 million liras worth of exports, both the number and the value of the vehicles being higher than in 1914.

As the last figures available for the Italian industry only cover the first six months of 1920, the effect of the labor troubles during the fall of that year are not yet known. The year began well, and had the second half been as flourishing as the first half, Italy would have reached a record under peace conditions.

Italian Automobile Exports

from 1910 to 1920.

Year	Number of Trucks	Number of Pass. Cars	Value of Trucks Liras	Value of Pass. Cars, Liras

1920 for 6 months	Trucks and Pass. Cars	2,234	52,759,953	

Italy is the European nation having the greatest proportion of export to home business, and at the present time is sending probably 70 per cent of her output abroad. It has been declared that Italian manufacturers are obliged, under Government decree, to export 90 per cent of their production. This is not correct, for although a law to this effect was proposed, it was never put into operation.

Italian exports for the first half of 1920 were:

Italian Automobile Exports

Before the war Great Britain was Italy's best individual client, but France, Germany, Austria, Switzerland and the South American States were all big purchasers. No detailed official post-war statistics have been published which would show the changes that have taken place.

Italy, it is estimated, had 50,000 men directly engaged in the automobile industry in 1920, compared with 70,000 at the height of the war, and 10,000 in pre-war days. The productive capacity of the factories has therefore increased five times.

A REPORT made by the Red Sociedad Automovolistica Sevillana, of Seville, Spain, shows that the 1920 automotive registrations for that city alone were 877 passenger cars, 220 trucks and 30 motor buses. The three leading makes of cars were shown as of American manufacture.

Design Tendencies in 1921 British Passenger Car Chassis

Light car with 100 cu. in. or smaller engine increasingly popular due to lower tax and upkeep cost. Return to pump circulation predicted. Majority of new makes prefer cone clutch to plate type. Fewer four speed gearsets and transmission brakes. Use of spiral bevel increasing.

By M. W. Bourdon

THE accompanying tabulated specifications of British passenger cars gives clear evidence of the increasing popularity of the light two and four-passenger car with a four-cylinder engine of less than 100 cu. in. capacity. As will be seen, over twenty-five makers are producing these small chassis, and though the majority are made in plants with small outputs, the aggregate production is variously estimated at 500-750 per week. The average weight of the most popular examples is approximately 1400 lb. for the two-seaters and 1700 lb. for the light four-passenger models complete with bodywork. The wheelbase varies from 90 in. to 110 in., while the track varies from 44 to 56 in.

The table does not include cyclecars, of which—with three or four wheels and motorcycle type single or V twin engines, belt, chain or shaft transmission—there is an almost endless number of makes, the majority issuing from small plants, some with an output of but two or three chassis a week. But the table includes such well-known and popular makes as the 12-hp. A.B.C. and the 8-hp. Rover, both of which, despite their horizontally opposed twin-cylinder air-cooled engines, are recognized as light cars by reason of their controls, transmission and chassis being on lines generally adopted in larger types.

These light two or four-seaters are making a forcible appeal to British users by reason of their low cost of upkeep, economy in fuel and the smaller annual tax to which they are subject on the new scale of £1 (say $5) per horsepower, the latter calculated on the formula $\frac{D^2 N}{2.5}$, where dimensions are in inches and D equals diameter of cylinder bore and N the number of cylinders. The fact that stroke is not taken into consideration in the official formula has not led to any marked increase in piston speed, even in recently designed engines.

Stroke-bore ratios have not, in fact, increased in British cars of any size, popular sizes being usually in the neighborhood of 1.7 or 1.8 to 1. The longest stroke among British engines is 160 mm. (6⅛ in.), employed in the Sizaire-Berwick, which has a bore of 95 mm. (3¾ in.). But several makes have a stroke of 150 mm. (5⅞ in.), notably Sunbeam, Star and Vauxhall.

There have been one or two additions since 1919 to the list of "super-grade" chassis, the new Sheffield Simplex and the Leyland being prominent in this respect. The first mentioned is the first passenger car engine to have the Ricardo trunk piston, while the latter is the first British car with eight cylinders in line. Among more reasonably priced cars of recent design the 18-hp. Phœnix is noteworthy, for while it has an overhead camshaft and other features conducive to volumetric and general efficiency it is designed from a production standpoint, and among British chassis is considered in the forefront in this regard.

Dealing with design features generally, there has been a slight increase in the percentage of four-cylinder engines (76 as against 66); this is not due to any maker discarding the six but to an increase in the number making fours. Air cooling has made no headway during the year; in fact, except for cyclecars, it has receded, and no British car larger than the 12-hp. A.B.C. has other than water-cooled cylinders. Nor has there been any increase worthy of mention in the proportionate number of detachable head engines. They comprise 49 per cent of the whole number, 40 per cent of those with loose heads having the cylinder barrels cast as a unit with the upper half of the crankcase. In one or two instances (the H.E. is an example) the detachable head has the valve caps usually associated only with integral heads.

As regards valve arrangement, the L head cylinder predominates to even a greater extent than last year, some 72 per cent of engines being so equipped as compared with 62 per cent twelve months ago. Percentages indicate that valves-in-the-head engine has decreased in favor, for the table shows only 21.5 per cent of engines with overhead valves against 31 per cent last year. But actually, judged by the standard of cars produced, they have increased, for they are embodied in the designs of firms such as Wolseley and Standard, each with outputs exceeding the aggregate of those of a selected dozen or more of the smaller plants making L head engines. In the operation of overhead valves, the overhead camshaft is favored, viz., 57 per cent, as against 43 pushrods. With the latter all makers except one (Dawson) have rockers between cams and valve stems.

The T head engine has disappeared entirely from passenger car engines, but the pair-cast cylinder is still found in 4 per cent of four-cylinder motors, notably in one of the smallest of these, the 10-hp. Singer.

Aluminum pistons have made no headway, though they are found in 26 per cent of engines, the types in this material most generally favored being the Ricardo "slipper" design and the split skirt pattern, with an internal cast iron expansion ring close to the lower edge of the skirt. Both of these have almost an entire freedom from piston slap when cold. Only seven makers fit a scraper ring at the bottom of the skirt, but approximately 40 per cent arrange for the lowest of the compression rings to serve the same purpose, by beveling the lower edge of its slot and drilling small holes through at 45 deg. from bevel to interior with the inner end of the hole lower than the top.

In pre-war designs 90 per cent of wrist pins were fixed in the piston bosses, but at present only 52 per cent are thus secured, for there is a pronounced tendency either to follow American practice and fix the pin in the connecting rod or to allow it to float in both piston and rod. The latter arrangement is the most popular variation from hitherto standard practice, and 28 per cent of engines have floating wrist pins.

Hollow shaft (pressure) lubrication has not gained ground on a percentage basis, but in trough systems it is becoming increasingly prevalent to provide direct leads under pressure from the oil pump to the crankshaft main journals and frequently also to the camshaft bearings. Thus, while 51 per cent of British engines have trough lubrication for the big-ends, fully 50 per cent of these have direct leads to the crankshaft journals or camshaft bearings, if not to both. There is no pronounced tendency when the hollow shaft system is adopted to carry the oil up to the small end of the connecting rod, both this and the cylinder walls depending upon splash. Plunger oil pumps are not particularly favored by British engine designers. Only some 21 per cent have the oil circulated by this means. The twin pinion gear pump is by far the most popular. No attempt has been made by British passenger car makers to adopt a dry sump system of lubrication or to cool the oil by any means other than by longitudinal fins cast at the bottom of the crankcase sump.

In regard to fuel feed, the reason why the gravity system shows an advance in favor as compared with last year (56 per cent as against 48 per cent) is the increase in the number of small cars for which the vacuum system has not been considered necessary or desirable. Complaints have certainly been made against the vacuum feed on account of the occasional derangement of its mehanism, but criticism on this score has not had any effect in decreasing its number of adherents or preventing it from being adopted by makers previously favoring gravity or pressure systems. The desirability of making the vacuum tank larger and capable of being filled direct, so that the fuel can be fed by gravity therefrom when the mechanism fails, has not been seriously considered, and only one maker, namely, Sizaire Berwick, has a vacuum tank of other than normal size. In the case mentioned the tank is cylindrical and horizontal and holds 1½ Imperial gallons.

In water circulation systems there is discernible a slight tendency to return to the pump, but this inclination is only just commencing, and the thermo-syphon system still predominates. Forty-eight per cent of cars have thermo-syphon pure and simple, while 8 per cent are termed "assisted" thermo, having a belt driven water accelerator, usually at the rear end of the fan spindle, the rotor being located within the cylinder water jacket. This assisted thermo system is, however, coming to be recognized as a very poor substitute for the pump arrangement, where the pump is really efficient in serving its purpose and is provided with a direct mechanical drive.

Magneto ignition continues to hold its own, being standard on 94 per cent of makes, 5 per cent of which have a battery system in reserve. Battery systems alone are used on only 6 per cent of cars, and Wolseley, who specifies it, is still fitting magnetos. There are indications, however, that battery ignition will be found in increasing numbers before twelve months are past, if one may judge by hints thrown out by the two or three electrical firms who are standardizing an equipment of this type.

In connection with distribution gearing the silent chain is used in 55 per cent of cases, but in only half the number of these is any adjustment provided.

Turning to transmission details, the single plate or disk clutch is represented on only 27 per cent of cars as compared with 41 per cent last year, but here again this does not infer that it is falling into disfavor among those firms who have adopted it. Rather is it the case that the majority of new makers have preferred to use the cone type. There has been a slight falling off in the number of four-speed gearsets, for while twelve months ago these appeared on 59 per cent of cars, only 50 per cent have them at present.

The increasing use of fabric disks for universal joints is a pronounced tendency of British design. On open propeller shafts 28 per cent have disk joints at both ends, in some cases the flexibility of the disks being considered sufficient to warrant the elimination of a sliding joint to allow for variations in centers with spring deflection.

Metallic universals show improvement in increase of bearing area and lubrication. It is by no means infrequent to find the casings of such joints supplied with oil directly from the gearset or the back axle, while, where hand replenishment is called for, it is now rarely needed on account of better provision for retaining lubricant within the casings. When leather sleeves are used to prevent escape of oil between joint casing and shaft they are far more efficient in their purpose than hitherto.

As was expected, 1920 has shown a considerable accession to the ranks of those makers using spiral bevels for the final drive, and, as compared with only 33 per cent last year, 46 per cent now have spiral bevels in the rear axle; both straight bevels and worm have given way, the latter appearing in 9 per cent fewer cars than at the end of 1919.

Another pronounced tendency occurs in connection with brakes, for whereas before the war it was exceptional to find a British car with both sets applying to rear wheel drums, only 39 per cent now have a transmission brake; but rear wheel brakes, whether there be one set or two, are internally in 90 per cent of cars. The external band brake finds favor in only a few cases, though among these are the Daimler cars. The latter, however, have a transmission brake applied by lever, the band brake on the wheel drums being pedal operated.

In suspension systems the semi-elliptic spring is still predominant, though the quarter elliptic is increasing in favor for cars of all sizes and powers and seems likely to displace both semi-elliptics and cantilevers in popular priced jobs. The wood wheel is fast disappearing, its place being taken by the pressed-steel hollow-spoked variety and the single disk. The latter is standard on 20 per cent of cars as compared with 20 per cent wire spoked and 56 per cent pressed steel. Strangely enough the wire spoked variety is, generally speaking, used on only the cheapest and the most expensive cars. On the former it is, however, merely a laced spoke wheel on cycle lines, whereas for high-class cars the Rudge-Whitworth and Dunlop wheels are favored.

Eighty per cent of British cars have a belt drive for the electric generator, a fact which is by no means to the credit of British designers when one considers the advantages of direct drive and the ease with which it can be arranged.

While two-unit electric systems vastly predominate, the one-unit arrangement shows a slight increase in favor—mostly, however, in connection with engines up to 100 cu. in. in capacity.

Unlike American and Continental cars, only 25 per cent of British make have the unit system of engine and gearset. Four per cent and 3 per cent of gearests are on back axle and torque tube respectively, while 68 per cent are separately mounted. Sixty per cent of the latter are separate units in the main frame; sub-frames are used to carry both engine and gearset in 30 per cent of the remainder, while 10 per cent of separate gearsets have a sub-frame to themselves. Ball bearings are favored more than the roller type for both gearsets and back axles, though of gearset layshafts 70 per cent have plain bushes and the pilot bearing is also plain in an equal number.

Non-Ferrous Metal Specifications

(Excerpts from Report of S. A. E. Standard Committee)

WHITE BEARING METALS

Specification No. 10, Babbitt

Composition in percentage:

Tin	90.00 to 92.00
Copper	4.00 to 5.00
Antimony	4.00 to 5.00
Lead, max.	0.35
Iron, max.	0.08
Arsenic, max.	0.10
Bismuth, max.	0.08
Zinc	None
Aluminum	None

This analysis applies to the metal in the ingot form. When finished bearings are purchased a maximum of 0.6 per cent lead is permissible in scraped samples provided a lead-tin solder has been used in bonding the bronze and the babbitt.

General Information

This babbitt is very fluid and may be used for bronze-backed bearings, particularly for thin linings such as are used in aircraft engines. It is also suitable for die castings.

Specification No. 13, Babbitt

Composition in percentage:

Tin	4.50 to 5.50
Antimony	9.25 to 10.75
Copper, max.	0.50
Lead	84.00 to 86.00
Arsenic, max.	0.20
Zinc	None
Aluminum	None

General Information

This is a cheap babbitt and serves successfully where the bearings are large and the service light. It should not be used as a substitute for a babbitt with a high tin content. It is also suitable for die castings.

ALUMINUM ALLOYS

Specification No. 30

Composition in percentage:

Aluminum, min.	90.00
Copper	7.00 to 8.50
Zinc, max.	0.20
Silicon, Iron, Zinc, Manganese and Tin, max.	1.70
Other Impurities.	None

General Information

The tensile strength of test-specimens about ½-in. diameter of this alloy cast in sand and tested without machining off the skin should be about 18,000 to 20,000 lb. per sq. in. and the elongation 1 to 2 per cent in 2 in.

This is a light alloy having a specific gravity of about 2.83 and is used more extensively in the automotive industry than all other light casting alloys combined. A shrinkage of 0.156 (5/32) in. per ft. should be allowed in pattern designs. This alloy is used for crankcases, oil-pans, steering-wheel spiders, differential carriers, transmission cases, camshaft housings, hub-caps and similar parts.

Specification No. 31

Composition in percentage:

Aluminum, min.	81.00
Copper	2.25 to 3.25
Zinc	12.50 to 14.50
Silicon, Iron, Manganese and Tin, max.	1.70
Other Impurities.	None

Drive: Sp. Bev. spiral bevel. **Wheels:** Wood, detachable wood; Steel, spoked steel (Sankey type) Disk, steel disk (Michelin type). **Rear Springs:** El, elliptic; Cant. cantilever; Plat, platform (½ elliptic joined a transverse spring); Trans. transverse (Ford type). **Brake Location:** F. on front wheels; R. on rear wheels; Tr. on transmission.

Non-Ferrous Metal Specifications

(*Continued from page 326*)

General Information

The tensile strength of test-specimens about ½-in. diameter of this alloy cast in sand and tested without machining off the skin should be about 25,000 to 30,000 lb. per sq. in. with an elongation of more than 1 per cent in 2 in.

The specific gravity is about 3.0 and a shrinkage of 0.156 (5/32) in. per ft. should be allowed in pattern designs.

This alloy is used extensively in England for such parts as crankcases, oil-pans, steering-wheel spiders and transmission cases.

Specification No. 32

Composition in percentage:

Aluminum, min.	85.50
Copper	11.00 to 13.50
Zinc, max.	0.20
Silicon, Iron, Zinc, Manganese and Tin, max.	1.70
Other Impurities.	None

General Information

The tensile strength of test-specimens about ½-in. diameter of this alloy cast in sand and tested without machining off the skin should be about 19,000 to 23,000 lb. per sq. in. and the elongation will be practically nothing.

The specific gravity of this alloy is about 2.95 and a shrinkage of 0.156 (5/32) in. per ft. should be allowed in pattern designs. This alloy is used for manifolds, pumps, carbureters, cylinders and other parts which should be free from leaks and where the brittleness of the alloy is not objectionable.

Specification No. 33

Composition in percentage:

Aluminum	88.00 to 92.00
Copper	6.00 to 8.00
Zinc, max.	2.50
Iron, max.	1.50
Silicon, Manganese and Tin, max.	0.75
Other Impurities.	None

General Information

The tensile strength of test-specimens about ½-in. diameter of this alloy cast in sand and tested without machining off the skin should be about 19,000 to 21,000 lb. per sq. in. with an elongation of 1 to 2 per cent in 2 in.

This is a light alloy having a specific gravity of 2.83 to 2.86 and is used extensively in the automotive industry. A shrinkage of 0.156 (5/32) in. per ft. should be allowed in pattern designs.

This alloy is similar to Specification No. 30 and is used for crankcases, oil-pans, steering-wheel spiders, differential carriers, transmission cases, camshaft housings, hub-caps and similar parts.

CAST BRASS ALLOYS

Specification No. 40 (Old No. 27), Red Brass

Composition in percentage:

Copper	83.00 to 86.00
Tin	4.50 to 5.50
Lead	4.50 to 5.50
Zinc	4.50 to 5.50
Iron, max.	0.35
Antimony, max.	0.25
Aluminum	None

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	27,000
Yield point, lb. per sq. in.	12,000
Elongation in 2 in. or proportionate gage length, per cent	16

This is a free-cutting brass with good casting and finishing properties.

(*Continued on page 328*)

Non-Ferrous Metal Specifications

(*Continued from page* 327)

Specification No. 43 (Old No. 29), Manganese Bronze

Composition in percentage:

Copper	53.00 to 62.00
Zinc	38.00 to 47.00
Lead, max.	0.15

This metal may be hardened by the addition of small amounts of tin, iron, manganese, aluminum or combination of these metals. The most importance should be placed on the following minima in physical requirements:

Ultimate strength, lb. per sq. in.	60,000
Yield point, lb. per sq. in.	30,000
Elongation in 2 in. or proportionate gage length, per cent	15

General Information

This alloy is intended for use in castings where strength and toughness are required. It is equivalent to the copper-zinc alloys commercially known as Cast Manganese Bronze or its equivalents, such as Cast Tobin Bronze and Cast Naval Bronze.

Specification No. 41 (Old No. 28), Yellow Brass

Composition in percentage:

Copper	62.00 to 65.00
Lead	2.00 to 4.00
Zinc	31.00 to 36.00
Tin, max.	1.00
Iron, max.	0.50
Aluminum	None
Other impurities	.025

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	25,000
Yield point, lb. per sq. in.	12,000
Elongation in 2 in. or proportionate gage length, per cent	20

This alloy is intended for use in commercial castings where cheapness and good machining properties are the main considerations.

Specification No. 42, White Nickel Brass

Composition in percentage:

Copper	55.00 to 64.00
Nickel, min.	18.00
Iron, max.	0.35
Aluminum	None
Other Impurities.	0.25
Zinc	Remainder

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	30,000
Elongation in 2 in. or proportionate gage length, per cent	20

This brass is intended for use for trimmings or other parts requiring a metallic-white finish. The higher the nickel content, the more permanent will be the color.

Bronze Alloys

Bearings or gears made of bronze alloys should be used only against hardened steel.

Specification No. 62 (Old No. 43), Hard Cast Bronze

Composition in percentage:

Copper	86.00 to 89.00
Tin	9.00 to 11.00
Lead, max.	0.20
Iron, max	0.06
Zinc	1.00 to 3.00

Non-Ferrous Metal Specifications

(*Continued from page* 328)

General Information

Good castings made of this bronze should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	30,000
Yield point, lb. per sq. in.	15,000
Elongation in 2 in. or proportionate gage length, per cent	14

This alloy is suitable wherever a strong general utility bronze is required. It may be used for severe working conditions where heavy pressures obtain, as in gears and bearings.

Specification No. 63, Leaded Gun Metal

Composition in percentage:

Copper	86.00 to 89.00
Tin	9.00 to 11.00
Phosphorus, max.	0.25
Zinc and Other Impurities, max.	0.50
Lead	1.00 to 2.50

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	30,000
Yield point, lb. per sq. in.	12,000
Elongation in 2 in. or proportionate gage length, per cent	10

Combining strength with fair machining qualities, this general utility bronze is especially good for bushings subjected to heavy loads and severe working conditions.

Specification No. 65, Phosphor Gear Bronze

Composition in percentage:

Copper	88.00 to 90.00
Tin	10.00 to 12.00
Phosphorus	0.10 to 0.30
Lead, Zinc, and Other Impurities, max.	0.50

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	35,000
Yield point, lb. per sq. in.	20,000
Elongation in 2 in. or proportionate gage length, per cent	10

This is a very hard bronze and may be used for gears and worm wheels where the requirements are severe.

Specification No. 66, Bronze Backing for Lined Bearings

Composition in percentage:

Copper	83.00 to 86.00
Tin	4.50 to 6.00
Lead	8.00 to 10.00
Zinc, max.	2.00
Impurities, max.	0.25

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	25,000
Yield point, lb. per sq. in.	12,000
Elongation in 2 in. or proportionate gage length, per cent	10

This composition is recommended as an inexpensive but suitable alloy for bronze-backed bearings.
